RP R.289

INDEX

NAME INDEX

ABBOT, Dr. C. G. : A Solar Variation of 6·6456 Days, 49
Abbot, Dr. E. B. : Theory and Practice of Dyeing, 698
Abraham, R. C. : Awarded a Leverhulme Research Fellowship for 1947, 119
Abrahams, S. C., and Robertson, Prof. J. Monteath : Crystal Structures of *para*-Dinitrobenzene and *para*-Nitraniline, 569
Abushady, H., and others : A Crystalline Principle from *Ammi majus* L., 468
Acheson, R. M., and others : Benziminazoles related to Paludrine, 53
Adam, J. L. : Appointed president of the Institute of Welding, 16
Adams (John Couch) and the Discovery of Neptune (Sir Harold Spencer Jones), 324
Adams, M. E. (Butlin, K. R., and) : Autotropic Growth of Sulphate-reducing Bacteria, 154
Addison, Dr. C. C. : Surface Tension and Detergency, 467
Adrian, Prof. E. D. : The Final Integration, *review*, 623
Advisory Council for Scientific and Industrial Research : Appointment of Prof. P. I. Dee and Sir William Griffiths as members, 530
  Retirement of Sir Lawrence Bragg, Sir John Lennard-Jones, Sir Andrew McCance and Sir Raymond Streat as members, 530
African (East) Agricultural and Forestry Research Organisation : Appointment of Dr. B. A. Keen as director, 184
African (East) Institute of Social Research : Appointment of Lieut.-Colonel W. E. H. Stanner as director, 117
Agar, J. N. : Electrode Processes, 306
Agar, J. N., and Levich, B. : Electrode Processes, 306
Agarwala, B. K., and Chowdri, A. G. : Entropy Fluctuations in Liquid Helium II and the Rayleigh Line, 750
Agricultural Bureaux, Imperial : Joint Publication No. 10, The Use and Misuse of Shrubs and Trees as Fodder, 862
  Name changed to Commonwealth Agricultural Bureaux; 824
Agricultural Research Council : Appointment of Prof. A. C. Chibnall, Prof. G. R. Cameron and Prof. D. Brunt as members, 152
  Retirement of Sir Frank Engledow and Prof. James Gray from membership, 152
  To establish a new Institute of Animal Physiology, 357
  Conference of Plant Breeders at Cambridge, 423
Agricultural and Horticultural Research Station, Long Ashton : Annual Report for 1945, 881
Agriculture and Fisheries, Ministry of : Appointment of Prof. J. A. Scott Watson as chief scientific and agricultural adviser, and director-general of the National Agricultural Advisory Service, 785
  Appointment of Robert Rae as director of the National Agricultural Advisory Service, 785
  Appointment of F. Grant as an under-secretary, 785
  'Appointment of H. G. Lambert to take charge of a new branch to organise the special campaign for grassland development, 785
Aharoni, J. : Antennæ, an Introduction to their Theory, *review* by Dr. H. G. Booker, 277
Ahrens, Dr. L. H. : Geological Age—the Extreme Antiquity of Pegmatites from Manitoba, 874
Ainsworth, Dr. G. C., and others : 'Aerosporin', an Antibiotic produced by *Bacillus aerosporus* Greer, 263
Ainsworth, Dr. G. C. (Rewell, Dr. R. E., and) : Occurrence of *Aspergillus fumigatus* Fresen. in the Lung of an American Bison, 362
Air Council : To set up an Educational Advisory Council for the Royal Air Force, 253
Airan, Dr. J. W. : Mercurochrome as an Indicator in Acid-Alkali Titrations, 88
Akers, Sir Wallace : Metallurgical Problems involved in the Generation of Useful Power from Atomic Energy, 182
Albert, Dr. Adrien : Has joined the staff of the Wellcome Research Institution, 119
Alcock, Dr. F. J. : Appointed chief curator of the National Museum, Ottawa, 495 ; work of, 495
Alders, J. C. : Nederlandsche Baanbrekers der Wetenschap, *review* by Lieut.-Colonel Ernest Tillotson, 449
Aldred, F. C., and Happey, Dr. F. : Activation of Copper by Oxidation and Reduction, 267
Aldrich, Loyal B., and others : Unit for Solar Radiation Work, 327
Alfvén, Prof. H., and Romanus, H. : Valve with Trochoidal Electronic Motion, 614
Allen, Dr. Clifford : The Neurotic Personality, *review*, 887
Allen, Dr. D. N. de G. : Analytical Solution of a Four-cusped Wake, 509
Allen, Prof. J. F. : Liquid Helium and its Properties, 387
  Low-Temperature Physics in North America, 736
Allen, Dr. P. : Awarded a grant from the Leverhulme Research Fellowships, 119
Allen, Dr. W. J. : Appointed a lecturer in physiology in the University of Leeds, 563
Allibone, Dr. T. E. : The Spark Discharge, 110
  At the Jubilee Celebrations of the Discovery of the Electron, 776
Altenburg, Edgar : Genetics, *review* by Dr. C. D. Darlington, 813
Altson, R. A.: A Fungus Parasitic on *Coptotermes curvignathus*, Holmgr., 120
Amadon, Dean : The Weight of the Largest Known Bird, 743
Amazonian Studies, International Institute for : A Projected, 427
American Academy of Political and Social Science : Annals of the, Vols. 248–251, 622
American Chemical Society : Appointment of Dr. William A. Hamor as editor of the Chemical Monographs, 601
American Chemical Society (Division of Industrial and Engineering Chemistry) and the National Research Corporation : Symposium on High Vacuum, 220
American Institute of Physics : Appointment of Cleveland Norcross as assistant director, 601
American Philosophical Society : Symposium on Present-Day Social and Economic Aspects of National Health, 360
  Symposium on U.N.E.S.C.O. and American Participation in its Activities, 360
American Physical Society : Symposium on Low Temperature Physics, 530
  Symposium on Physics of Surface Phenomena, 530
  Symposium on Shock-wave Phenomena, 530
American Society for Testing Materials : Index to the Literature on Spectro-chemical Analysis, Part 2 (1940–1945), 563
Analytica Chimica Acta : Publication of the first number, 394
Anderson, S. G., and others : Mucin as Substrate of Enzyme Action by Viruses of the Mumps Influenza Group, 404
Anderson, William : Risk of Contamination in Experimental Carcinogenesis, 338
  Physico-Chemical Aspects of Chemical Carcinogenesis, 892
Andrade, Prof. E. N. da C. : Liquid Helium and its Properties, 387
  The Poets' View of Newton, *review*, 517
  Newton as Civil Servant, *review*, 589
  Mechanical Properties of Metals, 696
  Obituary of Prof. P. Lenard, 895
Andrewes, C. H., and others : Chemotherapeutic and other Studies of Typhus, 726
Andrews, Jr., Assoc. Prof. Henry N. : Ancient Plants and the World they Lived In, *review* by Prof. John Walton, 734
Animal Health, Imperial Bureau of : Meeting on D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in South Africa, 485
Animal Physiology, Institute of : To be established by the Agricultural Research Council, 357
  Appointment of Prof. I. de Burgh Daly as director, 357
Animal Production, British Society of (British Grassland Society and the) Joint meeting on Grassland and Animal Production, 249
Annals of Botany : Resignation of Prof. V. H. Blackman as editor, 861
  Appointment of Prof. W. H. Pearsall as editor, 861
Anthony, Lieut.-Colonel H. D. : An Introduction to Modern Physics, *review*, 210
Appleton, Sir Edward : Elected an honorary fellow of the Royal Society of Edinburgh, 85
  Earth, Stars and Radio, 283
  New Metals for Old, 308
  Honorary degree of LL.D. of the University of St. Andrews conferred on, 324
  Peaceful Applications of Nuclear Fission, 451
  Awarded the Charles Chree Medal and Prize for 1947 of the Physical Society, 495, 821
  F_2 Ionization and Geomagnetic Latitudes, 642
  Awarded the Nobel Prize for Physics for 1947, 703 ; work of, 703
  Geomagnetism and the Ionosphere, 821
  Science, Government and Industry, 850
Appleton, Sir Edward, and Naismith, R. : Radio Reflexions from Meteoric Ionization, 74
Applied Bacteriologists, Society for : Symposium on the Bacteriology of Water, 583
Applied Biologists, Association of : Symposium on the Classification, Breeding and Preservation of the Potato, 843
Archæological Survey of the Union of South Africa : Report for 1940–46, 785
Arens, Dr. J. F. (Dorp, Dr. D. A. van, and) : Synthesis of Vitamin A Aldehyde, 189
Arkadiev, Prof. V. : A Floating Magnet, 330
  Oscillations of Elementary Magnets, 397
Arkell, Dr. W. J. : The Geology of Oxford, *review* by Prof. H. L. Hawkins, 243
Armour, A. M. : Methods of Crack Detection, 557
Armstrong, Dr. E. B. : Plasma-Electron Oscillations, 713
Armstrong, G. (Butler, Dr. J. A. V., and) : Electrode Processes, 306
Army Educational Corps, Royal : Exhibition of Visual Aids in Adult Education (Colonel J. T. Burgess), 411
  Retirement of Brigadier D. P. J. Kelly as controller, 600
Arnaiz y Freg, Arturo (Vallarta, Prof. Manuel Sandoval, and) : The Name of Element 23, 163
Aronson, Dr. Joseph : Awarded the Alvarenga Prize for 1947 of the College of Physicians of Philadelphia, 564
Arrol, Dr. W. J. : Atomic Energy and the Veto, 460
Arthur, J. R., and Sterling, E. : Use of a Palladium Tube Technique in the Study of the Role of Hydrogen in Combustion Systems, 869
Arts Enquiry : Report on the Factual Film, 513
Ash, C. : Milk, Tinned Foods and Bread, 308
Ashby, Prof. A. W. : British Needs and Resources of Calories, Protein and Calcium, 702
Ashley-Montagu, Prof. M. F. : Adolescent Sterility, *review* by Prof. S. Zuckerman, 591
A.S.L.I.B. : Twenty-second Annual Conference, 293
A.S.L.I.S. : Publication of the first issue of *Information*, 897
Astbury, Prof. W. T. : X-Ray Study of Actin, 388

NAME INDEX

- Astbury, Prof. W. T., and others : Electron Microscope Studies of Normal and Malignant Tissues of High- and Low-Breast-Cancer Strains of Mice, 565
  - Progress in Electron Microscopy, 763
- Astronomical Society, Royal : George Darwin Lecture (Prof. J. H. Oort), 203
  - Geophysical discussion on Atmospheric Turbulence, 859
- Astrup, Dr. Tage, and Birch-Andersen, Aksel : Purification of Renin by means of Protein-Precipitating Agents, 570
  - Fractional Precipitation of Serum Proteins, 637
- Atkins, K. R. : Liquid Helium and its Properties, 386
- Atomic Energy Commission : Second Report of the, 655
- Atomic Energy Research Establishment : Conference on Nuclear Physics, 492
- Atomic Scientists' Association : Travelling Train Exhibition on Atomic Energy, 358, 668
  - Discussion on Atomic Energy and the Veto, 460
- *Atomic Scientists News* : To be made available by a subscription scheme, 863
- Attia, R. : Pests of Stored Foods, 739
- Auber, L., and Burns, Marca : Replacement of Fibres in Sheep, 836
- Audus, Dr. L. J., and Quastel, Prof. J. H. : Toxic Effects of Amino-Acids and Amines on Seedling Growth, 222
  - Selective Toxic Action of Thiosulphate on Plants, 263
- Austin, A. T., and others : Text-book Organic Chemistry, 406
- Australian Defence Scientific Advisory Committee ; To be established by A. P. Rowe, 150
  - Constitution of the, 150
- A.W.A. *Technical Review* (Amalgamated Wireless, Australia, Ltd.), 49
- Axford, D. W. E., and Norrish, Prof. R. G. W. : Mechanism of the Oxidation of Gaseous Formaldehyde, 537
- Aytekin, V. (Cottrell, A. H., and) : Andrade's Creep Law and the Flow of Zinc Crystals, 328

- BACCI, G. : Sex Reversal in *Patella coerulea* L. and *Diodora gibberula* (Lam.), 94
- Bacharach, A. L. : A Modified Microbiological Assay Procedure, 640
- Bacharach, A. L., and Rendle, Theodore (edited by) : The Nation's Food, *review* by Dr. Leslie J. Harris, 242
- Baddeley, G., and others : A Semi-Quinonoid Oxidation Product of 4 : 4-Diethoxydinaphthyl, 187
- Baddiley, J. : Retirement as director of research of Imperial Chemical Industries, Ltd., 528 ; work of, 528
- Bagguley, D. M. S., and Griffiths, Dr. J. H. E. : Paramagnetic Resonance and Magnetic Energy Levels in Chrome Alum, 532
- Bailey, Sir Edward : James Hutton, Founder of Modern Geology (1726–1797), 727
- Bailey, Dr. I. W. : Co-operation versus Isolation in Botanical Research, 804
- Bailey, Dr. J. : New Industrial Techniques and Results of X-Ray Crystallography, 30
- Bailey, Dr. Kenneth : Chemical Basis of Muscle Contraction, *review*, 550
  - Appointed to an Alan Johnston, Lawrence and Moseley Research Fellowship by the Royal Society, 897
- Baimler, M. : Methods of Crack Detection, 557
- Bainbridge, Dr. K. T. : Progress in Nuclear Physics, 492
- Baird, K. M. : Shock Wave in Glass, 24
- Baltsell, George A. (edited by) : Science in Progress (Frank B. Jewett, James B. Macelwane, Donald W. Kerst, Hugh S. Taylor, L. Michaelis, Michael Heidelberger, G. W. Beadle, Peyton Rous, E. C. Stakman, Carl Caskey Speidel, Herbert M. Evans), Fifth Series, *review* by W. L. Sumner, 519
- Bakay, jun., L. : Phylogenesis of the Perivascular Spaces of the Brain, 789
- Baker, Prof. Wilson, and others : Dipole Moments and Structure of the Sydnones, 366
- Bakshi, Vasudev M. (Mahdihassan, Prof. S., and) : A Microbiological Method of Standardizing Liver Extracts, 404
- Baldi, Prof. Edgardo : Microfotografia e Macrofotografia, *review* by Dr. H. H. Hopkins, 553
- Baldwin of Bewdley, Earl : *Death* of, 863
- Balfour-Browne, Prof. W. A. F. : The Possibilities of Natural History, 342
- Balls, Dr. E. W.: Appointed to the University of London readership in anatomy at Middlesex Hospital Medical School, 326
- Balls, Dr. W. Lawrence : First Class of the Order of Agriculture conferred on by the King of Egypt, 152
  - *Obituary* of H. A. Hancock, 356
- Bally, Gustav : Vom Ursprung und von den Grenzen der Freiheit, *review*, 315
- Bamford, J. : Appointed head of the National Foundry College, 705
- Bangham, Dr. D. H. : Appointed director of research laboratories of the British Coal Utilization Research Association, 706
- Bannister, Dr. F. A., and others : Identification of a Calculus from a Hippopotamus, 470
- Banwell, J. C., and others : Radio Reflexions from Meteoric Ionization, 75
- Barakat, Mohamed Zaki, and others : Dimerization Reactions in Sunlight, 401
- Barclay, J. A., and others : 'Water Excretory Threshold' as a Measure of Kidney Efficiency, 432
- Barcroft, Prof. Henry : Appointed to the University of London chair of physiology at St. Thomas's Hospital Medical School, 601, 704 ; work of, 704
- Barlee, J. S. : Awarded a grant from the Leverhulme Research Fellowships, 119
- Barlow, Sir Alan : The Expansion of the Universities, 522
- Barlow, F. : Determination of Benzene Hexachloride in the Blood of Cattle, 719
- Barlow, F. (Hadaway, A. B., and) : Insecticidal Effect of Surface Deposits of D.D.T. on Mud, 363
- Barltrop, J. A., and others : Dipole Moments and Structure of the Sydnones, 366
- Barnes, Dr. H., and Pyefinch, K. A. : Copper in Diatoms, 97
- Barnett, S. A. : Pests of Stored Foods, 739
- Barnett, S. A., and Davis, R.A. : Pests of Stored Foods, 739
- Barnóthy, Dr. J. : Elementary Particles and the Geomagneti
- Barr, Dr. Thomas : Appointed director of research to the Allied Feltmakers Research Association, 150
- Barr, T., and others : A Rapid Method of Analysis for certain Agents, 909
- Barrow, R. F. (Downie, A. R., and) : Silicon Flame Bands, 19
- Barry, Dr. Vincent C. : The Industrial Utilization of Agricul and of Seaweed, 373
- Barry, Dr. Vincent C., and others : Anti-tubercular Activi Ethers and related Compounds, 800
- Bartlett, Prof. F. C. : The Basis of Selection of Students, 522
- Barton, Dr. D. H. R. : Relationship between the Dissociatio Unsymmetrical Dicarboxylic Acids, 752
- Barton-Wright, Dr. E. C. : Milk, Tinned Foods and Bread, 3
- Bashford, T. E. : Milk, Tinned Foods and Bread, 308
  - Infected Cooling Water and its Effect on the Spoilage of 584
- Bastiansen, O., and others : The 'Octa-Benzene', Cyclo (C_8H_8), 128
- Batchelor, G. K. : Atmospheric Turbulence, 861
- Bateman, A. J. : Number of *S*-Alleles in a Population, 337
- Bateman, L. : Co-ordinate Bond Formation by Olefins, 56
- Bates, D. R. (Chapman, Prof. S., and) : The Radiations fron Atmosphere, 250
- Bates, Dr. J. A. V. : The Design and Performance of the Huma
- Bauer, E. : Absorption of Ultrasonic Waves in Liquids, 914
- Bauer, P. T. : Appointed to the University of London reade cultural economics at the London School of Economics,
- Bayard, —. : Absorption of Ultrasonic Waves in Liquids, 914
- Bayley, S. T. : Autoradiography of Single Cells, 193
- Bayliss, Prof. N. S., and David, D. J. : Use of Filter Paper Spectro-chemical Analysis of Solutions, 334
- B.B.C. : Overseas Broadcast of the British Association meeti 461
- Beadle, G. W., and others : Science in Progress, edited by G Baltsell, Fifth Series, *review* by W. L. Sumner, 519
- Beadnell, Surgeon Rear-Admiral C. M. : *Obituary*, 598
- Beattie, Prof. John : British Needs and Resources of Calories, P Calcium, 700
- Beattie, J. R. : Appointed assistant lecturer in physics in the Sheffield, 564
- Beaufoy, S. : Butterfly Lives, *review* by Prof. G. D. Hale Car
- Beaumont's (William) Formative Years, Two Early Notebo (edited by Genevieve Miller), *review* by Dr. E. Ashwort 38
- Bedford, E. J. : Some Orchids of Kent and Sussex, 343
- Bedford College : Appointment of Dr. Margaret M. A. M University of London chair of physiology, 16
  - Title of University of London reader in social economics Mrs. Gertrude Williams, 326
- Begg, A. M., and others : Chemotherapeutic and other Studie 726
- Begg, Dr. Michael : Ascorbic Acid Content of Whale's Milk, 4
- Behounek, Dr. F., and Klumpar, J. : Escape of Thoron from Salts, 640
- Beilby Memorial Fund : Awards, 293
- Bell, Dr. G. H. : Appointed to the chair of physiology in Univer Dundee, 291 ; work of, 291
- Bell, H. T. Montague (edited by) : The Annual Register for the *review*, 735
- Bellamy, Miss E. F. : Retirement from seismological work University Observatory, 220
- Bellamy, H. S. : Built Before the Flood, revised edition, *review* Bushnell, 852
- Bendall, J. R., and others : Displacement Chromatography Exchange Materials, 374
- Benedicks, Dr. Carl, and Skorski, Roman : Upper Yield Point in Bending Tests and Signification, 399
- Benham, W. E. : Spherical Electronic Waves ?, 160
- Bennett, Dr. G. M. : The Isomeric Trithioaldehydes, 502
- Bentley, Eric : The Cult of the Superman, *review* by A. D. R.,
- Benzie, R. J., and others : Nuclear Magnetic Resonance at L tures, 436
- Berlin Technical University, 1947 (B. Donovan), 722
- Bernal, Prof. J. D. : Awarded the Medal of Freedom with Bron the Government of the United States, 513
  - The Missing Factor in Science, 612
  - Publication and Classification of Scientific Knowledge, 649
  - Operational Research in War and Peace, 662
- Bernfeld, Dr. P., and others : Structure of Amylopectin, 90
- Best, Prof. C. H. : Honorary degree of D.Sc. of the Univers conferred on, 152, 249
- Betteridge, Dr. W. : Methods of Crack Detection, 556
- Beverton, R. J. H. : British Needs and Resources of Calories, Calcium, 701
- Bhagavantam, Prof. S., and Suryanarayana, D. : Third-C Coefficients of Crystals, 750
- Bhatia, Dr. A. B. : Awarded an Overseas Science Research for 1947 by the Royal Commissioners for the Exhibi 119
- Bibby, Cyril : An International Union of Family Organisations
- *Bibliography of Seismology* (Dr. Ernest A. Hodgson), Vol. 13, No
- Bickley, Prof. W. G. : Bessel Functions in Bulk, *review*, 773
- Bielschowsky, Dr. F. : Appointed, director of cancer rese Zealand, 564
- Billingham, R. E., and Medawar, Prof. P. B. : Role of Dendritic C Infective Colour Transformation of Guinea Pig's Skin, 61
- *Biochimica et Biophysica Acta* : Publication of the first number, 39
- *Biological Abstracts* : Publication of a new section on Cereals and C Products, 705
- Biological Sciences, International Union of : First post-war meet
  - Election of officers, 462
  - Symposium on the Role of Trace Elements in Plant Physiology, 564
- Birch, Dr. Arthur J. : Reduction of Aniline in Ammonia, 754
- Birch, Dr. S. F., and Oldham, W. J. : Geometrical Configuration of Naphthenes, 368

sen, Aksel (Astrup, Dr. Tage, and) : Purification of Renin
ans of Protein-Precipitating Agents, 570
al Precipitation of Serum Proteins, 637
llege : Appointment of Dr. M. M. Loève to the University of
on readership in applied mathematics, 185
professor of zoology in the University of London conferred on
lastair Graham, 185
reader in pure mathematics in the University of London con-
on Dr. R. G. Cooke, 185
nent of W. G. East to the University of London chair of geo-
, 326
ment of Dr. H. N. Rydon to the University of London reader-
organic chemistry, 326
Mechanism of Ferromagnetic Dispersion, 535
Central Technical College : Opening of new Plastics Labora-
495
and others : The Nile Basin, Vol. 7, The Future Conservation
ie Nile, 215
-Term Plan for the Nile Basin, 611
Classification, Breeding and Preservation of the Potato, 843
Capt. : Atomic Energy and the Veto, 460
of. P. M. S. : Meteors, Comets and Meteoric Ionization, 76
S. : Appointed agricultural officer, Sarawak, 745
of. V. H. : Resignation as editor of the *Annals of Botany*, 861
D. E., and others : Lead Selenide Cells for Infra-Red Spectro-
, 793
Appointed agricultural officer, Trinidad, 745
Charles H. : Elemental Nomenclature, 648
r. A. F. : Elected a foreign associate of the Paris Academy of
es, 85
L. (edited by) : American Philosophic Addresses, 1700–1900,
by Prof. A. D. Ritchie, 37
B. : Mechanism of Colour Vision, 665
, N., and others : Nuclear Magnetic Relaxation, 475
C. M. : The Compounding, Pigmenting and Thickening of
sitex', 50
B. : Appointed superintendent of agriculture, Nigeria, 152
Dr. J. O'M. : Electrode Processes, 307
r J. O'M., and Parsons, Roger : Mercury Tube Effect, 232
ré, et Delaunay, Albert : L'Organisme en lutte contre les
es, *review*, 735
Charles : *Death* of, 863
, and others : Relative Times of Arrival of Bursts of Solar
Different Radio Frequencies, 256
J. : Regulation of the Sodium–Potassium Ratio in Insects, 679
I. G. : Theory of Radio Antennæ, *review*, 277
the Medal of Freedom with Bronze Palm by the Government
United States, 513
nd Allied Trades Research Association, British (University
e London and the) : Research Fellowship for work on the
cure of the human foot, 497
D. : Application of the Method of Steepest Descents to X-Ray
ure Analysis, 196
lax : Liquid Helium and its Properties, 385
Theory of Nuclear Forces (Wolfgang Pauli), *review*, 418
ltural Bureau : To close at the end of 1947, 706
osh, A. K., and) : Occurrence of Microflora in the Salt Pseudo-
Beds, Salt Range, Punjab, 796
and others : Some Experiments with Fast Electrons and Posi-
produced by a 20-MeV. Betatron, 790
., and others : Morphology of *B. megatherium* Bacteriophage,

and others : Dielectric Residual Effects in Titanates, 877
P. G. H. : *Obituary* of Prof. W. W. Watts, 355
ens, Buitenzorg : Appointment of Dr. Frans Verdoorn as an
y staff member, 152
den and Institute, and the Cryptogamical Laboratory, Pavia :
hange periodicals with English institutions, 360
ty of the British Isles : New name of the Botanical Society
ange Club of the British Isles, 824
y of India (Dr. D. Chatterjee), 387
Mechanism of Colour Vision, 666
r. J. C., and others : Use of Radioactive Isotopes in Immuno-
Investigations, 339
F. P., and Grew, K. E. W. : Electrode Processes, 306
. H., and Kenten, R. H. : Uptake of Water by Collagen in
ns of Alkalis and Strong and Weak Organic Bases, 827
: Awarded an Overseas Science Research Scholarship for
the Royal Commissioners for the Exhibition of 1851, 119
: Incentives in Industry, 587
I. C., and others : British Needs and Resources of Calories,
and Calcium, 700
. : Classification, Breeding and Preservation of the Potato,

nical College : Recognition as a university college refused by
iversity Grants Committee, 84
G. (Conway, Prof. Edward J., and) : Source of the Hydrogen
oduced by Gastric Mucosa, 506
rence : X-Ray Crystallographers in Industry, 29
degree of LL.D. of the University of St. Andrews conferred

of Recent Advances in X-Ray Analysis, 394
ion of the Man of Science, 520
c as a member of the Advisory Council for Scientific and
rial Research, 530
ion and Classification of Scientific Knowledge, 649
Dr. J. F. : Appointed honorary director of radiological studies
ving anatomy at the University of Birmingham, 85
berger, Prof. Dr. E. : Röntgenographisch-analytische Chemie,
review by Dr. M. F. Perutz, 208
Dr. E. R., and others : British Needs and Resources of Calories,
Protein and Calcium, 700
Menéndez, E., and Euler, Prof. U. S. v. : Hypertension after Bilateral
Nephrectomy in the Rat, 905
1. H. : Appointed entomologist, Nyasaland, 745
Dr. J. G. M : Action of Per-Acids on the Iso-Octenes, 575

Breuil, Prof. H. : Age of the Baker's Hole Coombe Rock, Northfleet, Kent, 831
Brian, Dr. P. W. : Penicillin and other Antibiotics, 555
Brieger, E. M., and others : Electron Microscopy of Bacteria, 864
Brieger, Dr. N. E. : Progress in Electron Microscopy, 762
Briggs, Dr. Lindsay H., and Sutherland, Maurice D. : A Terpene-type Essential Oil from a Fern (*Paesia scaberula*), 333
Brightman, R. : Names into Cipher, *review*, 175
  Research in Industry, *review*, 346
  Indexing Practice—Trends in German, American and British Chemical Societies' Practice, 615
  Science and Peace, *review*, 733
Brindley, Dr. G. W. : New Methods and Results of X-Ray Analysis, 30
Briner, Prof. Emile : Elected a *correspondant* for the Section of Chemistry of the Paris Academy of Sciences, 51
Brinkmann, Jun., August : Two New Antarctic Leeches, 756
British Association for the Advancement of Science : Dundee Meeting of the, 182, 324
  Presidential Address to the Dundee Meeting (Sir Henry Dale), 280
  Election of Sir Henry Tizard as president for 1948, 324
  Appeal by Sir Henry Dale for a Development Fund, 324
  Overseas Broadcast of the Dundee meeting, 461
  Discussion on the Education of the Man of Science, 520
  Discussion on the United Nations Educational, Scientific and Cultural Organisation, 689
British Association for the Advancement of Science (Section A, Mathematics and Physics) : Symposium on the Peaceful Applications of Nuclear Fission, 451
British Association (Sections B, Chemistry, I, Physiology, and K, Botany) : Symposium on Penicillin and other Antibiotics, 554
British Association (Section C, Geology) : Discussion on Geology and the Future of Coal Supplies, 593
British Association (Sections F, Economics, and J, Psychology) : Symposium on Incentives in Industry, 587
British Association (Section J, Psychology) : Discussion on Selection for Management, 512
British Association for the Advancement of Science (Division of the Social and International Relations of Science) : Discussion on Operational Research in War and Peace, 660
British Boot, Shoe and Allied Trades Research Association (University College London and the) : Research Fellowship for work on the structure of the human foot, 497
British Broadcasting Corporation : Overseas Broadcast of the British Association meeting at Dundee, 461
British Bryological Society : Annual General Meeting, 428
  Election of officers, 428
British Ceramic Society: Appointment of A. T. Green as honorary general secretary, 530
British Coal Utilization Research Association : Appointment of Dr. D. T. A. Townend as director-general, 706
  Appointment of Dr. D. H. Bangham as director of research laboratories, 706
  Appointment of Dr. E. G. Ritchie as director of engineering laboratories, 706
  Appointment of J. S. Hales as director of domestic appliance laboratories, 706
  Appointment of H. T. Hathaway as secretary and finance officer, 706
British Cotton Industry Research Association : Award of a Shirley Fellowship to B. J. Mason, 428
British Council : Appointment of Dr. W. T. H. Williamson as lecturer in charge of the Department of Soil Science in the University of Aberdeen, 428
  Appointment of Dr. H. V. Walters as science officer for China, 529
British Foundrymen, Institute of : Tenth Edward Williams Lecture (Sir Edward Appleton), 308
British Grassland Society and the British Society of Animal Production : Joint meeting on Grassland and Animal Production, 249
British Hat and Allied Feltmakers Research Association : Appointment of Dr. Thomas Barr as director of research, 150
British Herpetological Society : Election of officers, 394
British Industries, Federation of : Regional conference on Research and the Progress of Industry in Scotland, 341
British Industries, Federation of (Industrial Research Secretariat) : Scientific and Industrial Research in British Industry, 770
British Institute of Radiology : Twenty-fourth Mackenzie Davidson Memorial Lecture (Dr. John H. Lawrence), 51
British Iron and Steel Research Association : Opening of Sketty Hall Laboratories, 100
  Activities of the, 233
  New Physics Laboratories opened by Lord Rayleigh, 530, 684
British Medical Bulletin : Special number on Chemical Carcinogenesis, 375
British Museum (Natural History) : Retirement of Sir Clive Forster-Cooper as director, 220, 252
  Appointment of N. B. Kinnear as director, 220, 252
British Mycological Society : Election of Prof. A. E. Muskett as president for 1948, 863
British Non-Ferrous Metals Research Association : Laboratory Buildings and Facilities of the, 595
British Postgraduate Medical School : Degree of D.Sc. o the University of London conferred on Prof. E. J. King, 185
  Appointment of Dr. Russell Fraser to the University of London readership in medicine, 601
British Rayon Research Association : Appointment of John Wilson as director of research, 706
British Rheologists' Club : Annual Conference of the, 844
British Rheologists' Club and the South-Western Branch of the Chemical Society : Discussion on the Chemistry and Rheology of Clay, 511
British School of Archæology at Athens : Annual Report of the Committee of the, 601
British Science Writers, Association of : Formation and aims of the, 634
British Scientific Instrument Research Association : New laboratories of the, 15, 199
British Social Hygiene Council : Conference on Society and the Individual, 706
  Conference on Biology in Education, 785
  International School in Social Biology, 803

British Society of Animal Production (British Grassland Society and the) : Joint Meeting on Grassland and Animal Production, 249
British Society for International Understanding : Teacher's Guide to the United Nations Organisation, 529
British Society of Soil Science : Conference on Problems of Soil and Land Classification, 686
British Standards Institution : Election of Lord McGowan as president, 16
  Election of Sir Clifford Paterson as chairman of the General Council, 16
British-Kenya Miocene Expedition, 1947 (Prof. W. E. Le Gros Clark), 891
Broad, Prof. C. D. : Honorary degree of LL.D. in the University of Aberdeen conferred on, 51
Broadhead, Edward : Appointed lecturer in zoology in the University of Leeds, 563
Broda, Dr. E. : Adsorption Isotherm of a Photographic Emulsion for Uranyl and Lead Ions, 231
Brodetsky, Prof. S. : The Proposal to Establish a Representative Universities Council, 523
Bromberg, Y. M., and others : Determination of Bilirubin in the Umbilical Blood as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn, 192
Brønsted, Prof. J. N. : Honorary degree of the University of London conferred on, 85
Brooke, Justin : Peach Orchards in England, *review*, 814
Brooks, Dr. C. E. P. : A Long-Term Plan for the Nile Basin, 215
  Obituary of Dr. Ellsworth Huntington, 666
Broom, Dr. R., and Robinson, J. T. : Jaw of the Male Sterkfontein Ape-man, 153
  Further Remains of the Sterkfontein Ape-man, *Plesianthropus*, 430
Broomhead, J. M., and Nicol, A. D. I. : Crystal Structures of Zinc and Magnesium Benzene Sulphonates, 795
Broström, K. J., and others : Gamma-Ray Yield Curves of Separated Neon Isotopes Bombarded with Protons, 498
Brown, A. Lang : Awarded the Medal of Freedom with Bronze Palm by the Government of the United States, 513
Brown, Annie M., and others : 'Aerosporin', an Antibiotic produced by *Bacillus aerosporus* Greer, 263
Brown, Dr. C. J. : New Industrial Techniques and Results of X-Ray Crystallography, 31
Brown, Dr. D., and Lyttleton, J. W. : Photo-electric Fourier Transformer and its Application to Sound-Films, 709
Brown, E. H. Phelps : Appointed to the University of London chair of economics of labour at the London School of Economics, 185
Brown, Miss E. M. : Awarded a grant from the Leverhulme Research Fellowships, 119
Brown, Frederick : Title of reader of commerce in the University of London conferred on, 16
Brown, J. B. : Liquid Helium and its Properties, 386
Brown, J. B., and Mendelssohn, Dr. K. : A New Technique for Studying the Helium Film, 670
Brown-Séquard (Charles-Édouard), a Nineteenth Century Neurologist and Endocrinologist (Prof. J. M. D. Olmsted), *review* by Dr. James Marshall, 383
Brownlee, G., and others : 'Aerosporin', an Antibiotic produced by *Bacillus aerosporus* Greer, 263
Bruck, Dr. : Progress in Electron Microscopy, 763
Brunt, Prof. D. : Appointed a member of the Agricultural Research Council, 152
Brunn, Dr. Anton Fr. : *Obituary* of K. H. Stephensen, 82
Bryant, P. M., and Coates, G. E. : Electrode Processes, 306
Bryce, W. A. : Awarded an Overseas Science Research Scholarship for 1947 by the Royal Commissioners for the Exhibition of 1851, 119
Bryological Society, British : Annual General Meeting, 428
  Election of officers, 428
Brzezinski, A., and others : Determination of Bilirubin in the Umbilical Blood as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn, 192
Buchner, Prof. P. : Symbiosis in *Oliarius*, 264
Buckley, Dr. H. : Appointed to be in charge of the Scottish Office of the Department of Scientific and Industrial Research, 358
Bullard, Dr. E. C. (Slichter, Prof. Louis B., and) : Frenkel's Views on the Origin of Terrestrial Magnetism, 157
Bulletin of Atomic Scientists : Bibliography of Atomic Energy (M. C. Leikend), 426
Bullough, Dr. W. S. : Hermaphroditism in the Lower Vertebrates, 9
  Practical Vertebrate Anatomy, *review*, 813
  Evolution on Galapagos, *review*, 853
Bunn, C. W. : New Methods and Results of X-Ray Analysis, 30
  Chemical Crystallography, *review* by Dr. Dorothy Crowfoot, 173
Burcham, Dr. W. E. : The One Million-Volt Accelerating Equipment of the Cavendish Laboratory, Cambridge, 316
  Progress in Nuclear Physics, 494
Burgen, A. S. V., and others : Physiological Effects of Alkyl Polyphosphates, 760
Burgers, Prof. W. G. : Growth of 'Stimulated Crystals' and Rate of Nucleation during Recrystallization of Aluminium, 398
  Mechanical Properties of Metals, 696
Burgess, Colonel J. T. : Visual Aids in Adult Education—Royal Army Educational Corps Exhibition, 411
Burhop, Dr. E. H. S. : Control of Atomic Energy, 910
Burnet, Dr. F. M. : Awarded a Royal Medal for 1947 of the Royal Society, 704, 839
Burnet, Dr. F. M., and others : Mucin as Substrate of Enzyme Action by Viruses of the Mumps Influenza Group, 404
Burns, Marca (Auber, L., and) : Replacement of Fibres in Sheep, 836
Burns, Prof. William : Appointed to the University of London chair of physiology at Charing Cross Hospital Medical School, 326, 561
Burton, Prof. E. F., and others : Specimen Changes due to Electron Bombardment in the Electron Microscope, 565
Burton, Dr. Harold : Appointed to the University of London chair of chemistry at King's College of Household and Social Science, 185
Busbridge, W. G. : Awarded the Medal of Freedom by the Government of the United States, 513
Bush, H. D. : Appointed assistant lecturer in physics in the University of Sheffield, 85
Bushnell, G. H. S. : Noah's Nightmare, *review*, 852
Butler, Dr. C. C. (Rochester, Dr. G. D., and) : Evidence for the of New Unstable Elementary Particles, 855
Butler, Dr. J. A. V. : Thermodynamics and Humanism, *review*, 72
  Physical Chemistry for Colleges (Prof. E. B. Millard), sixt *review*, 592
  Fundamental Principles of Physical Chemistry (Prof. Carl and Prof. Samuel H. Maron), *review*, 592
Butler, Dr. J. A. V., and Armstrong, G. : Electrode Processes,
Butler, Dr. J. A. V., and Stephen, Miss J. M. L. : An Apparatus tive Electrophoresis, 469
Butler, Dr. Nicholas Murray : *Death* of, 821
Butlin, K. R., and Adams, M. E. : Autotrophic Growth of Sulph Bacteria, 154
Byers, A., and Hickinbottom, Dr. W. J. : Oxidation of Olefins, Acid, 402

CADMAN, C. H., and Hill, A. R. : Aphid Vectors of European Viruses, 837
Cady, Prof. Walter Guyton : Piezo-Electricity, *review* by Dr. P. 348
Cahusac, A. B. : Appointed assistant conservator of forests, Ug
Calder, K. L. : Atmospheric Turbulence, 861
Californian Academy of Sciences : Annual Report for 1946, 863
California Institute of Technology : Appointment of Prof. Li as George Eastman visiting professor in the University 16
Callan, Dr. E. McC. : Technique for Rearing Thrips in the Labo
Calvert, Dr. H. T. : *Obituary* by Dr. A. Parker, 597
Cambridge Philosophical Society : Open meeting to celebrate of the Discovery of the Electron, 704
Cameron, Prof. A. T. : *Death* of, 599
Cameron, Prof. G. R. : Appointed a member of the Agricultura Council, 152
Campbell, J. G., and others : β-Glucuronidase and Tissue Prolife
Campbell, Dr. Neil : Modern Organic Chemistry, *review*, 484
  Text-book Organic Chemistry, 875
Campbell, Rosa M. (Kosterlitz, Dr. H. W., and) : Composition ture of the Liver Cell in Pregnancy, 676
Canac, L. : Musical Acoustics, 766
Cansdale, George G. : Appointed assistant superintendent of the Gardens, London, 326
Capper, H. : Methods of Crack Detection, 557
Caribbean Commission : Appointment of a Sub-Committee of ists, 634
Caribbean Research Council : Publications dealing with Cr Caribbean, 562
Carman, Dr. P. C. : Slip Flow in Granular Beds, 301
Carnegie United Kingdom Trust : Grant of £5,000 to the Coun Promotion of Field Studies for the completion of the Fi Field Centre, 84
Carpenter, Prof. G. D. Hale : British Butterflies, *review*, 278
  Protective Coloration in Insects, and its Interpretation, 34
  'Mimicry' in Fishes, 508
Carsdale, George S.: Appointed assistant superintendent of the Gardens, London, 326, *erratum*, 360
Carslaw, Prof. H. S., and Jaeger, J. C. : Conduction of Heat *review* by Prof. L. Rosenhead, 886
Carter, Charles F. : Reservoirs of Water, Wheat and Gold, *revie*
Carvalho, Hervasio G. de : The Thermochor, a New Additive stitutive Property, 370
Casagrande, Leo : Structures Produced in Clays by Electric Pot their relation to Natural Structures, 470
Case Institute of Technology : Appointment of Dr. T. K. president, 83
Castillo, J. del, and others : Physiological Effects of Alkyl Polyp 760
Castro, Duarte de (Malheiros, Nydia, and) : Chromosome N Behaviour in *Luzula purpurea* Link, 156
Cathcart, Prof. E. P. : Retirement from the regius chair of in the University of Glasgow, 117 ; work of, 117
Catherall, R. (Yates, H. G., and) : Combination Tones, 198
Cauchois, Y., et Hulubei, H. : Tables de constantes et données n I, Constantes sélectionées, longueurs d'onde des émissio discontinuités d'absorption X, *review* by Dr. H. Lipson, 6
Cavendish Laboratory, Cambridge : Lecture on the History Alex. Wood), 704
  The One Million-Volt Accelerating Equipment of the (Burcham), 316
Cell Biology, International Society for : Foundation of the, 784
  Election of Prof. J. Runnström as president, 784
Ceramic Society, British : Appointment of A. T. Green as honor secretary, 530
Ceylon, National Museums of : Annual Report for 1945, 669
Chacko, L. (Clark, Prof. W. E. Le Gros, and) : A Possible Centr ism for Colour Vision, 123
Chain, Dr. E. : Penicillin and other Antibiotics, 554
Chakravarti, Dr. R. N., and Robinson, Sir Robert : Oxidatio strychnine, 18
Chakravarty, Dr. K. M., and Sen, Ranjit : X-Ray Diffraction S Nickel-Thoria-Kieselguhr Catalyst for Fischer-Tropsch Sy
Challens, W. J. : Awarded the Medal of Freedom by the Gov the United States, 513
Chalmers, Dr. B. : Mechanical Properties of Metals, 696
Chambers, R., and Zweifach, B. W. : Organisation of the Capilla tion, 443
Champion, Prof. H. G. : British Forest Trees, *review*, 106
Chantrenne, H. : Hippuric Acid Formation from Glycine and phosphate, 603
Chapman, Dennis : Incentives in Industry, 588
Chapman, Prof. S. : The Magnetic Field of the Moon?, 395
Chapman, Prof. S., and Bates, D. R. : The Radiations from Atmosphere, 250
Chardin, Pierre Teilhard de : Elected a *correspondant* for the Mineralogy of the Paris Academy of Sciences, 51

Charing Cross Hospital Medical School : Appointment of Dr. William Burns to the University of London chair of physiology, 326, 561
  Appointment of Prof. W. J. Hamilton to the University of London chair of anatomy, 462
Chatterjee, Dr. D. : Botany of the Wild and Cultivated Rices, 234
  The Botanical Survey of India, 387
  Wild and Cultivated Rice, 756
Chemical Engineers, Institution of : Sixth Hinchley Memorial Lecture (Dr. R. V. Southwell), 462
Chemical Industry, Society of (Food Group and the Midland Section) : Joint meeting on Pollution by Trade Wastes from Food Industries, 200
Chemical Industry, Society of (Food Group), and the Food and Nutrition Section of the Royal Sanitary Institute : Joint meeting on Milk, Tinned Foods and Bread, 307
Chemical Research Laboratory, Teddington, 133
Chemical Society : The (Dr. F. Sherwood Taylor), 6
  Centenary celebration meetings, 14
  Centenary of the, 245
  Centenary Address to the (Prof. C. N. Hinshelwood), 245
  Ernst Julius Cohen Memorial Lecture (Prof. F. G. Donnan), 360
  Tilden Lecture (Prof. E. G. Cox), 428
  Centenary Exhibition at the Science Museum, 477
  Pedler Lecture (Sir Ian Heilbron), 706
Chemical Society, 1841–1941 (Tom Sidney Moore and James Charles Philip), *review* by Prof. John Read, 657
Chemical Society, South-Western Branch (Rheological Club and the) : Discussion on the Chemistry and Rheology of Clay, 511
Chemistry, International Union of : Meetings of the, 14
Chemistry, Royal Institute of (Manchester and District Section) : Fourth Dalton Lecture (Dr. D. T. A. Townend), 530
Chemistry, Royal Institute of (Dublin Section), and the Irish Chemical Association : Colloquium on the Industrial Utilization of Agricultural Products and of Seaweed, 373
Chen, Jui-Ming : Induced Polycythæmia by *l*-Ascorbic Acid in Albino Mice, 681
Chennells, Mary, and others : Physiological Effects of Alkyl Polyphosphates, 760
Chennells, Mary, and Wright, Prof. Samson : Central Excitant Action of Diisopropylfluorophosphonate, 503
Cherwell, Lord : Liquid Helium and its Properties, 387
Cheshunt Experimental and Research Station : Thirty-first Annual Report, 915
Chevalley, Claude : Theory of Lie Groups, I, *review* by Dr. A. G. Walker, 854
Chibnall, Prof. A. C. : Appointed a member of the Agricultural Research Council, 152
Chinese Association for the Advancement of Science, and others : Resolutions on the control of atomic research and on the development of scientific research in China, 600
  Joint Annual Conference, 600
Chiodi, Dr. Hugo, and Sammartino, Rodolfo A. : Nephrotoxic and Renotropic Effects of Lead on White Rats and its Prevention by *B.A.L.*, 680
Chirnside, R. C. : Physical Methods of Gas Analysis, 441
Chodnik, Dr. K. S. : Cytology of Alimentary Tract and Associated Glands of the Fowl, *Gallus domesticus*, 62
Chorley, Lord : The Proposal to Establish a Representative Universities Council, 523
Chowdhury, K. A. : Initial Parenchyma Cells in Dicotyledonous Woods, 609
Chowdri, A. G. (Agarwala, B. K., and) : Entropy Fluctuations in Liquid Helium II and the Rayleigh Line, 750
Chromosoma : Resumption of publication, 863
Chughtai, I. D., and others : Detection of Acetic Acid in *A. niger* Growing on a Glucose Medium, 573
Chymia : Annual publication on the history of chemistry (University of Pennsylvania Press), 84
  Publication to be sponsored by the Edgar Fahs Smith Memorial Collection at the University of Pennsylvania, 292
Cicardo, V. H. (Izzo, Prof. R. A., and) : Gonads and Experimental Tuberculosis, 155
Cinneide, R. Ó. : Furansulphonamides, 260
Civatte, A., et autres : Précis de dermatologie, cinquième édition par A. Civatte, *review* by Dr. James Marshall, 592
Civil Aviation, Minister of : Appointment of advisers in science, business and industrial relations, 185
Civil Engineers, Institution of : Election of Council for 1947–48, 669
  Christmas lectures on High-Speed Flying and the Airport, 824
Clapperton, Robert Henderson, and Henderson, William : Modern Paper-Making, third edition, *review* by Dr. Julius Grant, 814
Clare, K. E. : Effect of Cetyl Pyridinium Bromide on the Water Absorption and Swelling of Soil, 828
Clarendon Laboratory, Oxford : Conference on the Properties of Liquid Helium, 385
Clark, Elna M., and others : Morphology of *B. megatherium* Bacteriophage, 755
Clark, F. le Gros : British Needs and Resources of Calories, Protein and Calcium, 700
Clark, Dr. H. L. : *Obituary* by Dr. D. Dilwyn John, 391
Clark, Dr. J. G. D. : Awarded a grant from the Leverhulme Research Fellowships, 119
Clark, Dr. L. N. O. : The Chemistry and Rheology of Clay, 512
Clark, Prof. W. E. Le Gros : Mechanism of Colour Vision, 665
  The British-Kenya Miocene Expedition 1947, 891
Clark, Prof. W. E. Le Gros, and Chacko, L. : A Possible Central Mechanism for Colour Vision, 123
Clarke, G. R. : Problems of Soil and Land Classification, 687
Claughton, Harold : Retirement from the principalship of the University of London, 51
Clayson, D. H. F. : Milk, Tinned Foods and Bread, 308
Clegg, J. A. : Detection by Radar of a New Meteor Shower, 118
Clegg, J. A., and others : Radio Reflexions from Meteoric Ionization, 75
  Radio Echoes from the Aurora Borealis, 372
Clemo, Prof. G. R., and Daglish, A. F. : Phenazine Synthesis, 752
Coal Utilization Research Association, British : Appointment of Dr. D. T. A. Townend as director-general, 706
  Appointment of Dr. D. H. Bangham as director of research laboratories, 706
  Appointment of Dr. E. G. Ritchie as director of engineering laboratories, 706
  Appointment of J. S. Hales as director of domestic appliance laboratories, 706
  Appontment of H. T. Hathaway as secretary and finance officer, 706
Coase, R. H. : Appointed to the University of London readership in economics at the London School of Economics, 185
Coates, G. E. (Bryant, P. M., and) : Electrode Processes, 306
Cobb, John : New World Speed Record for Motor-cars, 428
Cochran, Dr. W. : New Methods and Results of X-Ray Analysis, 30
Cockcroft, Prof. J. D. : Liquid Helium and its Properties, 387
  Peaceful Applications of Nuclear Fission, 451
  Progress in Nuclear Physics, 492
Cohen, Dr. J. A. : Effect of Injection of Adrenaline on the Anaerobic Glycolysis of Rat Diaphragm, 871
Cole, Fay-Cooper : The Peoples of Malaysia, *review* by Prof. J. H. Hutton, 732
Cole, G. F. : Appointed secretary of the Illuminating Engineering Society, 51
Cole, H. : Constitution of Alkali Halide-Borate Glasses, 191
Cole, J. F. I. (Rutherglen, J. G., and) : A Radio-Frequency Ion Source with High Percentage Yield of Protons, 545
College of Physicians of Philadelphia : Alvarenga Prize for 1947 awarded to Dr. Joseph Aronson, 564
Collinge, Dr. Walter E. : Abnormal Reproduction in Woodlice, 509
Colonial Development Corporation : Government proposal to establish a (Creech Jones), 171
Colonial Office : Appointments and promotions, 51, 152, 745
Comfort, Dr. Alex : Lipochromes in the Ova of *Pila*, 333
Commission on Freedom of the Press : A Free and Responsible Press, a General Report on Mass Communication, 312
Common, Dr. R. H., and others : Gonadal Hormones and Mineral Balance in the Domestic Fowl, 541
Commonwealth Agricultural Bureaux : New name of the Imperial Agricultural Bureaux, 824
Commonwealth Fund of New York : Fellowships, 744
Compton, Dr. Karl T. : Awarded the Public Welfare Medal for 1947 of the Marcellus Hartley Fund of the U.S. National Academy of Sciences, 169
Congdon, J. L. : Appointed agricultural officer, Aden, 152
Constable, Prof. F. H., and Tegul, S. : Silicic Acid, 55
Conway, Prof. Edward J., and Brady, Thomas G. : Source of the Hydrogen Ions produced by Gastric Mucosa, 506
Conway, N. S., and others : Utilization of Citric Acid by some So-called Citrate-non-utilizing Bacteria, 573
Conybeare, —. : Atomic Energy and the Veto, 460
Cook, A. H., and others : Production of Antibiotics by *Fusaria*, 31
Cook, Prof. J. W. : Chemical Carcinogenesis, 375
  Obituary of Prof. J. Masson Gulland, 702
Cook, Dr. W. R. Ivimey (Hentschel, C. C., and) : Biology for Medical Students, fourth edition, *review* by A. S., 853
Cooke, A. H., and others : Nuclear Magnetic Resonance at Low Temperatures, 436
Cooke, G. E. : Resignation as lecturer of civil engineering in the University of Sheffield, 745
Cooke, Dr. R. G. : Title of reader in pure mathematics in the University of London conferred on, 185
Cooke, Dr. W. T., and others : 'Water Excretory Threshold' as a Measure of Kidney Efficiency, 432
Cori, Prof. Carl F. and Mrs. Gerty T. : Awarded one-half of the Nobel Prize for Physiology and Medicine for 1947, 599 ; work of, 599
Cornforth, Dr. J. W., and Robinson, Sir Robert : Towards the Synthesis of Cholesterol, 737
Cosandey, Prof. Florian : Les plantes et la vie, *review*, 814
Cosslett, Dr. V. E. : Progress in Electron Microscopy, 762, 763
Cosslett, Dr. V. E., and others : Electron Microscopy of Bacteria, 864
Costain, C. C. : Awarded an Overseas Science Research Scholarship for 1947 by the Royal Commissioners for the Exhibition of 1851, 119
Costain, Dr. W., and Cox, Prof. E. G. : Structure of Dimethylnitramine, 826
Cotton, R. T. : Pests of Stored Foods, 739
Cotton Industry Research Association, British : Award of a Shirley Fellowship to B. J. Mason, 428
Cottrell, A. H. : Mechanical Properties of Metals, 696
Cottrell, A. H., and Aytekin, V. : Andrade's Creep Law and the Flow of Zinc Crystals, 328
Cottrill, Frank : Winchester City Museums (1847–1947), 253
Coulson, Prof. S. A., and others : Interaction Terms in Molecular Vibrations, 793
Count, Prof. E. W. : Brain and Body Weight in Man, 805
Court, Arnold, and others : Unit for Solar Radiation Work, 327
Courtauld, S. A. : *Death* of, 821
Courtaulds, Ltd. : Grant of £60,000 for building and equipping a Division of Rayon Technology in the Department of Textile Industries of the University of Leeds, 186
Cowling, Prof. T. G. : Elementary Particles and the Geomagnetic Field, 847
Cox, Prof. E. G. : Training of X-Ray Crystallographers in Polytechnics and Universities, 29
  Crystallographic Technique and its Chemical Significance, 428
Cox, Prof. E. G. (Costain, Dr. W., and) : Structure of Dimethylnitramine, 826
Cox, Dr. H. Roxbee : Awarded the American Medal of Honour with Silver Palm by the Government of the United States, 291

Fahmy, Prof. I. R., and others : A Crystalline Principle from *Ammi majus* L., 468
Fairbrother, Dr. F. : Colour of Iodine Solutions, 87
Fairley, Prof. N. Hamilton : Appointed a member of the Medical Research Council, 293
Falcon, L. N. (Lees, Dr. G. M., and) : Geology and the Future of Coal Supplies, 594
Family Organisations : International Union of (Cyril Bibby), 183
Faraday Society : Discussion on Electrode Processes, 306
  General discussion on the Labile Molecule, 326, 778
  General discussion on the Physical Chemistry of Process Metallurgy, 564
Fargher, Dr. R. G. : Theory and Practice of Dyeing, 698
Farmer, T. H., and others : Production of Antibiotics by *Fusaria*, 31
Farnsworth, —. : Mechanism of Colour Vision, 666
Farrington, G. H. : Theoretical Foundations of Process Control, 340
Feather, Prof. N. : Radiations from Uranium (239) and Neptunium (239), 749
Featherstone, Dr. H. W. : Honorary degree of LL.D. of the University of Edinburgh conferred on, 668
Federal Technical Institute, Zurich : Hanbury Gold Medal for 1947 of the Pharmaceutical Society of Great Britain awarded to Dr. Hans Flück, 706
Federation of British Industries : Regional conference on Research and the Progress of Industry in Scotland, 341
Federation of British Industries (Industrial Research Secretariat) : Scientific and Industrial Research in British Industry, 770
Feindel, W. H., and others : Significance of Multiple Innervation of Cutaneous Pain 'Spots' in relation to the Quality of Pain Sensibility, 27
Fell, Dr. E. W. : X-Ray Diffration Studies of Yielding in Mild Steel, 259
Ferguson, Prof. A. L. : Electrode Processes, 306
Fermor, Sir Lewis : *Obituary* of Sir Thomas Holland, 11
Ferranti, V. Z. de : Automatic Regulators and Servo Mechanisms, 341
Ferrari, H. : Appointed lecturer in mining in the University of Sheffield, 745
Ferretti, Dr. B. : Fundamental Physical Theory, 628
Ferretti, Dr. B., and Peierls, Prof. R. E. : Radiation Damping Theory and the Propagation of Light, 531
Field Studies, Council for the Promotion of : Gift of £6,000 from the Worshipful Company of Goldsmiths for a residential field study and research centre at Malham Tarn House, 84
  Grant of £5,000 from the Carnegie United Kingdom Trust to complete the establishment of the Flatford Mill Field Centre, 84
  Acceptance by Prof. A. G. Tansley of the office of president, 84
Figge, Dr. Frank H. J. : Cosmic Rays and Cancer, 823
Finch, Prof. G. I. : Electrode Processes, 306
Findlay, Prof. Alexander : To visit India and Pakistan, 743
Findlay, Prof. Alexander, and Mills, William Hobson (edited by) : British Chemists, *review* by Prof. John Read, 657
Fink, K., and others : Application of Filter Paper Partition Chromatography to Radioactive Tracer Studies, 801

Fink, Dr. R. M., and others : Application of Filter Paper Partition Chromatography to Radioactive Tracer Studies, 801
Finn, Capt. P. B. : Appointed staff surveyor, Kenya, 745
Finney, D. J. : Errors of Estimation in Inverse Sampling, 195
Fischer, Prof. Hans : *Obituary* by Dr. S. F. MacDonald, 494
Fishenden, Dr. Margaret : Appointed to the University of London readership in applied heat at the Imperial College of Science and Technology, 16
Fisher, Helen Dwight, and others (edited by) : The Life of a Chemist, Memoirs of Vladimir N. Ipatieff (Prof. D. M. Newitt), 43
Fisher, Prof. R. A. : The Design of Experiments, fourth edition, *review* by K. M., 775
Number of Self-Sterility Alleles, 797
Fisher, Prof. R. A., and Martin, V. C. : Spontaneous Occurrence in *Lythrum salicaria* of Plants Duplex for the Short-style Gene, 541
Fitzgerald, Prof. Walter : A Development Plan for Uganda, *review*, 691
Fitzwilliam Museum, Cambridge : Annual Report for 1946, 823
Fleming, Sir Alexander : Awarded the Gold Medal of the Royal Society of Medicine, 51
Elected an honorary fellow of the Royal Society of Edinburgh, 85
Honorary degree of LL.D. of the University of St. Andrews conferred on, 324
Penicillin and other Antibiotics, 554
Fleming, Sir Arthur : The Education of the Man of Science, 521
Fleming, Dr. G. W. T. H. : The Mentally Ill in America (Albert Deutsch), *review*, 279
Fletcher, Dr. H. R. : The Institute of Seaweed Research, 662
Fleure, Prof. H. J. : The Population of the Soviet Union, *review*, 888
Flood, A. E., and others : Quantitative Estimation of Mixtures of Sugars by the Paper Chromatogram Method, 86
Flood, D. T. : The Production, Properties and Uses of Seaweed Rayon, 373
Florey, Sir Howard : Awarded the Gold Medal of the Royal Society of Medicine, 51
Floyd, W. F., and others : Physiological Effects of Alkyl Polyphosphates, 760
Flück, Dr. Hans : Awarded the Hanbury Gold Medal for 1947 of the Pharmaceutical Society of Great Britain, 706
Foister, C. E. : Classification, Breeding and Preservation of the Potato, 843
Folan, M. E. : Persistence of a Substance with Blood Groups A and O Specificity in Commercial Fluid Hog Stomach Extract, 790
Follett, D. H. : Handbook to the Electron Jubilee Exhibition at the Science Museum, 460
Folley, Dr. S. J., and Greenbaum, A. L. : Decrease in the Arginase of the Liver and Mammary Gland in Adrenalectomized Lactating Rats as compared with Pair-fed Controls, 364
Food, Minister of : Appointment of Dr. Norman C. Wright as chief scientific adviser to the, 530, 667
Food, Ministry of : Exhibition of German Food Industry in War-time, 462
Food Investigation Board : Appointment of Sir Frank Engledow as chairman, 785
Food and Agriculture Organisation of the United Nations : Conference on Infestation of Stored Foodstuffs, 51, 739
Report of the International Timber Conference, 878
Foot-and-Mouth Disease Research Committee : Reconstituted by the Minister of Agriculture and Fisheries, 151

Foreign Office : Report of the Inter-departmental Commission of Enquiry on Oriental, Slavonic, East European and African Studies, 205
Forestry Commission : Bulletin No. 17, The Cultivation of the Cricket Bat Willow, 807
Forrest, H. S., and others : Antagonistic Effect by certain Growth-Stimulants of the Tuberculostatic Activity of 5-Amino-2-butoxypyridine, 94
Forster-Cooper, Sir Clive : Retirement as director of the British Museum (Natural History), 220, 252 ; work of, 252
Obituary by Prof. D. M. S. Watson, 425
Forsyth, Dr. W. G. C., and Fraser, G. K. : Freezing as an Aid in the Drying and Purification of Humus and Allied Materials, 607
Fortescue, R. L. : Progress in Nuclear Physics, 493
Fosdick, Dr. Raymond B. : The Year's Work of the Rockefeller Foundation, 103
Foster, C. E. : High-Speed Flying and the Airport, 824
Foster, G. L. (Lilley, H. S., and) : Interaction of Styrene with Magnesium Perchlorate and other Salts, 131
Foster, Dr. Laurence Standley (Weaver, Elbert Cook, and) : Chemistry for our Times, *review*, 142
Fouché, M. : Musical Acoustics, 765
Fouché, P. : Musical Acoustics, 766
Foundry College, National : Establishment of the, 705
Appointment of J. Bamford as head of the, 705
Fournet, G. (Guinier, Dr. A., and) : Correction of Measurements of Low-Angle X-Ray Scattering, 501
Fowell, R. R. : British Folliculinidæ (Ciliata, Heterotricha), 28
Fowles, G. : Lecture Experiments in Chemistry, third edition, *review* by A. C. C., 814
Fox, Sir Cyril S. : The Geological Survey of India, 1846 to 1947, 889
Fox, E. N. : Technical Mathematics, *review*, 552
Fox, F. A. : Degree of D.Sc. of the University of Birmingham conferred on, 85
Fox, Prof. H. Munro : *Daphnia* Hæmoglobin, 431
Chlorocruorin and Hæmoglobin, 825
Føyn, E., and Hobaek, A. : Acid Production in Saliva/Cane-sugar Solutions, 758
Francis, Dr. G. E., and others : Use of Radioactive Isotopes in Immunological Investigations, 339
Frank, Dr. F. C. : Hypothetical Alternative Energy Sources for the 'Second Meson' Events, 525
Frankl, E. K. : The Experimental Study of Structures (Prof. A. J. S. Pippard), *review*, 349
Franklin, Dr. K. J. : Appointed to the University of London chair of physiology at St. Bartholomew's Hospital Medical College, 16, 599 ; work of, 599
Franklin, T. Bedford : Science and Reality, *review* by F. Ian G. Rawlins, 349
Franks, Sir Oliver : Central Planning in War and Peace, 1
Fraser, A. Stewart, and others : Mendelian Inheritance in New Zealand Romney Sheep, 646
Fraser, Dr. F. C. : Sound Emitted by Dolphins, 759
Fraser, G. K. (Forsyth, Dr. W. G. C., and) : Freezing as an Aid in the Drying and Purification of Humus and Allied Materials, 607
Fraser, Sir John : *Death* of, 821
Fraser, Dr. Russell : Appointed to the University of London readership in medicine at the British Postgraduate Medical School, 601
Freedman, —. : Atomic Energy and the Veto, 460
Freeman, J. A. : Pests of Stored Foods, 739
Freeman, S. M. : Rheology of Minerals, 845
Freney, Martin R. : Coiling of Wool Induced by certain Reagents, 799
Frenkel's Views on the Origin of Terrestrial Magnetism (Prof. Louis B. Slichter and Dr. E. C. Bullard), 157
Frey, Dr. E. R. : Biology and Juvenile Delinquency, 803
Friedländer, Carl (1847–87), 668
Frisch, Prof. O. R. : Honorary degree of D.Sc. of the University of Birmingham couferred on, 85
Liquid Helium and its Properties, 387
Peaceful Applications of Nuclear Fission, 452
Progress in Nuclear Physics, 493
Fritz, Sigmund, and others : Unit for Solar Radiation Work, 327
Frizzi, Dr. Guido : Salivary Gland Chromosomes of *Anopheles*, 226
Fröhlich, Dr. H. : Decay of Negative Mesons in Matter, 255
Liquid Helium and its Properties, 385
Frumkin, Prof. A. : Electrode Processes, 306
Fry, D. W. : Progress in Nuclear Physics, 494
Fry, D. W., and others : Travelling-Wave Linear Accelerator for Electrons, 351
Fuchs, Dr. K. : Liquid Helium and its Properties, 387
Fuel, Institute of : Melchett Medal for 1947 awarded to Major Kenneth Gordon, 360
Fulmer Research Institute (E. A. G. Liddiard), 165
Address at the Opening of the (Sir Stafford Cripps), 150
Fulton, Prof. Angus Robertson : Honorary degree of LL.D. of the University of St. Andrews conferred on, 324
Fulton, F., and Niven, J. S. F., and others : Chemotherapeutic and other Studies of Typhus, 726
Fulton, Dr. J. D., and Dunitz, Dr. J. D. : Constitution of the Irradiation Product from Stilbamidine, 161
Fundamental Research : Tata Institute of, 112
Fürth, Dr. R. : A Unified Theory of Spontaneous Electrical Fluctuations in Thermionic Valves, 832
Future : Special issue on Britain in 1955, 824

GABOR, Dr. D. : A Space-Charge Lens for the Focusing of Ion Beams, 89
Gaddum, Prof. J. H. : Appointed a member of the Medical Research Council, 293
The U.S. Pharmacopœia, *review*, 449
'Cushny's Pharmacology', *review*, 887
Gale, Dr. Ernest F. : Correlation between Penicillin Resistance and Assimilation Affinity in *Staphylococcus aureus*, 407
Gamage, Leslie : Appointed chief business adviser to the Minister of Civil Aviation, 185
Gardam, G. E. : Electrode Processes, 306
Garlick, G. F. J., and Gibson, A. F. : Decay of Luminescence due to Forbidden Optical Transitions, 303
Garner, Prof. F. H., and Nissan, Dr. Alfred H. : Rheological Behaviour and Classification, 329
Garner, Prof. W. E. : Electrode Processes, 306
Garnett, Dr. Maxwell : The Education of the Man of Science, 521
Garnham, Dr. P. C. C. : Mortality of *Aedes aegypti* Feeding on Rabbits receiving Oral 'Gammexane', 156
Appointed to the University of London readership in medical parasitology at the London School of Hygiene and Tropical Medicine, 185
Garratt, G. R. M. : Radio Reflexions from Meteoric Ionization, 76
Garrick, P. : Estimation of Potassium in Composts and Sewage Sludges, 434
Garrod, Prof. L. P. : The Story of Penicillin, *review*, 38
Garry, Prof. R. C. : Appointed to the regius chair of physiology in the University of Glasgow, 117 ; work of, 117
Gascoigne, R. K. J. : Appointed entomologist to the East African Anti-Locust Directorate, Kenya, 51
Gaskell, Walter Holbrook (1847–1914), 561
Gasser, Prof. H. S. : Honorary degree of D.Sc. of the University of Oxford conferred on, 152, 249
Gates, Prof. Reginald Ruggles : Human Genetics, *review* by Prof. F. A. E. Crew, 274
Gavin, L. D. M. : Degree of M.D. of the University of Aberdeen conferred on, 51
G.-B. Instructional, Ltd. : Film on Atomic Physics, 822
General Medical Council : Recommendations as to the Medical Curriculum, 481
Genetical Society of Great Britain : Election of honorary members, 83
Geodesy and Geophysics, International Union of (Dr. J. M. Stagg), 558
Geographical Society, Royal : Exhibition of Highways of the Air, 863
Geological Society of Turkey : Objects and activities of the, 16
Geological Survey of India, 1846 to 1947 (Sir Cyril S. Fox), 889
George, Dr. [illegible]. P., and Jason, A. C. : Observations Underground of Penetrating Cosmic Ray Showers, 327
George, Dr. P. : Reaction between Catalase and Hydrogen Peroxide, 41
German Hydrographic Institute, Hamburg : To issue the *German Hydrographic Journal*, 219
Annual Report of the, 705
German Physical Society in the British Zone : Autumn Conference of the (Prof. S. Tolansky), 723
Gernandt, Dr. Bo : Mechanism of Colour Vision, 664
Gerrard, Dr. W., and Lessing, W. : Optical Rotatory Power and Atomic Dimension, 467
Gesellschaft Deutscher Chemiker in der Britischen Zone : Second General Meeting, 428
Ghosh, A. K., and Bose, A. : Occurrence of Microflora in the Salt Pseudomorph Beds, Salt Range, Punjab, 796
Gibb, John : Sun-Bathing by Birds, 785
Gibson, A. F. (Garlick, G. F. J., and) : Decay of Luminescence due to Forbidden Optical Transitions, 303
Gibson, H. S. : Awarded the Redwood Medal of the Institute of Petroleum, 117

Gibson, W. M., and others : Photo-Disintegration of the Deuteron, 534
Gibson-Hill, C. A. : British Sea Birds, *review* by R. M. Lockley, 591
Gilbey, B. E. : A New Blood Group Antigen, 'Jobbins', 362
Gilles, Dr. John : Discovery of Chloroform Anæsthesia, 668
Gillis, Dr. J. : Relations between Structure-Factors, 866
Gittins, J. S. : Awarded a grant from the Leverhulme Research Fellowships, 119
Glaessner, Martin F. : Principles of Micropalæontology, *review* by Prof. B. Sahni, 771
Glees, Dr. P. : Osmophilic Granules in Chromatolytic Nerve Cells, 194
Glees, Dr. P., and others : An Ensheathed Rotating Knife for Causing Brain Lesions, 365
Glennan, Dr. T. K. : Appointed president of the Case Institute of Technology, 83 ; work of, 83
Glückauf, Dr. E. : Adsorption Isotherms from Chromatographic Measurements, 301
  Progress in Nuclear Physics, 494
Golberg, Dr. L., and De Meillon, Dr. B. : Further Observations on the Nutritional Requirements of the Larva of *Aedes aegypti* L., 582
Golberg, Dr. L., and others : Pteroylglutamic Acid in Liver Extracts and Urine, 22
Gold, T. (Pumphrey, Dr. R. J. ; and) : Transient Reception and the Degree of Resonance of the Human Ear, 124
Gold, V. : Electrode Processes, 306
Gold, Silver and Jewellery Industries, Design and Research Centre for the : First Annual Report, 863
Goldberg, Morris : English-Spanish Chemical and Medical Dictionary, *review*, 418
Golde, R. H. : Occurrence of Upward Streamers in Lightning Discharges, 395
Goldsmiths, Worshipful Company of : Gift of £6,000 to the Council for the Promotion of Field Studies for a residential field study and research centre at Malham Tarn House, 84
Good, Percy : Standardization in Industry, 618
Goodchild, A. J. P. : Appointed entomologist, Gold Coast, 745
Gooderham, W. J. : A New Apparatus for Gas Analysis by the Soap Film Method, 441
Goodeve, Sir Charles : Electrode Processes, 307
Goodstein, R. L. : Appointed professor of mathematics in University College, Leicester, 863
Goodwin, A. J. H. : The Loom of Prehistory, 393
Gordon, Major Kenneth : Awarded the Melchett Medal for 1947 of the Institute of Fuel, 360
  Hydrogenation in the Fuel and Chemical Industries (Melchett Lecture), 360
Gordon, Seton : A Naturalist's Notes, *review*, 693
Gorham, E. : Awarded an Overseas Science Research Scholarship for 1947 by the Royal Commissioners for the Exhibition of 1851, 119
Gorini, Dr. Luigi, and Torriani, Annamaria : Biochemistry of *Escherichia coli* and the Production of Penicillinase, 332, *errata*, 394
Gottschalk, Dr. A. : Mechanism of Enzyme Specificity in the Domain of Carbohydrates, 113
Gough, D. I. (Hales, A. L., and) : Blackett's Fundamental Theory of the Earth's Magnetic Field, 746
Gough, Dr. H. J. : Awarded the Medal of Freedom with Silver Palm by the Government of the United States, 513
Govaerts, Dr. J. : Urinary Excretion of Phosphate with $^{32}_{15}$P as Indicator, 53
Gracie, W. McAuley : Pests of Stored Foods, 739
Graddon, P., and others : A Semi-Quinonoid Oxidation Product of 4 : 4-Diethoxydinaphthyl, 187
Graetzer, H. : Appointed assistant lecturer in mathematics in the University of Sheffield, 564
Graham, Dr. Alastair : Title of professor of zoology in the University of London conferred on, 185
Grainger, Dr. John : Vegetables of Hong Kong, *review*, 658
Granér, Fredrik, and Sillén, Dr. Lars Gunnar : Hydrolysis of Bi³+. Oxygen Bridging—a New Type of Ionic Equilibrium, 715
Granit, Prof. Ragnar : Mechanism of Colour Vision, 664
  Visual Cells of the Guinea Pig, 838
Grant, F. : Appointed an under-secretary in the Ministry of Agriculture and Fisheries, 785
Grant, Dr. J. : Awarded a grant from the Leverhulme Research Fellowships, 119
  Modern Paper-Making (Robert Henderson Clapperton and William Henderson), third edition, *review*, 814
Grant, Miss M. W. : Nutrition in Newfoundland, 135
Grassland Society, British, and the British Society of Animal Production : Joint meeting on Grassland and Animal Production, 249
Graves, Prof. Lawrence M. : The Theory of Functions of Real Variables, *review* by T. M. M., 592
Gray, Prof. James : Retirement from membership of the Agricultural Research Council, 152
Gray, H. E. : Pests of Stored Foods, 739
Green, A. T. : Appointed honorary general secretary of the British Ceramic Society, 530
Green, F. Needham : Local Geology as affecting the Water Supply of Brighton, 343
Green, George (1793–1841), 561
Green, Prof. H. N. : Granted the additional title of director of cancer research in the University of Sheffield, 745
Green, H. S. : Liquid Helium and its Properties, 385
Green, L. L., and others : Photo-Disintegration of the Deuteron, 534
Greenbaum, A. L. (Folley, Dr. S. J., and) : Decrease in the Arginase of the Liver and Mammary Gland in Adrenalectomized Lactating Rats as compared with Pair-fed Controls, 364
Greenough, G. B. : Residual Lattice Strains in Plastically Deformed Metals, 258
Greenshields, Dr. F. : Bacteriology of Water, 583
Greenstein, Jesse P. : Biochemistry of Cancer, *review* by Prof. F. Dickens, 241
Greenwood, Prof. J. Neill, and Myers, R. H. : Annealing Temperature and Hardness of Tantalum, 675
Gregory, Prof. F. G., and Purvis, O. N. : Abnormal Flower Development in Barley Involving Sex Reversal, 227
Gregory, Joshua C. : Onslaught on a Superstition, *review*, 276
Greig, Prof. J. : Automatic Regulators and Servo Mechanisms, 340
Grew, K. E. W. (Bowden, Dr. F. P., and) : Electrode Processes, 306
Grier, Lynda : The Evolution of Secondary Education in Britain, 289
Griesbach, W. E., and others : Relative Activities of *l*- and *dl*-Thyroxine 192
Griffin and Tatlock, Ltd. : Catalogue of Laboratory Equipment, 635
Griffiths, Dr. J. Howard : *Obituary* of Prof. T. David Jones, 527
Griffiths, Dr. J. H. E. (Bagguley, D. M. S., and) : Paramagnetic Resonance and Magnetic Energy Levels in Chrome Alum, 532
Griffiths, Mervyn : Effects of Anterior Pituitary Extract and Hypophysectomy on Blood-Sugar Levels after Injection of Alloxan, 758
Griffiths, Sir William : Appointed a member of the Advisory Council for Scientific and Industrial Research, 530
Griffiths, W. V. : Agricultural Products and the Chemical Industry, 373
Grimley, T. B., and Mott, Prof. N. F. : Electrode Processes, 306
Griswold, Prof. John : Fuels, Combustion and Furnaces, *review* by H. J. Hodsman, 5
Grivet, Prof. P. : Progress in Electron Microscopy, 763
Groendijk, H. (Vries, Dr. Hl. de, and) : Evidence against Spontaneous Emission of Neutrons by Uranium X, 435

Horner, R. G., and Purslow, E. T. : Dependence of Anomaloscope Matching on Viewing Distance of Field Size, 23
Horology and Instrument Technology : National College of, 324
Horváth, J., and Krámli, A. : Microbiological Oxidation of Cholesterol with *Azotobacter*, 639
Horváth, Stephan (Ivánovics, Prof. George, and) : Raphanin, an Antibacterial Principle of the Radish (*Raphanus sativus*), 297
Hothersall, A. W. : Electrode Processes, 306
Houssay, Prof. B. A. : Honorary degree of D.Sc. of the University of Oxford conferred on, 152, 249
Awarded one half of the Nobel Prize for Physiology and Medicine for 1947, 599 ; work of, 599
Howard, Sir Albert : *Death* of, 561 ; *obituary* by Sir John Russell, 741
Howarth, Dr. W. O. : Crude Drugs and other Raw Materials of Vegetable and Animal Origin, *review*, 4
Howell, W. N., and others : Anode Phenomena in Molten Electrolytes, 504

Hoyer, Prof. Henryk : *Death* of, 667
Hoyle, F. : Chemical Composition of the Stars, 744
Hu, Tsi-Ming (Massey, Prof. H. S. W., and) : Nuclear Forces and the Magnetic Moment of the Deuteron, 794
Hudlicky, Dr. Milos : Awarded a U.N.E.S.C.O. Fellowship, 706
Hudson, P. S. : At the Plant Breeders' conference at Cambridge, 425
Hughes, Prof. A. L. : *Obituary* of Prof. G. E. M. Jauncey, 116
Hughes, Prof. E. D., and others : Text-book Organic Chemistry, 406
  *neo*Pentyl Alcohol and Steric Hindrance, 901
Hughes, G. K., and others : A New Source of Taraxerol, 577
Hughes, Dr. L. E. C. : Photoelectric Cells (Dr. A. Sommer), *review*, 854
Hulm, J. K. : Dielectric Properties of Single Crystals of Barium Titanate, 127
Hulse, C. : Appointed lecturer in fuel technology in the University of Sheffield, 85
Hulubei, H. (Cauchois, Y., et) : Tables de constantes et données numériques, I, Constantes sélectionées, longueurs d'onde des émissions X et des discontinuités d'absorption X, *review* by Dr. H. Lipson, 626
Hume-Rothery, Dr. W. : Appointed honorary lecturer in the Department of Metallurgy in the University of Sheffield, 745
Hungarian Academy of Sciences : Publication of new scientific periodicals, 745
Hunter, Dr. C. L. F. : Appointed director of the Bray Research Station by PAL Chemicals, Ltd., 152
Hunter, Dr. T. G. : Appointed professor of chemical engineering in the University of Sydney, 85
Huntington, Dr. Ellsworth : *Death* of, 561 ; *obituary* by Dr. C. E. P. Brooks, 666
Hurley, T. F. : Pulverized Fuel, 318
Hurst, Dr. C. C. : *Death* of, 896
Hurst, Dr. H. E., and others : The Nile Basin, Vol. 7, The Future Conservation of the Nile, 215
  A Long-Term Plan for the Nile Basin, 611
Hustich, Dr. I. : Climatic Fluctuations and Vegetation Growth in Northern Finland during 1890–1939, 478
Hutchinson, Dr. Irene : Bacteriology in the Kitchen, 50
Hutton (James), Geologist and Agriculturist (Royal Society of Edinburgh meeting in commemoration of the hundred and fiftieth anniversary of the death of), 727
Hutton (James), 1726–97, and Sir Charles Lyell, 1797–1875 (V. A. Eyles), 694
Hutton, Prof. J. H. : Peoples of the Indian Archipelago, *review*, 732
Hutton, Prof. R. S. : Publication and Classification of Scientific Knowledge, 649
Huus, T., and others : Gamma-Ray Yield Curves of Separated Neon Isotopes Bombarded with Protons, 498
Huxley, Aldous : Science, Liberty and Peace, 172 ; *review* by R. Brightman, 733
Huxley Committee on the Conservation of Nature in England and Wales : Report of the, 809
Hydraulic Research Organisation : Appointment of Sir Claude Inglis as director, 149
Hydrobiologica et Protistologica Acta : Publication of a new international review, 824
Hydrographic Institute, German : To issue the *German Hydrographic Journal*, 219
  Annual Report of the, 705

ILEY, R., and Riley, Prof. H. L. : Preparation of Colourless Carborundum, 468
Illuminating Engineering Society : Appointment of G. F. Cole as secretary, 51
Imms, Dr. A. D. : Recent Research on Locusts, 67
Imperial Agricultural Bureaux : Joint Publication No. 10, The Use and Misuse of Shrubs and Trees as Fodder, 862
  Name changed to Commonwealth Agricultural Bureaux, 824
Imperial Bureau of Animal Health : Meeting on D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in South Africa, 485
Imperial Bureau of Pastures and Forage Crops : Name changed to Imperial Bureau of Pastures and Field Crops, 85
Imperial Chemical Industries, Ltd. : Retirement of J. Baddiley as director of research, 528
Imperial College of Science and Technology : Appointment of Dr. Margaret Fishenden to the University of London readership in applied heat, 16
  Title of University of London reader in civil engineering conferred on Dr. S. R. Sparkes, 185
  Title of University of London reader in mining geology conferred on Dr. David Williams, 462
  Title of professor emeritus of mining geology in the University of London conferred on Prof. W. R. Jones, 601
Indian Archives, No. 1, 292
Indian Anthropological Institute, Journal of the, Vol. I (New Series), 669
Indian Association for the Cultivation of Science : Annual Report for 1946, 784
Indian Institute of Science, Bangalore : Appointment of Dr. B. P. Dey as director, 745
Industrial Property, International Association for the Protection of : Congress of the, 442
Industrial and Engineering Chemistry : Special number on the Chemistry of Fluorine and its Compounds, 462
Information : Publication of the first issue (Association of Special Libraries and Information Services), 897
Inglis, Sir Claude : Effect of Charge in Turbulent Flow in Alluvium, 60
  Appointed director of the Hydraulic Research Organisation, 149 ; work of, 149
Ingold, Prof. C. K., and others : Text-book Organic Chemistry, 406
  *neo*Pentyl Alcohol and Steric Hindrance, 901
Institutum Divi Thomæ : Gift from the Donner Foundation, Inc., of a building for scientific research, 118
Instrument Technology : National College of Horology and, 324
Interdepartmental Scientific Panel : Work of the, 392
International Association for the Protection of Industrial Property : Congress of the, 442
International Bureau of Physico-Chemical Standards : To establish a collection of pure chemical substances, 822
International Council of Scientific Unions : Annual Meeting of the Executive Committee, 218
  Reports of Proceedings of the Fourth General Assembly, 218
  First post-war meeting of the Committee on Science and its Social Relations, 742
International Institute for Amazonian Studies : A Projected, 427
International Meteorological Organisation : Meetings in Toronto and Washington of the, 817
International Organisation for Standardisation : First meeting of the Council, 389
International Scientific Film Association : Formation of an, 601
International Society for Cell Biology : Foundation of the, 784
  Election of Prof. J. Runnström as president, 784
International Understanding, British Society for : Teacher's Guide to the United Nations Organisation, 529
International Union of Biological Sciences : First post-war meeting, 462
  Election of officers, 462
  Symposium on the Role of Trace Elements in Plant Physiology, 564
International Union of Chemistry : Meetings of the, 14
International Union of Crystallography : Formation of [redacted] 83
International Union of Family Organisations (Cyri[redacted]y), 183
International Union of Geodesy and Geophysics (Dr. J. M. Stagg), 558
International Wool Secretariat : Appointment of P. A. Wells as director of education, 428
Ipatieff, Vladimir N. : The Life of a Chemist—Memoirs of, edited by Xenia Joukoff Eudin, Helen Dwight Fisher and Harold H. Fisher, translated by Vladimir Haensel and Mrs. Ralph H. Lusher (Prof. D. M. Newitt), 43
Irish Chemical Association : Election of officers, 497
Irish Chemical Association and the Dublin Section of the Royal Institute of Chemistry : Colloquium on the Industrial Utilization of Agricultural Products and of Seaweed, 373
Iron and Steel Research Association, British : Opening of Sketty Hall Laboratories, 100
  Activities of the, 233
  New Physics Laboratories opened by Lord Rayleigh, 530, 684
Irvine, Dr. F. R. : Awarded a grant from the Leverhulme Research Fellowships, 119
Irvine, Sir James : The Education of the Man of Science, 521
Italian Association for the Progress of Zootechny : Establishment at Milan, 785
Italian National Council of Research : International Congress to marks the occasion of the Marconi Jubilee, 743
Ivanoff, —. : Mechanism of Colour Vision, 666
Ivánovics, Prof. George, and Horváth, Stephan : Raphanin, an Antibacterial Principle of the Radish (*Raphanus sativus*), 297
Iyer, P. V. Krishna : Random Association of Points on a Lattice, 714
Izzo, Prof. R. A., and Cicardo, V. H. : Gonads and Experimental Tuberculosis, 155

JACKSON, Dr. D. A. : Structure of Spectral Lines, *review*, 244, 909
Jackson, Dr. L. C. : Liquid Helium and its Properties, 386
Jaeger, J. C. (Carslaw, Prof. H. S., and) : Conduction of Heat in Solids, *review* by Prof. L. Rosenhead, 886
James, Dr. Eric : The Education of the Man of Science, 520
James, H. E. O. : Appointed to the University readership in psychology at the University of London Institute of Education, 16
Jamieson, J. R. (Jones, R. Norman, and) : Fluorescent Constituents of Liver Lipid Extracts, 677
Jancsó, Dr. Miklós : Histamine as a Physiological Activator of the Reticulo-Endothelial System, 227
Jarratt, Sir William : Patents and the National Economy, *review*, 482
Jason, A. C. (George, Dr. E. P., and) : Observations Underground of Penetrating Cosmic Ray Showers, 327
Jauncey, Prof. G. E. M. : *Obituary* by Prof. A. L. Hughes, 116
Jayewickreme, Dr. S. H., and Niles, W. J. : Rearing of *Trombicula acuscutellaris* Walch, 578
Jeffrey, Dr. G. A. : X-Ray Crystallographers in Industry, 29
Jeffreys, Prof. H. : Publication and Classification of Scientific Knowledge, 649
  Rheology of Minerals, 844
Jeffreys, Prof. H., and Jeffreys, Dr. Bertha Swirles : Methods of Mathematical Physics, *review*, 139
Jenkin, T. J. : At the Plant Breeders' conference at Cambridge, 425
Jenkins, J. D.: Appointed lecturer in mining in the University of Leeds, 563
Jenkins, Dr. S. H. (Southgate, Dr. B. A., and) : Pollution by Trade Wastes from Food Industries, 200
Jensen, Dr. H. L. : Appointed chief of the Division of Bacteriology of the State Laboratory of Plant Culture in the Danish Ministry of Agriculture, 16
Jepson, W. F. : Economic Control of the Relapsing Fever Tick in African Houses, 874
Jerslev, Miss Bodil : Crystal Structure of Hydroxylammonium Chloride and Bromide, 641
Jewett, Frank B., and others : Science in Progress, edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
John, Dr. D. Dilwyn : *Obituary* of Dr. H. L. Clark, 391
Johnson, A., and Johnson, L. G. : Appointed lecturers in the Departments of Economics and Extra-Mural Studies in the University of Leeds, 563
Johnson, R., and Smithson, Dr. F. : A Sedimentation Phenomenon, 26
Johnston, D. : Appointed lecturer in metallurgy in the University of Leeds, 745
Joliot, Prof. J. F. : Awarded the Hughes Medal for 1947 of the Royal Society, 704, 841
Jollans, J. L. : Appointed agricultural officer, Gold Coast, 745
Jones, A. Vallance (Sutherland, Dr. G. B. B. M., and) : Use of Polarized Radiation in Infra-Red Analysis, 567
Jones, Creech : Government proposal to establish a Colonial Development Corporation, 171

Jones, D. J. : Methods of Crack Detection, 557
Jones, Dr. E. T. : British Needs and Resources of Calories, Protein and Calcium, 701
Jones, E. W. : Climatic Fluctuations and Vegetation Growth in Northern Finland during 1890–1939, 479
Jones, Prof. F. Llewellyn : Physics of Electric Contacts, *review*, 417
Jones, Prof. H. : Liquid Helium and its Properties, 387
Jones, Lieut.-Colonel H. F. : Awarded the Bronze Star Medal by the Government of the United States, 513
Jones, Sir Harold Spencer : John Couch Adams and the Discovery of Neptune, 324
Elected president of the Institute of Navigation, 427
Jones, I. Chester : A Tri-colour (Mosaic) Shorthorn Cow, 337
Jones, Dr. J. K. N. : Degree of D.Sc. of the University of Birmingham conferred on, 85
Jones, Dr. J. K. N., and others : Quantitative Estimation of Mixtures of Sugars by the Paper Chromatogram Method, 86
Structure of Starch—Mode of Attachment of the Side-chains in Amylopectin, 899
Jones, Prof. Ll. Rodwell : *Obituary*, 459
Jones, R. Norman, and Jamieson, J. R. : Fluorescent Constituents of Liver Lipid Extracts, 677
Jones, Miss R. P. : Effect of Thiourea on the Endostyle of Ammocœtes, 638
Jones, Dr. R. V. : Awarded the Medal for Merit by the Government of the United States, 513
Jones, Prof. T. David : *Obituary* by Dr. J. Howard Griffiths, 527
Jones, T. J. : Thermionic Emission from Oxide-Coated Cathodes, 726
Jones, Prof. W. R. : Title of professor emeritus of mining geology in the University of London conferred on, 601
Jordan, Dr. L. A. : Reduction of Fire Risks in Ships, 216
The Paint Research Association, 629
Jørgensen, C. Barker : Influence of Adenohypophysectomy on the Transfer of Salt across the Frog Skin, 872
Josephy, E., and Radt, F. (edited by) : Elsevier's Encyclopædia of Organic Chemistry, Vol. 14, Tetracyclic and Higher-Cyclic Compounds, Series 3, Carboisocyclic Condensed Compounds, *review*, 626
Jowett, G. H. : Appointed assistant lecturer in statistics in the Department of Mathematics in the University of Sheffield, 564
Judd, Prof. C. H. : Mechanism of Colour Vision, 666
Juni, E., and others : Physiological Heterogeneity of Metaphosphate in Yeast, 717

Mann, Dr. T. (Davies, Dr. D. V., and) : Functional Development of Accessory Glands and Spermatogenesis, 295
Manneback, C., and others : Interaction Terms in Molecular Vibrations, 793
Mansfield, W. S. (compiled and commented upon by) : The Farmer's Friend, or Wise Saws and Modern Instances, *review* by Prof. John Read, 140
Manton, Prof. I. : Ecology of Norway, *review*, 4
Maple, Dr. W. Norman : The Dinosaurs, 343
Marchionna, Frederick : Butalastic Polymers, *review* by Prof. H. W. Melville, 851
Marconi Company : Souvenir Brochure to mark the fiftieth anniversary of the foundation of the, 743
Mardles, Dr. E. W. J. : The Chemistry and Rheology of Clay, 511
  Rheology of Minerals, 844, 845
Marine Biological Association, Scottish : Annual Report for the Year 1945–46, [illegible]
Marley, W. G. : Peaceful Applications of Nuclear Fission, 452
Maron, Prof. Samuel H. (Prutton, Prof. Carl F., and) : Fundamental Principles of Physical Chemistry, *review* by Dr. J. A. V. Butler, 592
Marquis, Prof. Donald C. : Psychology of Social Change, 622
Marrack, Prof. J. R. : British Needs and Resources of Calories, Protein and Calcium, 701
Marriage, A. : Transformation of Trichromatic Distribution Curves, 197
Marriage Hygiene : First number of a New Series, 823
Mars, J. : Appointed lecturer in economics in the University of Leeds, 745
Marshall, A. J. : Elected to a Beit Memorial Junior Fellowship for Medical Research, 152
Marshall, Dr. James : Atlas of Bacteriology (Dr. R. Cranston Low and T. C. Dodds), *review*, 349
  Charles-Édouard Brown-Séquard, *review*, 383
  Précis de dermatologie (J. Darier, A. Civatte et A. Tzanck), cinquième édition par A. Civatte, *review*, 592
Marshall, Dr. P. B. : Mode of Action of 'Paludrine', 463
Martin, E. F. : Appointed deputy director of agriculture, Kenya, 745
Martin, George C. : 'DD' as a means of Controlling *Heterodera rostochiensis*, (Woll.), 720
Martin, Kingsley : The Press the Public Wants, 413
Martin, V. C. (Fisher, Prof. R. A., and) : Spontaneous Occurrence in *Lythrum salicaria* of Plants Duplex for the Short-style Gene, 541
Martin, W. J. : Degree of D.Sc. of the University of London conferred on, 16
Martin, W. S. : Degree of D.Sc. of the University of London conferred on, 601
Martinovitch, Dr. Petar N. : State Laboratory for Experimental Biology and Medicine, Novi Sad, Yugoslavia, 476
Martyn, Dr. D. F. : Location of the Currents causing the Solar and Lunar Diurnal Magnetic Variations, 535
Maskery, A. : Methods of Crack Detection, 557
Massé, Pierre : Avenir aléatoire, *review* by Charles F. Carter, 383
  Les réserves et la régulation de l'avenir dans la vie économique, I, Avenir déterminé, *review* by Charles F. Carter, 383
Mason, B. J. : Awarded a Shirley Fellowship by the British Cotton Industry Research Association, 428
Massey, Prof. H. S. W., and Hu, Tsi-Ming : Nuclear Forces and the Magnetic Moment of the Deuteron, 794
Masters, David : Miracle Drug, the Inner History of Penicillin, *review* by Prof. L. P. Garrod, 38
Matthai, Prof. G. : *Obituary* by Dr. R. B. Seymour Sewell, 116
Maulik, Dr. S. : Introduction of a Beetle from Trinidad into Mauritius to Control *l'herbe Conde* (*Cordia macrostachya*), 194
  Willow as Host-Plant of *Crioceris merdigera*, 609
Maw, G. A. : Identification of Creatine by Partition Chromatography, 261
Maxwell, W. H. : Current Waterworks Practice, *review* by B. C., 775
Mayer-Gross, W., and Walker, J. W. : Effect of *l*(+) Glutamic Acid in Hypoglycæmia, 334
Maynard, Prof. Leonard A. : Animal Nutrition, second edition, *review* by Dr. D. P. Cuthbertson, 854
Mayné, Prof. R. : Pests of Stored Foods, 739
Meadows, G. W., and others : Polymerization of Olefins by Friedel-Crafts Catalysts, 869
Mechanical Engineering Research Station : To be established in Scotland by the Department of Scientific and Industrial Research, 562
Medawar, Prof. P. B. : Appointed to the chair of zoology in the University of Birmingham, 14 ; work of, 14
  Series of lectures at the International School in Social Biology, 803
Medawar, Prof. P. B. (Billingham, R. E., and) : Role of Dendritic Cells in the Infective Colour Transformation of Guinea Pig's Skin, 61
Medical Bookman and Historian : Publication of the first issue, 784
Medical Research Council : Appointment of Prof. N. Hamilton Fairley and Prof. J. H. Gaddum as members, 293
  Establishment of a new Toxicology Research Unit, 634
  Reconstitution of the Dental Research Committee, 824
Medicine, Royal Society of : Gold Medals awarded to Sir Alexander Fleming and Sir Howard Florey, 51
Medley, J. A. (King, G., and) : Effect of Polar Vapours on the Direct-Current Conductance of Keratin and Nylon, 438
Meek, Prof. J. M. : The Spark Discharge, 110
Megaw, Dr. H. D. : New Industrial Techniques and Results of X-Ray Crystallography, 30
Megaw, Sir John : Over-population as a World Problem, 783
Meijering, —. : Mechanical Properties of Metals, 696
Meinesz, Prof. Felix Andries : Awarded the Agassiz Medal for 1947 of the Murray Fund of the U.S. National Academy of Sciences, 169
Meinhardt, Peter : Inventions, Patents and Monopoly, *review* by Sir William Jarratt, 482
Meissel, Dr. M. N. : Hyper- and Avitaminosis in Micro-organisms, 269
Meksyn, Dr. D. : Relativity of Accelerated Motion, 834
Mellanby, Sir Edward : Awarded the Buchanan Medal for 1947 of the Roya Society, 704, 840
Mellink, Dr. J. H. : Liquid Helium and its Properties, 385
Mellon Institute : Annual Report for 1946–47, 651
Melville, Prof. H. W. : Quantitative Aspects of Free Radical Chemistry, 778
  Synthetic Rubber, *review*, 851
Mendelsohn, Dr. H. : A New Locality for *Cyprinodon dispar* Rueppel, 123
Mendelssohn, Dr. K. : What is Atomic Energy ?, *review* by Prof. P. B. Moon, 315
  Liquid Helium and its Properties, 385
Mendelssohn, Dr. K. (Brown, J. B., and) : A New Technique for Studying the Helium Film, 670
Menzies, J. W. : The Migrations of Salmon in the Sea, 33
Mercer, K. A. (Eastwood, Dr. E., and) : Radio Reflexions from Meteoric Ionization, 75
Metal Powder Report : Now issued at an annual subscription, 705
Metals, Institute of : May Lecture (Sir Wallace Akers), 182
Meteorological Organisation, International : Meetings in Toronto and Washington of the, 817
Metropolitan-Vickers Electrical Co., Ltd. : Appointment of Dr. C. Dannatt as chief electrical engineer, 150
  Gas-Turbine Propulsion in a Naval Vessel, 392
Meyer, Herta : Cultivation of the Erythrocytic Form of *Plasmodium gallinaceum* in Tissue Cultures of Embryonic Chicken Brain, 155
Meyer, Prof. Kurt H., and others : Structure of Amylopectin, 900
Miall, Dr. Stephen : *Death* of, 528
Michael, Dr. S. E. : Penicillin and other Antibiotics, 556
Michaelis, L., and others : Science in Progress, edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
Michelmore, A. P. G. : The Habits and Control of the Red Locust in Outbreak Areas and Elsewhere, 67
Microtecnic, Vol. I, No. 2 (April 1947), 496
Middlesex Hospital Medical School : Appointment of Dr. F. R. Selbie to the University of London readership in bacteriology, 185
  Appointment of Dr. David Slome to the University of London readership in physiology, 326
  Appointment of Dr. E. W. Balls to the University of London readership in anatomy, 326
Middleton, Dr. D. S. : Discovery of Chloroform Anæsthesia, 668
Military College of Science : Appointment by the War Office of an Advisory Council for the, 48
Millard, A. : Progress in Electron Microscopy, 763
Millard, Prof. E. B. : Physical Chemistry for Colleges, sixth edition, *review* by Dr. J. A. V. Butler, 592
Millen, William P., and others : Unit for Solar Radiation Work, 327
Miller, Genevieve (edited by) : William Beaumont's Formative Years, Two Early Notebooks, 1811–1821, *review* by Dr. E. Ashworth Underwood, 38

O'Reilly, H. L. : The Utilization of Carbohydrates, 373
O'Rourke, L., and others : Antitubercular Activity of Diphenyl Ethers and related Compounds, 800
Orr, Sir John Boyd : Pests of Stored Foods, 739
Orowan, Dr. E. : Publication and Classification of Scientific Knowledge, 649
    Mechanical Properties of Metals, 696
Osgood, Dr. Wilfred H. : *Death* of, 116
Osmond, Dr. D. A. : Problems of Soil and Land Classification, 687
O'Sullivan, G. F. : The Industrial Utilization of Agricultural Products and of Seaweed, 373
Overell, B. T. (Lugg, J. W. H., and) : Partition Chromatography of Organic Acids on a Paper Sheet Support, 87
Owen, Dr. E. C. : Nutrition and Symbiosis, 78
    British Needs and Resources of Calories, Protein and Calcium, 701
Oxford University Observatory : Retirement of Miss E. F. Bellamy from seismological work, 220
Oxley, T. A. : Pests of Stored Foods, 739

Pacific Science : New journal published by the University of Hawaii, 254
Pady, Prof. S. M., and others : Arctic Aerobiology, 876
Paint Research Association (Dr. L. A. Jordan), 629
  Twenty-first Anniversary of the, 293
Pal, Dr. Rajindar : Marking Mosquitoes with Fluorescent Compounds and Watching them by Ultra-violet Light, 298
PAL Chemicals, Ltd. : Appointment of Dr. C. L. F. Hunter as director of the Bray Research Station, 152
Palasi, V. Villar : A New Colour Reaction for the D Vitamins, 88
Palmer, Richard : School Broadcasting in Britain, *review*, 774
Paneth, Prof. F. A. : The Name of Element 23, 164
Papin, Denis : Tercentenary of (Dr. H. W. Dickinson), 422
Parcq, Lord du : Appointed a Trustee of the Beit Memorial Fellowships, 152
Paris, Dr. E. Talbot : Awarded the Medal of Freedom with Bronze Palm by the Government of the United States, 291, 513
Paris Academy of Sciences : Election of Pierre Teilhard de Chardin, Gaston Delépine and Prof. Pierre Pruvost as *correspondants* for the Section of Mineralogy, 51
  Election of Prof. H. A. Kramers and Prof. René de Mallemann as *correspondants* for the Section of General Physics, 51
  Election of Prof. Emile Briner, Dr. C. H. Desch and Prof. Hans von Euler as *correspondants* for the Section of Chemistry, 51
  Election of Prof. G. H. Hardy and Dr. A. F. Blakeslee as foreign associates, 85
  Election of Prof. Gustave Ribaud as a member of the Section of General Physics, 152
  Election of Prof. Hermann Weyl and Prof. George Polya as *correspondants* for the Section of Geometry, 326
Parker, Dr. A. : *Obituary* of Dr. H. T. Calvert, 597
Parkinson, Dr. John : *Death* of, 116 ; *obituary* by Dr. W. E. Swinton, 390
Parson, Alfred Lauck : The Matter-Radiation Cycle in the Cosmos (and the Second 'Law')—the Sun's Equilibrium, 906
Parsons, Sir John : Mechanism of Colour Vision, 666
Parsons, Roger (Bockris, Dr. J. O'M., and) : Mercury Tube Effect, 232
Parsons, S. J., and others : Solar and Terrestrial Radio Disturbances, 371
Parsons, Ursula (Mann, Dr. T., and) : Effect of Testicular Hormone on the Formation of Seminal Fructose, 294
Parsons and Co., Ltd., C. A. : Publication No. 15, Grubb, Parsons and Co.'s Infra-red Gas Analyser, 220
Partington, Prof, J. R., and others : Dielectric Residual Effects in Titanates, 877
Partridge, J. H. : Degree of D.Sc. of the University of Birmingham conferred on, 85
Partridge, S. M., and others : Displacement Chromatography on Cation-Exchange Materials, 374
Pascal, Prof. R. : The Expansion of the Universities, 522
Pasquill, F. : Atmospheric Turbulence, 860
Passey, Prof. R. D., and others : Electron Microscope Studies of Normal and Malignant Tissues of High- and Low-Breast-Cancer Strains of Mice, 565
  Progress in Electron Microscopy, 763
Pastures and Forage Crops, Imperial Bureau of : Name changed to Imperial Bureau of Pastures and Field Crops, 85
Paterson, Sir Clifford : Elected chairman of the General Council of the British Standards Institution, 16
  The Electron Liberated, 358, 776
Paterson, Dr. J. H. : Appointed vice-president of the Institute of Welding, 16
Paterson, Stewart (Mitchell, Dugald, and) : Spread of Detonation in High Explosives, 438
Pauli, Wolfgang : Meson Theory of Nuclear Forces, *review* by Prof. Max Born, 418
Pauling, Prof. Linus C.: Appointed George Eastman visiting professor in the University of Oxford, 16
  Honorary degree of the University of London conferred on, 85
  Awarded the Davy Medal for 1947 of the Royal Society, 704, 840
Pavliček, Prof. F. : *Obituary* by Dr. J. G. F. Druce, 13
Payne, B. O. (Taylor, E. Wilfred, and) : A Variable Phase-Contrast System for Microscopy, 338
Payne, Santosh Kumar (Sen Gupta, Prof. J. C., and) : Leaf Heteromorphism and Photo-periods in *Sesamum orientale* L., 510
Payne-Scott, Ruby, and others : Relative Times of Arrival of Bursts of Solar Noise on Different Radio Frequencies, 256
Peacock, Dr. D. H. : Appointed lecturer in chemistry in the University of Sheffield, 85
Pearce, A. A., and others : Detection of Acetic Acid in *A. niger* Growing on a Glucose Medium, 573
Pearce, J. H. : Functions of a Complex Variable (Prof. Thomas M. Macrobert), third edition, *review*, 626
Pearce, Sir Leonard : *Death* of, 667
Pearsall, Prof. W. H. : Water Supply and Biology, 176
  Appointed editor of the *Annals of Botany*, 861
Pearce, Dr. R. W. B., and Sinha, S. P. : Absorption Bands of Li_2, Na_2, K_2 and NaK, 159
Peczenik, Dr. O. : The Vienna Academy of Sciences, 406
Peczenik, Dr. O., and Zei, M. : Influence of Hypophyseal Hormone and of Nervous Impulses on the Colour-dress of Hermaphrodite Teleostean Fish, 788
Peierls, Prof. R. E. : Liquid Helium and its Properties, 387
  Atomic Energy and the Veto, 460
  Fundamental Physical Theory, 627
  At the Jubilee Celebrations of the Discovery of the Electron, 776
Peierls, Prof. R. E. (Ferretti, B., and) : Radiation Damping Theory and the Propagation of Light, 531
Peiser, H. S. : New Industrial Techniques and Results of X-Ray Crystallography, 31
Pelc, Dr. S. R. : Autoradiograph Technique, 749
Pell-Walpole, W. T. : Degree of D.Sc. of the University of Birmingham conferred on, 85
Pelzer, Dr. H. : Absolute Values of the Rates of Unimolecular Reactions, 576
Peng, Dr. W. H. (Morette, Cécile, and) : Cross-Sections for Production of Artificial Mesons, 59
Penn, H. S., and Kaplan, Prof. Joseph : Fluorescense of Cancerous and Non-Cancerous Lipoids, 18
Percival, Dr. E. G. V. : Modern Carbohydrate Chemistry, *review*, 208

Reid, J. M. (Curran, Dr. S. C., and) : Primary Ionization of β-Particles in Alcohol Vapour and Argon, 866
Reid, Prof. L. A. : Appointed to the University of London chair of philosophy of education at the University of London Institute of Education, 326
Rendle, Theodore (edited by Bacharach, A. L., and) : The Nation's Food, *review* by Dr. Leslie J. Harris, 242
Renner, Prof. Otto : Elected an honorary member of the Genetical Society of Great Britain, 83
Rennie, J. Basil, and others : Utilization of Citric Acid by some So-called Citrate-non-Utilizing Bacteria, 573
Research : Publication of the first number, 496
Revilliod, Dr. H. : Some Ways of Facing Social Evils in Switzerland, 803
Rewell, Dr. R. E., and Ainsworth, Dr. G. C. : Occurrence of *Aspergillus fumigatus* Fresen. in the Lung of an American Bison, 362
Reyne, Dr. A. : On the Structure of the Shells and Pearls of *Tridacna squamosa* Lam. and *Hippopus hippopus* (Linn.), 653
Reynoldson, Dr. T. B. : Urceolarian Epizoites of Flatworms, 265
Rheologists' Club, British : Annual Conference of the, 844
Rheologists' Club, British, and the South-Western Branch of the Chemical Society : Discussion on the Chemistry and Rheology of Clay, 511
Rhind, D. : Record of an African Fodder Grass from Central Burma, 195
Rhoderick, E. H. : Definition of Nuclear Quadrupole Moments, 255
Rhodes, A., and Templeman, Dr. W. G. : Effect of 4-Chloro-2-Methyl Phenoxyacetic Acid on the Mineral Content and Growth of Plants, 825
Rhodes, R. G. (Kay, H. F., and) : Barium Titanate Crystals, 126
Ribaud, Prof. Gustave : Elected a member of the Section of General Physics of the Paris Academy of Sciences, 152
Ribchester, —. : Absorption of Ultrasonic Waves in Liquids, 914
Richards, Alfred N. : Elected president of the U.S. National Academy of Sciences, 168
Richards, Dr. T. Ll. : New Industrial Techniques and Results of X-Ray Crystallography, 30
Richards, Dr. William J. : Awarded the Medal of Freedom with Bronze Palm by the Government of the United States, 513

Richardson, Dr. E. G. : Physical Science in Art and Industry, second edition, *review* by F. Ian G. Rawlins, 315
  Musical Acoustics, 765
  Absorption of Ultrasonic Waves in Liquids, 913
Richardson, Dr. H. O. W. : Progress in Nuclear Physics, 493
Richens, R. H. : Publication and Classification of Scientific Knowledge, 649
Richer, G. C. : Probabilities of Magnetization, 256
Riddiford, L. : Awarded an Overseas Science Research Scholarship for 1947 by the Royal Commissioners for the Exhibition of 1851, 119
Rideal, Prof. E. K. : The Work of the Royal Institution in Physical Chemistry in Great Britain, 245
Riet Lowe, Dr. van : Archæological Research in South Africa, 394
Rigby, Edward (1747–1821), 897
Rikli, Prof. Dr. M. : Das Pflanzenkleid der Mittelmeerländer, *review*, 416
Riley, Dr. D. P. : Publication and Classification of Scientific Knowledge, 649
Riley, Douglas W. : Appointed assistant lecturer in chemistry in the University of Sheffield, 564
Riley, Prof. H. L. (Iley, R., and) : Preparation of Colourless Carborundum, 468
Rimington, Prof. C. : *Obituary* of Sir F. Gowland Hopkins, 47
  Degree of D.Sc. of the University of London conferred on, 601
Ritchie, Prof. A. D. : American Philosophy, *review*, 37
Ritchie, Dr. E. G. : Appointed director of engineering laboratories of the British Coal Utilization Research Association, 706
Rivlin, R. S. : Hydrodynamics of Non-Newtonian Fluids, 611
Road Research Laboratory : Soils, Concrete and Bituminous Materials, a Record of a Course dealing with Airfield Construction, *review*, 518
Robb-Smith, Dr. A. H. T. : Notes on the Morphology of Infection by the Vole Acid-Fast Bacillus, 687
Roberts, Dr. Irene S. (Neuberg, Prof. Carl, and) : Invertase, *review*, 279
Robertson, Prof. J. Monteath (Abrahams, S. C., and) : Crystal Structures of *para*-Dinitrobenzene and *para*-Nitraniline, 569
Robinson, Prof. G. W. : Problems of Soil and Land Classification, 686
Robinson, J. T. (Broom, Dr. R., and) : Jaw of the Male Sterkfontein Ape-man, 153
  Further Remains of the Sterkfontein Ape-man, *Plesianthropus*, 430
Robinson, Sir Robert : Honorary degree of LL.D. of the University of Glasgow conferred on, 14
  Formulæ for Ethylene Oxide and Cyclopropane, 162
  The Development of Electrochemical Theories of the Course of Reactions of Carbon Compounds (Faraday Lecture), 245
  Awarded the Nobel Prize for Chemistry for 1947, 703 ; work of, 703
  Chemistry of Penicillin at the University of Oxford, 745
  Anniversary Address to the Royal Society, 782
  Elected president of the Royal Society for 1948, 782
  An Essay in Correlation arising from Alkaloid Chemistry, 815
Robinson, Sir Robert (Chakravarti, Dr. R. N., and) : Oxidation of Neostrychnine, 18
Robinson, Sir Robert (Cornforth, Dr. J. W., and) : Towards the Synthesis of Cholesterol, 737
Robson, —. : Progress in Nuclear Physics, 493
Robson, Dr. J. M. (Tadros, Dr. Wadie, and) : Highly Active Triphenylethylene Derivatives, 20
Rochester, Dr. G. D., and Butler, Dr. C. C. : Evidence for the Existence of New Unstable Elementary Particles, 855
Rockefeller Foundation : The Year's Work of the (Dr. Raymond B. Fosdick), 103
  Further grant to the University of Leeds for investigations into the molecular structure of biological tissues, 497
Rodger, A. : Selection for Management, 512
Rodger, Dr. T. Ferguson : Selection for Management, 512
Rogers, Dr. G. L. : Total Internal Reflection and Huyghens' Construction—the Immersion Grating, 25
Rollin, B. V., and others : Nuclear Magnetic Resonance at Low Temperatures, 436
Romanus, H. (Alfvén, Prof. H., and) : Valve with Trochoidal Electronic Motion, 614
Rooksby, H. P. : Technique of X-Ray Powder Photography, 7
  X-Ray Crystallographers in Industry, 29
Ropp, R. S. de : Plant Tumours and Animal Cancer, 780
Rosen, Dr. Gösta von : A Rapid Nigrosine Method for Chromosome Counts Applicable to Growing Plant Tissues, 121
Rosenfeld, Dr. L. : Appointed professor of theoretical physics at the University of Manchester, 83 ; work of, 83
Rosenhead, Prof. L. : Mathematics or Physics ?, *review*, 886
Rosicky, V. (F. Slavik), *review* by J. G. F. D., 735
Roskill, O. W. : The Technique and Applications of Market Research, 686
Ross, William : Awarded the Medal of Freedom with Bronze Palm by the Government of the United States, 513
Rotblat, Dr. J. : Progress in Nuclear Physics, 493
Roudier, A., and others : Structure of Starch—Mode of Attachment of the Side-chains in Amylopectin, 899
Rous, Peyton, and others : Science in Progress, edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
Rowbotham, P. : Methods of Crack Detection, 557
Rowe, A. P. : To establish a Defence Scientific Advisory Committee in Australia, 150
Rowe, W. H. : Our Forests, *review* by Prof. H. G. Champion, 106
Rowlands, Dr. S. : Application of the Cathode Ray Oscillograph to Measurements of Short Life-Periods of Radioactive Sources, 191
Roy, Dr. R. R. : Nuclear Explosion Recorded by Photographic Emulsion Method, 498
Royal Air Force : Air Council to set up an Educational Advisory Council for the, 253
Royal Aircraft Establishment : Electronic Equipment at the, 444
Royal Army Educational Corps : Exhibition of Visual Aids in Adult Education (Colonel J. T. Burgess), 411
  Retirement of Brigadier D. P. J. Kelly as controller, 600
Royal Astronomical Society : George Darwin Lecture (Prof. J. H. Oort), 203
  Geophysical discussion on Atmospheric Turbulence, 859
Royal College of Surgeons : Leverhulme Research Scholarships, 530
Royal Commission for the Exhibition of 1851 : Overseas Science Research Scholarships for 1947, 119
  Report of the Board of Management for the Years 1939–1946, 254
  Retirement of Sir Evelyn Shaw from the secretaryship, 861
Royal Geographical Society : Exhibition of Highways of the Air, 863
Royal Institute of Chemistry (Manchester and District Section) : Fourth Dalton Lecture (Dr. D. T. A. Townend), 530
Royal Institute of Chemistry, Dublin Section (Irish Chemical Association and the) : Colloquium on the Industrial Utilization of Agricultural Products and of Seaweed, 373
Royal Institution : The Work of the, in Physical Chemistry in Great Britain (Prof. E. K. Rideal), 245
Royal Netherlands Academy of Sciences : Election of Prof. Arthur Holmes as a member of the Section of Natural Sciences, 152
Royal Photographic Society : Annual Exhibition of Photography, 326, 618
Royal Sanitary Institute (Food and Nutrition Section) and the Food Group of the Society of Chemical Industry : Joint meeting on Milk, Tinned Foods and Bread, 307
Royal Society : Preliminary Report of the Empire Scientific Conference, 185
  To publish the collected correspondence of Isaac Newton, 461
  Medal Awards, 704, 839
  Anniversary Meeting, 782
  Election of Officers for 1948, 782
  Research appointments, 897
  To compile a list of British scientific societies, 898
Royal Society (Gassiot Sub-Committee B) : Conference on Emission Spectra of the Night Sky and Auroræ, 16
Royal Society of Arts : H.R.H. the Princess Elizabeth to become its president, 252
Royal Society of Edinburgh : Election of Sir Edward Appleton, Sir Alexander Fleming and Sir Arthur MacNalty as honorary fellows, 85
  Election of officers for 1947–48, 706
  Meeting in commemoration of the hundred and fiftieth anniversary of the death of James Hutton, 727
Royal Society of Medicine : Gold Medals awarded to Sir Alexander Fleming and Sir Howard Florey, 51
Royal Statistical Society : Election of Dr. David Heron as president, 85
Royal Swedish Academy of Sciences : Election of Prof. Arthur Holmes as a foreign member, 564
Rudall, Dr. K. M. (Reed, Dr. R., and) : Progress in Electron Microscopy, 762
Rudge, A. J., and others : Anode Phenomena in Molten Electrolytes, 504
Rufus, W. Carl, and Tien, Hsing Chih : The Soochow Astronomical Chart, *review*, 279
Rühl, Dr. W. : Science and Technical Education in Germany—Petroleum Geology, 724
Rule, Dr. H. Gordon (Schmidt, Dr. Julius, and) : A Text-Book of Organic Chemistry, revised and edited by Dr. Neil Campbell, fifth edition, *review*, 106
Runnström, Prof. J. : Elected president of the International Society for Cell Biology, 784
Rushman, D. F., and others : Curie Point of Barium Titanate, 58
Russell, Sir John : *Obituary* of Sir Albert Howard, 741
Russell, K. E. (Norrish, Prof. R. G. W., and) : Adsorption of Water Vapour in High-Vacuum Apparatus, 57
  Friedel-Crafts Catalysts in Polymerization—Kinetic Measurements and the Role of Water, 543
Russell, Dr. R. P. : The Organisation of Industrial Research, 547
Rusznyák, Prof. St., and others : Maturation of Megaloblasts in Bone Marrow Cultures, 757
Rutherford, Lord : World Federation of Scientific Workers Commemoration of the Tenth Anniversary of the death of, 806
Rutherglen, J. G. : Progress in Nuclear Physics, 494
Rutherglen, J. G., and Cole, J. F. I. : A Radio-Frequency Ion Source with High Percentage Yield of Protons, 545
Rutledge, W. A., and others : Gonadal Hormones and Mineral Balance in the Domestic Fowl, 541
Rydon, Dr. H. N. : Appointed to the University of London readership in organic chemistry at Birkbeck College, 326
Ryle, M., and Vonberg, D. D. : Relation between the Intensity of Solar Radiation on 175 Mc./s and 80 Mc./s, 157

SADLER, D. H. : The Navigational Work of the Nautical Almanac, 427
Sadowski, Dr. A., and others : Determination of Bilirubin in the Umbilical Blood as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn, 192
Saha, Dr. A. K. : Awarded an Overseas Science Research Scholarship for 1947 by the Royal Commissioners for the Exhibition of 1851, 119
Sahni, Prof. B. : Micropalæontology in Geology, *review*, 771
Sapiro, M. L. : Reaction of Nitrous Acid with Chlorophyll, 796
Sammartino, Rodolfo A. (Chiodi, Dr. Hugo, and) : Nephrotoxic and Renotropic Effects of Lead on White Rats and its Prevention by B.A.L., 680
Sandars, Edmund : An Insect Book for the Pocket, *review* by A. D. I., 553
Sanders, Prof. H. G. : Appointed Dean of the Faculty of Agriculture at the University of Reading, 357
Sanger, Dr. F. : Elected to a Beit Memorial Fellowship for Medical Research, 152
  Oxidation of Insulin by Performic Acid, 295
Sanger, Dr. F. (Tiselius, Prof. A., and) : Adsorption Analysis of Oxidized Insulin, 433
Sanger, Ruth, and Race, Dr. R. R. : Subdivisions of the *MN* Blood Groups in Man, 505
Sanitary Institute, Royal (Food and Nutrition Section) and the Food Group of the Society of Chemical Industry : Joint meeting on Milk, Tinned Foods and Bread, 307
Sarnoff, Brig.-General David : Pioneering in Television, 118
Saunders, Dr. B. C. : Toxic Properties of ω-Fluorocarboxylic Acids and Derivatives, 179
Savage, Spencer (compiled and annotated by) : A Catalogue of the Linnean Herbarium, *review* by Dr. W. B. Turrill, 73

Schmidt, Dr. Julius, and Rule, Dr. H. Gordon : A Text-Book of Organic Chemistry, revised and edited by Dr. Neil Campbell, fifth edition, *review*, 106
Schneider, Herbert W. : A History of American Philosophy, *review* by Prof. A. D. Ritchie, 37
Schnurmann, Dr. R. : Rheology of Minerals, 845
Schnurmann, Dr. R. (Morris, William John, and) : Mechanical Degradation of Large Molecules, 674
Schofield, Dr. R. Kenworthy : Calculation of Surface Areas from Measurements of Negative Adsorption, 408
Schönberg, Prof. Alexander, and others : Dimerization Reactions in Sunlight, 401
  A Crystalline Principle from *Ammi majus* L., 468
Schouten, —. : Mechanism of Colour Vision, 666
Science and its Social Relations, Committee on : First post-war meeting, 742
Science Museum : Exhibition to illustrate the achievements of British chemists during the past Century, 119, 245
  Exhibition on the Electron and its Applications, 358
  Electron Jubilee Exhibition, 460
  Chemical Society's Centenary Exhibition, 477
  Home and Factory Power Exhibition, 600
Science Writers (British), Association of : Formation and aims of the, 634
Scientific Advisory Committee for Defence in Australia : To be established by A. P. Rowe, 150
  Constitution of the, 150
Scientific Film Association, International : Formation of an, 601
Scientific Instrument Research Association, British : New laboratories of the, 15, 199
Scientific Panel, Interdepartmental : Work of the, 392
Scientific Societies, South-Eastern Union of : Fifty-first Annual Congress, 16
  Fifty-second Annual Congress, 342
Scientific Unions, International Council of: Annual Meeting of the Executive Committee, 218
  Reports of Proceedings of the Fourth General Assembly, 218
  First post-war meeting of the Committee on Science and its Social Relations, 742
Scientific Workers, Association of : Discussion on the International Control of Atomic Energy, 426
Scientific Workers, Association of (Agriculture Group) : Annual Conference, 601
Scientific Workers, Association of (Cambridge Senior Branch) : Conference on the Publication and Classification of Scientific Knowledge, 496, 649
Scientific Workers : The World Federation of (J. G. Crowther), 628
  Commemoration of the Tenth Anniversary of the death of Lord Rutherford, 806
Scientific and Industrial Research, Advisory Council for : Appointment of Prof. P. I. Dee and Sir William Griffiths as members, 530
  Retirement of Sir Lawrence Bragg, Sir John Lennard-Jones, Sir Andrew McCance and Sir Raymond Streat as members, 530
Scientific and Industrial Research, Department of : Opening of a Scottish Office in Edinburgh, 358
  Appointment of Dr. H. Buckley to be in charge of the Scottish Office, 358
  To establish a Mechanical Engineering Research Station in Scotland, 562
Scobey, R. R. : Hydrocyanic Acid and Poliomyelitis, 359
Scott, John M. C. : Awarded the Medal of Freedom with Bronze Palm by the Government of the United States, 513
Scott-Blair, Dr. G. W. : The Chemistry and Rheology of Clay, 512
Scottish Marine Biological Association : Annual Report for the Year 1945–46, 546
Scottish National Parks Committee : Report on National Parks and the Conservation of Nature in Scotland, 809
Scottish Office : Report on Industry and Employment in Scotland, 341
Scottish Seaweed Research Association : Opening of the Institute of Seaweed Research, 662
Scottish Society for Research in Plant Breeding : Twenty-sixth Annual Report, 862
Seaborg, Prof. Glenn T. : Peaceful Applications of Nuclear Fission, 453
  Nuclear Transformations in the new High Energy Ranges, 897
Seaweed Research : The Institute of (Dr. H. R. Fletcher), 662
Secondary School Examinations Council : Report on Examinations in Secondary Schools, 497
Seismology, Bibliography of (Dr. Ernest A. Hodgson), Vol. 13, No. 19, 898
Selbie, Dr. F. R. : Appointed to the University of London readership in bacteriology at Middlesex Hospital Medical School, 185
Select Committee on Estimates for the Session 1946–47 : Report of the, 379
Selényi, Dr. P., and Székely, Nicholas : Effect of Bending on Selenium Rectifier Disks, 197, *erratum*, 326
Selgin, Paul J. : Electrical Transmissions in Steady State, *review* by Dr. R. L. Smith-Rose, 206
Seligman, Gerald : Glaciological Research, 66
Selling, Dr. H. J. : Theory and Practice of Dyeing, 699
Semmens, Dr. Elizabeth S. : Starch Hydrolysis by Polarized Light, 669
Sen, Ranjit (Chakravarty, Dr. K. M., and) : X-Ray Diffraction Studies of a Nickel-Thoria-Kieselguhr Catalyst for Fischer-Tropsch Synthesis, 907
Sen Gupta, Prof. J. C., and Payne, Santosh Kumar : Leaf Heteromorphism and Photo-periods in *Sesamum orientale* L., 510
Sennett, R. S., and others : Specimen Changes due to Electron Bombardment in the Electron Microscope, 565
Seshappa, G. : Oviparity in *Littorina saxatilis* (Olivi), 335
Sewell, Dr. R. B. Seymour : *Obituary* of Prof. G. Matthai, 116
Seyler, Dr. C. A. : Geology and the Future of Coal Supplies, 593
Shaw, Sir Evelyn : Presentation to, by former Exhibition of 1851 Scholars, 861
Shaxby, Dr. J. H. : Dependence of Anomaloscope Matching on Viewing Distance or Field Size, 24
Sheehy, Dr. E. J. : Cobalt Deficiency in Sligo, 873
Sheffield, Dr. F. M. L. : Progress in Electron Microscopy, 762
Shepherd, W. C. F. : Speed Around the Initiating Point of the Detonation Wave in High Explosives, 92
Sheppard, N., and others : Infra-Red Spectrum and Molecular Structure of Phthiocerane, 580
Sheppard, Prof. P. A. : Atmospheric Turbulence, 860
Sherrington, Sir Charles : The Integrative Action of the Nervous System, *review* by Prof. E. D. Adrian, 623
Shockley, —. : Mechanical Properties of Metals, 696
Shoenberg, Dr. D. : Liquid Helium and its Properties, 387
Shoenberg, Dr. D. (Laurmann, E., and) : Penetration of Magnetic Field into Superconductors, 747
Sholl, Dr. Donald : Formulæ and Brain Weights, 805
Shoppee, Dr. C. W. : Nature of the C/D-Ring Union in the Oestrogenic Hormones, 64
Siddons, A. W., and others : A New Arithmetic, Parts 1, 2 and 3, and Notes and Answers, *review*, 279
Silberman, L. : Elected to a Beit Memorial Junior Fellowship for Medical Research, 152
Sillén, Dr. Lars Gunnar (Granér, Fredrik, and) : Hydrolysis of Bi^{3+}. Oxygen Bridging—a New Type of Ionic Equilibrium, 715
Simaika, Y. M., and others : The Nile Basin, Vol. 7, The Future Conservation of the Nile, 215
  A Long-Term Plan for the Nile Basin, 611
Simeone, Dr. Domingo H. (Monteverde, Dr. José J., and) : Chick Embryos Surviving the Inoculation of an Equine Strain of Encephalomyelitis Virus, 680
Simon, Prof. F. E. : Helium, *review*, 382
Simon, Colonel Leslie E. : German Research in World War II, 884
Simon of Wythenshawe, Lord : The Expansion of the Universities, 522
  The Proposal to Establish a Representative Universities Council, 523
Simon-Ruess, Mrs. I. (Mitchell, Prof. J. S., and) : Combination of some Effects of X-Radiation and a Synthetic Vitamin K Substitute, 98
Simonsen, Dr. J. L. : Science in the Colonies, 284
  Agricultural Products and the Chemical Industry, 373
  The Terpenes, Vol. I, The Simpler Acyclic and Monocyclic Terpenes and their Derivatives, second edition, revised by Dr. J. L. Simonsen and Dr. L. N. Owen, *review* by Prof. John Read, 384
Simpson, F. W. : Flow of Smoke through a Hole in Resonant Cavity, 93
Simpson, O. : Conductivity of Evaporated Films of Lead Selenide, 791
Simpson, O., and others : Lead Selenide Cells for Infra-Red Spectroscopy, 793
Simpson, T. B. : Honorary degree of LL.D. of the University of Edinburgh conferred on 668
Sina, Aly, and others : A Crystalline Principle from *Ammi majus* L., 468
Sinclair, D. C., and others : Significance of Multiple Innervation of Cutaneous Pain 'Spots' in relation to the Quality of Pain Sensibility, 27
Sinclair, Dr. J. : Appointed to the chair of mining at University College, Cardiff, 564
Sinha, S. P. (Pearse, Dr. R. W. B., and) : Absorption Bands of Li_2, Na_2, K_2, and NaK, 159
Sinsheimer, N. L., and Loofbourow, Prof. J. R. : Christiansen Filters for the Ultra-Violet, 674
Sirks, Dr. M. J. : Elected president of the International Union of Biological Sciences, 462
Sizoo, Prof. G. J. : Atomic Energy for Peaceful Purposes, 740
Skempton, A. W. : Rheology of Minerals, 844
Skinner, Dr. H. A. : The Electron Affinity of ClO, 716
  Structure of Cyclopropane, 902
Skinner, Dr. H. W. B. : Atomic Energy and the Veto, 460
Skorski, Roman (Benedicks, Dr. Carl, and) : Upper Yield Point—Occurrence in Bending Tests and Signification, 399
Slack, Mrs. P. Z., and Slack, R. : Phenazines and Benzcinnolines, 437, *erratum*, 497
Slankis, V. : Influence of the Sugar Concentration on the Growth of Isolated Pine Roots, 645
Slater, Dr. N. B. : Absolute Values of the Rates of Unimolecular Reactions, 576
  Appointed honorary curator of the Cecil Duncombe Observatory of the University of Leeds, 745
Slater, P. : Awarded a grant from the Leverhulme Research Fellowships, 119
Slater, Dr. W. K. : British Needs and Resources of Calories, Protein and Calcium, 702
Slätis, Prof. Hilding : β- and γ-Radiation from U^{239} and Np^{239}, 579
Slavik, F. : V. Rosicky, *review* by J. G. F. D., 735
Slichter, Prof. Louis B., and Bullard, Dr. E. C. : Frenkel's Views on the Origin of Terrestrial Magnetism, 157
Slichter, Dr. Sumner H. : Some Economic Consequences of Science, 622
Slome, Dr. David : Appointed to the University of London readership in physiology at Middlesex Hospital Medical School, 326
Slome, Dr. David, and others : Physiological Effects of Alkyl Polyphosphates, 760
Smid, Jan : Appointed field science officer at the Field Science Co-operation Office of U.N.E.S.C.O. at Nanking, 529 ; work of, 529
Smith, Dr. A. E. Wilder : Metabolism of Synthetic Œstrogens in Man, 787
Smith, Dr. C. L. : Thermal Hardening of Cadmium Crystals, 466
Smith, Dr. F. : Appointed professor of chemistry in the University of Minnesota, 85
Smith, Sir Frank : Awarded the Medal of Freedom with Silver Palm by the Government of the United States, 513
Smith, Dr. G. F. Herbert : Nature Protection in Great Britain, 457
Smith, I. C. P. : Spiral Cracks in Glass Tubing, 232
Smith, Dr. J. A. B. : Appointed deputy director of the Hannah Dairy Research Institute, 360
Smith, Prof. J. G. : Presentation to, on retirement from the post of Vice-principal of the University of Birmingham, 85
Smith, Dr. Malcolm A. : Elected president of the British Herpetological Society, 394
Smith, Dr. Mary : Series of lectures at the International School in Social Biology, 803
Smith, Sir William Wright : Elected president of the Royal Society of Edinburgh for 1947–48, 706
Smith-Rose, Dr. R. L. : Radio Transmission Lines and Wave Guides, *review*, 206
  Awarded the Medal of Freedom with Silver Palm by the Government of the United States, 513
Smithson, Dr. F. (Johnson, R., and) : A Sedimentation Phenomenon, 26
Smithson, N. L., and others : A New Source of Taraxerol, 577
Smithsonian Institution : Classified List of Publications available for Distribution (H. Munroe), 394
Snell, K. S., and others : A New Arithmetic, Parts 1, 2 and 3, and Notes and Answers, *review*, 279
Snoek, Dr. J. L. : Gyromagnetic Resonance in Ferrites, 90
  Mechanical Properties of Metals, 696
Snyder, Laurence H., and others : Genetics, Medicine and Man, *review* by Prof. F. A. E. Crew, 590

Social Hygiene Council, British : Conference on Society and the Individual, 706
Conference on Biology in Education, 785
International School in Social Biology, 803
Society for Visiting Scientists : Discussion of Law-making in Science, 530
Soil Science, British Society of : Conference on Problems of Soil and Land Classification, 686
Sokolovskaya, I. I. (Milovanov, V. K., and) : Stockbreeding and the Artificial Insemination of Livestock, translated by Dr. A. G. Morton, *review* by John Hammond, 209
Sols, Dr. A. : An Improved Biuret Reaction of Proteins and the Two-Standard Colorimetry, 89
Somerville, Dr. John : Soviet Philosophy, *review* by Lord Lindsay of Birker, 36
Sommer, Dr. A. : Photoelectric Cells, *review* by Dr. L. E. C. Hughes, 854
Sontakay, K. R. : Pests of Stored Foods, 739
Soole, B. W., and others : Occurrence of Random Photovoltaic Barriers in Photoconductive Layers, 471
Soskin, Prof. Samuel, and Levine, Dr. Rachmiel : Carbohydrate Metabolism, *review* by Prof. J. H. Quastel, 107
Sosnowski, L., and others : Occurrence of Randon Photovoltaic Barriers in Photoconductive Layers, 471
South Africa, Archæological Survey of the Union of: Report for 1940–46, 785
South African Science, No. 1, 291
South African Association for the Advancement of Science : *South African Science*, No. 1, 291
South-Eastern Union of Scientific Societies : Fifty-first Annual Congress, 16
Fifty-second Annual Congress, 342
Southgate, Dr. B. A., and Jenkins, Dr. S. H. : Pollution by Trade Wastes from Food Industries, 200
Southwell, Dr. R. V. : Relaxation Methods, a Method for the Engineer, 462
The Expansion of the Universities, 522
Southwest Research Institute of San Antonio, Texas : Opening of the, 822
Sparkes, Dr. S. R. : Title of University of London reader in civil engineering conferred on, 185
Speakman, Prof. J. B. : The Production, Properties and Uses of Seaweed Rayon, 373
Special Libraries and Information Bureaux, Association of : Twenty-second Annual Conference, 293
Special Libraries and Information Services, Association of : Publication of the first issue of *Information*, 897
Speidel, Carl Caskey, and others : Science in Progress, edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
Spensley, P. C., and others : Benziminazoles related to Paludrine, 53
Spiegelman, S., and others : Physiological Heterogeneity of Metaphosphate in Yeast, 717
Spilsbury, Sir Bernard : *Death* of, 896
Spooner, Prof. E. C. R. Appointed professor of mining and metallurgy at the University of Adelaide, and director of the Bonython Laboratories at the South Australian School of Mines and Industries, 150 ; work of, 150
Sproule, D. O. : Methods of Crack Detection, 557
Absorption of Ultrasonic Waves in Liquids, 914
St. Bartholomew's Hospital Medical College : Appointment of Dr. K. J. Franklin to the University of London chair of physiology, 16, 599
St. John-Brooks, Dr. Ralph : Fourth International Congress for Microbiology, 596
St. Thomas's Hospital Medical School : Appointment of Dr. F. T. G. Prunty to the University of London readership in chemical pathology, 185
Appointment of Prof. Henry Barcroft to the University of London chair of physiology, 601, 704
Appointment of Dr. T. D. Day to the University of London readership in pathology, 601
Staehelin, Dr. D., and Voegtli, Dr. W. : Alloxan Diabetes and Glycogen Phosphorolysis in Rats, 363
Stagg, Dr. J. M. : Recordings at Kew of the Brest Explosion, 184
The International Union of Geodesy and Geophysics, 558
Stakman, E. C., and others : Science in Progress, edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
Ställberg-Stenhagen, S., and others : Infra-Red Spectrum and Molecular Structure of Phthiocerane, 580
Standardisation, International Organisation for : First meeting of the Council, 389
Standards Institution, British : Election of Lord McGowan as president, 16
Election of Sir Clifford Paterson as chairman of the General Council, 16
Stanfeld, E. D. : Appointed superintendent, Crown Lands and Surveys, Hong Kong, 152
Stanford, E. G. : Methods of Crack Detection, 557
Stanner, Lieut.-Colonel W. E. H. : Appointed director of the East African Institute of Social Research, 117
Stanton, Miss B. R., and others : British Needs and Resources of Calories, Protein and Calcium, 700
Starkie, Dr. D. : Plastic Optical Systems for Television, 99
Starkiewicz, J., and others : Occurrence of Random Photovoltaic Barriers in Photoconductive Layers, 471
State Laboratory for Experimental Biology and Medicine, Novi Sad, Yugoslavia (Dr. Petar N. Martinovitch), 476
Statistical Society, Royal : Election of Dr. David Heron as president, 85
Staub, Prof. H. R. : Progress in Nuclear Physics, 492
Stebbing, Prof. E. P. : The Teak Forests of Burma, 818
International Timber Conference, 878
Stehanov, A. (Gross, Prof. E., and) : Temperature Variation of the Second-Order Raman Spectrum of Crystals, 568
Steinberg, J.-L. : Production of High-Frequency Energy by Ionized Gases, 833
Steinitz, H. (Haas, Dr. G., and) : Erythrean Fishes on the Mediterranean Coast of Palestine, 28
Stenhagen, Prof. E., and others : Infra-Red Spectrum and Molecular Structure of Phthiocerane, 580
Stephen, Miss J. M. L. (Butler, Dr. J. A. V., and) : An Apparatus for Preparative Electrophoresis, 469
Stephensen, K. H. : *Obituary* by Dr. Anton Fr. Bruun, 82
Stepka, W., and others : Detection of the Free Amino-Acids of Plant Cells by Partition Chromatography, 682
Sterling, E. (Arthur, J. R., and) : Use of a Palladium Tube Technique in the Study of the Role of Hydrogen in Combustion Systems, 869
Stern, F. C. : A Study of the Genus Pæonia, *review* by Dr. George Taylor, 551
Steven, D. M. : Astacene in the Brown Trout, 507
Carotenoid Pigmentation of Trout, 540
Steward, Prof. F. C., and others : Detection of the Free Amino-Acids of Plant Cells by Partition Chromatography, 682
Stewart, Prof. A. W. : *Obituary* by Dr. D. N. McArthur, 116
Stewart, G. S. (Hey, J. S., and) : Radio Reflexions from Meteoric Ionization, 74
Stiles, Dr. W. S. : Mechanism of Colour Vision, 664
Colour Phenomena in the Perception of Fine Detail, 880
Stokes, Dr. Alexander R. : Radiation Pressure, 532
Stoneley, Dr. R. : Awarded a Leverhulme Research Fellowship for 1947, 119
Stoner, C. R. : Title of University of London reader in electrical engineering conferred on, 16
Stoner, Prof. E. C., and Wohlfarth, E. P. : Interpretation of High Coercivity in Ferromagnetic Materials, 650
Stoppani, Dr. A. O. M. : Constitution of the Succinate and α-Glycerophosphate Oxidase Systems, 52
Stout, H. P. : Electrode Processes, 306
Streat, Sir Raymond : Retirement as a member of the Advisory Council for Scientific and Industrial Research, 530
Strickland, Dr. Cyril : *Obituary*, 820
StripSlides : The Principles of Bridges, 393
Stuart-Harris, C. H., and others : Chemotherapeutic and other Studies of Typhus, 726
Stubbings, W. V., and others : A Rapid Method of Analysis for certain Surface-Active Agents, 909
Stuckey, Dr. R. E. : Reported Preparation of Mercaptoimidazole Derivatives by Methylation of 3 : 5-Disubstituted Thiohydantoins, 189
Sturtevant, Prof. A. H. : White-eyed Mutants of Diptera, 754
Sugden, T. M. : Structure of Cyclopropane and Ethylene Oxide, 367
Sukhatme, Dr. P. V. : Use of Small-size Plots in Yield Surveys, 542
Sumner, W. L. : Science and Life in the World, *review*, 141
Science in Progress, *review*, 519
Surgeons, Royal College of : Leverhulme Research Scholarships, 530
Suryanarayana, D. (Bhagavantam, Prof. S., and) : Third-Order Elastic Coefficients of Crystals, 750
Sutherland, Dr. G. B. B. M., and Jones, A. Vallance : Use of Polarised Radiation in Infra-Red Analysis, 567
Sutherland, Dr. G. B. B. M., and others : Infra-Red Spectrum and Molecular Structure of Phthiocerane, 580
Lead Selenide Cells for Infra-Red Spectroscopy, 793
Sutherland, Maurice D. (Briggs, Dr. Lindsay H., and) : A Terpene-type Essential Oil from a Fern (*Paesia scaberula*), 333
Sutton, L. E., and others : Dipole Moments and Structure of the Sydnones, 366
Sutton, Muriel : Feeding Mechanism of Water-bugs, 122
Sutton, Prof. O. G. : Atmospheric Turbulence, 860
Swainger, Dr. K. H. : Large Strains and Displacements in Stress-Strain Problems, 399
Swanton, John R. : Indians of the South-Eastern United States, 898
Swedish Academy of Sciences, Royal : Election of Prof. Arthur Holmes as a foreign member, 564
Swider Geophysical Observatory : Stanislaw Kalinowski and the, 359
Swift, Stewart : Milk, Tinned Foods and Bread, 307
Swinton, Dr. W. E. : *Obituary* of Dr. John Parkinson, 390
Swiss Broadcasting Corporation : To give short-wave service of daily sun-spot numbers, 293
Sword, Dr. J. : Milk, Tinned Foods and Bread, 308
Swyer, G. I. M. : Absence of Hyaluronidase from Reptilian Testes, 433
Swyer, G. I. M. (Emmens, Dr. C. W., and) : Maintenance of Spermatozoal Motility in Dilute Suspension, 718
Sydowia : To be published by Dr. F. Petrak, 292
Symonds, J. : Progress in Nuclear Physics, 494
Synge, Prof. J. L. : Short course of lectures at the Dublin Institute for Advanced Studies, 393
Systematics Association (Linnean Society in conjunction with the) : Course of lectures on the Principles and Methods of Taxonomy, 564
Székely, Nicholas (Selényi, Dr. P., and) : Effect of Bending on Selenium Rectifier Disks, 197, *erratum*, 326
Szent-Györgyi, Prof. A. : Honorary degree of D.Sc. of the University of Oxford conferred on, 152
Chemistry of Muscular Contraction, *review* by Dr. Kenneth Bailey, 550
Szigeti, G., and Nagy, E. : Dielectric Losses and Fluorescence of Zinc Silicate, 641
Szwarc, Dr. M. : The C—H Bond Energy in Toluene and Xylenes, 403

TADROS, Dr. Wadie, and Robson, Dr. J. M. : Highly Active Triphenylethylene Derivatives, 20
Talbot, Benjamin : *Death* of, 896
Tammes, Prof. Tine : *Death* of, 495
Tanner, Prof. V. : Outlines of the Geography, Life and Customs of Newfoundland—Labrador (the Eastern Part of the Labrador Peninsula), *review*, 735
Tansley, Prof. A. G. : Acceptance of the office of president of the Council for the Promotion of Field Studies, 84
Tata Institute of Fundamental Research, 112
Tate, Dr. P. : A Sex-linked and Sex-limited White-eyed Mutation of the Blow-fly (*Calliphora erythrocephala*), 361
Taylor, Dr. A. : Training of X-Ray Crystallographers in Polytechnics and Universities, 30
Taylor, Prof. A. M. (Crook, A. W., and) : Temperature Coefficient of Rotation of Quartz in the Ultra-Violet Region, 396
Taylor, Dr. C. B. : Reduction of Potassium Permanganate in the Presence of Glass, 56
Some Aspects of the Bacteriology of Lakes and Streams, 584
Taylor, Dr. D. B. (Quilliam, J. P., and): Antagonism between Curare and the Potassium Ion, 603
Taylor, Prof. E. G. R. : Geography in War and Peace, 285
Taylor, E. Wilfred, and Payne, B. O. : A Variable Phase-Contrast System for Microscopy, 338
Taylor, Dr. E. Windle : Bacteriology of Water, 584

Taylor, Dr. F. Sherwood : The Chemical Society, 6
  A Century of British Chemistry, 84
Taylor, Dr. F. Sherwood (edited by) : Chemical Progress, 477
Taylor, Dr. George : Peonies, *review*, 551
Taylor, Hugh S., and others : Science in Progress, edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
Taylor, Sydney E. : Elected president of the Institution of Mining and Metallurgy for 1948–49, 898
Taylor, Dr. W. H. : Training of X-Ray Crystallographers in Polytechnics and Universities, 29
Technische Hochschule, Darmstadt : International Congress for Technical Education (James T. Kendall), 721
Teegan, J. P. : Awarded an Overseas Science Research Scholarship for 1947 by the Royal Commissioners for the Exhibition of 1851, 119
Tegul, S. (Constable, Prof. F. H., and) : Silicic Acid, 55
Teideman, S. J. : Some Interesting Birds of Pagham Harbour, 343
Temperley, Dr. H. N. V. : Absorption of Ultrasonic Waves in Liquids, 913
Temple, Prof. George : Appointed chief scientific adviser to the Minister of Civil Aviation, 185
Templeman, Dr. W. G. (Rhodes, A., and) : Effect of 4-Chloro-2-Methyl Phenoxyacetic Acid on the Mineral Content and Growth of Plants, 825
Tendeloo, Prof. H. J. C. : Electrode Processes, 307
Thackeray, Dr. A. D. : Spectrum of ρ Cassiopeiae, 370
  A Short-lived Solar Phenomenon in High Latitude, 439
Thimann, Assoc. Prof. Kenneth V. (edited by Harris, Prof. Robert S., and) : Vitamins and Hormones, Vol. 4, *review* by Dr. Leslie J. Harris, 242
Thoday, Dr. J. M. : Appointed assistant lecturer in botany and zoology in the University of Sheffield, 85
Thoday, Dr. J. M., and Read, John : Effect of Oxygen on the Frequency of Chromosome Aberrations produced by X-Rays, 608
Thom, A. S. (Hinde, R. A., and) : Breeding of the Moustached Warbler in Britain, 636
Thomas, C. C., and others : Chemotherapeutic and other Studies of Typhus, 726
Thomas, Dr. H. Hamshaw : The History of Plant Form, 288
Thomas, Dr. L. A. : New Industrial Techniques and Results of X-Ray Crystallography, 31
Thompson, A. : Elected president of the British Bryological Society, 428
Thompson, Dr. H. W. (Mann, J., and) : Absorption Spectra with Polarized Infra-Red Radiation, 17
Thomson, Sir George : At the Jubilee Celebrations of the Discovery of the Electron, 776
Thomson, Prof. Godfrey : The Basis of Selection of Students, 552
Thomson, Sir William : *Death* of, 220
Thorp, J. M., and Meillon, Dr. Botha de : Inhibition of the Toxicity of 'Gammexane' for Insects, 264
Thorp, R. H., and others : Optical Isomers of Amidone, with a Note on *Iso*Amidone, 605
Thorpe's Dictionary of Applied Chemistry, Fourth edition, Vol. 7, Iodazide—Metallagic Acid, *review* by B. A. Ellis, 624 ; Vol. 8, Methal-Oils, Essential, *review* by Sir Norman Haworth, 692
Thorson, Dr. Gunnar : Reproduction and Larval Development of Danish Marine Bottom Invertebrates, 766
Tickner, A. W. (Harris, Prof. G. M., and) : Reaction of Hydrogen Atoms with Solid Carbon, 871
Tien, Hsing Chih (Rufus, W. Carl, and) : The Soochow Astronomical Chart, *review*, 279
Tillotson, Ernest : Microseisms and Atmospheric Oscillations, 321
  Dutch Pioneers in Science and Industry, *review*, 449
Tingle, E. D. : Influence of Water on the Lubrication of Metals, 710
Tiselius, Prof. A., and Sanger, Dr. F. : Adsorption Analysis of Oxidized Insulin, 433
Titchmarsh, Prof. E. C. : Eigenfunction Expansions associated with Second-Order Differential Equations, *review*, 174
Tizard, Sir Henry : Elected president for 1948 of the British Association for the Advancement of Science, 324
Toit, Dr. P. J. du : D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in South Africa, 485
Tolansky, Prof. S. : High Resolution Spectroscopy, *review* by Dr. D. A. Jackson, 244
  Autumn Conference of the German Physical Society in the British Zone, 723
  Structure of Spectral Lines, 909
Tomich, Edward G. : Methionine in Urine, 604
Tomkeieff, Dr. S. I. : Analytical Geology, 846
Toms, A. H. : Soil in Civil Engineering, 343
Torriani, Annamaria (Gorini, Dr. Luigi, and) : Biochemistry of *Escherichia coli* and the Production of Penicillinase, 332, *errata*, 394
Touschek, Dr. Bruno : Excitation of Nuclei by Electrons, 500
Towers and Co., Ltd. : 'Isomantle' for the Heating of Flasks, 862
Townend, Dr. D. T. A. : Fuel and Chemistry, 530
  Appointed director-general of the British Coal Utilization Research Association, 706
Trade, Board of : Working Party Reports—The Lace Industry, 879
Treloar, Dr. : The Chemistry and Rheology of Clay, 512
Tress, Dr. H. J. : Appointed lecturer in glass technology in the University of Sheffield, 564
Trewavas, Dr. Ethelwynn : Speciation in Cichlid Fishes of East African Lakes, 96
  'Mimicry' in Fishes, 120, 509
Trinity College, Cambridge : Research Studentships and Dominion and Colonial Exhibitions, 898
Tristram, Dr. G. R. : Constitution of Salmine, 637
Trotter, A. P. : *Obituary* by J. S. Dow, 390
Trout, G. C. : British Needs and Resources of Calories, Protein and Calcium, 701
Trowell, Dr. O. A. : Function of the Lymphocyte, 845
Twomey, D., and others : Antitubercular Activity of Diphenyl Ethers and related Compounds, 800
Tulasne, Dr. R., and Vendrely, Dr. R. : Demonstration of Bacterial Nuclei with Ribonuclease, 225
Tunstall, N. : Training of X-Ray Crystallographers in Polytechnics and Universities, 30
Türkiye Geoloji Kuruma : Objects and activities of the, 16
Turner, H. A. : Theory and Practice of Dyeing, 698
Turner, Asst. Prof. John P., and others : Atlas of Outline Drawings for Vertebrate Anatomy, *review* by Dr. W. S. Bullough, 813
Turner, Prof. J. S., and Hanly, V. : Malonate and Plant Respiration, 296, *erratum*, 530
Turrill, Dr. W. B. : The Linnean Herbarium, *review*, 73
Tustin, Prof. A. : The Nature of the Operator's Response in Manual Control, 341
Twohig, J. P. : The Production, Properties and Uses of Seaweed Rayon, 373
Twomey, Dr. T. ; The Production, Properties and Uses of Seaweed Rayon, 373
Tyler, Dr. Cyril : Appointed to the chair of agricultural chemistry in the University of Reading, 357
Tyndall, Prof. A. M. : At the Jubilee Celebrations of the Discovery of the Electron, 776
Tzanck, A., et autres : Précis de dermatologie, cinquième édition par A. Civatte, *review* by Dr. James Marshall, 592
Tzu, H. Y. : Universal Constants in Blackett's Formula, 746

UBBELOHDE, Prof. A. R. : Time and Thermodynamics, *review* by Dr. J. A. V. Butler, 72
Ubbelohde, Prof. A. R., and Mackle, H. : Bond-Strengths of Methyl-Iodine and Methyl-Magnesium, 303
Ubbelohde, Prof. A. R. (Pink, R. C., and) : Structure and Diamagnetic Susceptibility of Cyclo-octatetraene, 502
Ulehla, Prof. V. : *Obituary* by J. G. F. D., 560
Underwood, Dr. E. Ashworth : An Early Nineteenth Century American Medical Man, *review*, 38
  Awarded the Cross of the Chevalier of the Legion of Honour, 462
  Obituary of Dr. S. H. Daukes, 560
U.N.E.S.C.O. : Names of the United Kingdom delegation to the second General Conference, 497
  Appointment of Jan Smid as field science officer at the Field Science Co-operation Office at Nanking, 529
  British Association discussion on, 689
  Fellowships awarded to Dr. Milos Hudlicky, Dr. Ivan Vavruch and Charalambos Vacalopoulos, 706
  Request to the International Bureau of Physico-Chemical Standards to establish a collection of pure chemical substances, 822
U.N.E.S.C.O. and American Participation in its Activities (American Philosophical Society symposium on), 360
United Nations (Food and Agriculture Organisation of the) : Conference on Infestation of Stored Foodstuffs, 51, 739
  Report of the International Timber Conference, 878
United Nations Educational, Scientific and Cultural Organisation : Names of the United Kingdom delegation to the second General Conference, 497
  Appointment of Jan Smid as field science officer at the Field Science Co-operation Office at Nanking, 529
  British Association discussion on, 689
  Fellowships awarded to Dr. Milos Hudlicky, Dr. Ivan Vavruch and Charalambos Vacalopoulos, 706
  Request to the International Bureau of Physico-Chemical Standards to establish a collection of pure chemical substances, 822
United Nations Educational, Scientific and Cultural Organisation and American Participation in its Activities (American Philosophical Society symposium on), 360
United Nations Organisation : Teacher's Guide to the (British Society for International Understanding), 529
United States, Government of the : Awards to British Men of Science, 291, 513
United States Atomic Energy Commission : 'Fast Fission Pile' in operation at the Los Alamos Laboratory, 426
United States Coast and Geodetic Survey : Transfer of the seismograph station at Honolulu from the University of Hawaii to the Honolulu Magnetic and Seismological Observatory of the, 530
United States Embassy in London : Scientific Mission to be established at the, 633
United States National Academy of Sciences : Elections and Awards, 168
  Officers of the, 563
United States National Research Council : Fellowships in the Natural Sciences, 824
University of Aberdeen : Honorary degree of LL.D. conferred on Prof. C. D. Broad, 51
  Degree of Ph.D. conferred on K. Hassan, 51
  Degree of M.D. conferred on L. D. M. Gavin, 51
  Appointment of Dr. W. T. H. Williamson as lecturer in charge of the Department of Soil Science, 428
University of Adelaide : Appointment of Prof. E. C. R. Spooner as professor of mining and metallurgy and director of the Bonython Laboratories at the South Australian School of Mines and Industries, 150
University of Alberta : Appointment of J. A. Harle as professor of electrical engineering, 83
University of Auckland : Appointment of Dr. F. J. Llewellyn as professor of chemistry, 85
University of Birmingham : Appointment of P. B. Medawar to the chair of zoology, 14
  Appointment of Dr. T. L. Hardy as professor of gastroenterology, 85
  Appointment of Dr. J. F. Brailsford as honorary director of radiological studies in living anatomy, 85
  Honorary degree of D.Sc. conferred on Dr. O. R. Frisch, 85
  Degree of D.Sc. conferred on F. A. Fox, J. K. N. Jones, J. H. Partridge, W. T. Pell-Walpole and L. F. Wiggins, 85
  Presentation to Prof. J. G. Smith on retirement from the post of vice-principal, 85
  Appointment of Sir Norman Haworth as vice-principal, 85
  Conference on Fundamental Physical Theory, 627
  Chair of genetics to the established in the Faculty of Science, 863
University of Bristol : Summer school and conference on the Mechanical Properties of Metals, 696
  Annual Report for 1945 of the Agricultural and Horticultural Research Station at Long Ashton, 881
University of Cambridge : Summer School in Physical Chemistry in the Department of Physical Chemistry, 292

- University of Edinburgh : Honorary degree of LL.D. conferred on Dr. H. W. Featherstone and T. B. Simpson, 668
- University of Glasgow : Opening of the Henderson Laboratory in the Department of Chemistry, 14
  - Honorary degree of LL.D. conferred on Sir Robert Robinson, 14
  - Appointment of Prof. James Norman Davidson to the Gardiner chair of physiological chemistry, 51
  - Retirement of Prof. E. P. Cathcart from the regius chair of physiology, 117
  - Appointment of Prof. R. C. Garry to the regius chair of physiology, 117
- University of Hawaii : To sponsor a new journal, *Pacific Science*, 254
  - Transfer of the seismograph station at Honolulu to the Honolulu Magnetic and Seismological Observatory of the U.S. Coast and Geodetic Survey near Barber's Point, Oahu, 530
- University of Lausanne : Offer of the Prix Arnold Reymond, 745
- University of Leeds : Report to the Cloth-workers' Company of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing for 1945–46, 185
  - Grant of £60,000 from Courtaulds, Ltd., for building and equipping a Division of Rayon Technology in the Department of Textile Industries, 186
  - Further grant from the Rockefeller Foundation for the investigations of Prof. W. T. Astbury into the molecular structure of biological tissues, 497
  - Appointment of E. A. Vaughan as lecturer in the Department of Social Studies, 563
  - Appointment of A. Johnson and L. G. Johnson as lecturers in the Departments of Economics and Extra-Mural Studies, 563
  - Appointment of Edward Broadhead as lecturer in zoology, 563
  - Appointment of J. D. Jenkins as lecturer in mining, 563
  - Appointment of H. J. King as lecturer in surveying, 563
  - Appointment of Dr. W. J. Allen and Dr. R. A. Kenney as lecturers in physiology, 563
  - Appointment of S. Dagley as lecturer in biochemistry, 563
  - Appointment of G. A. Nelson as lecturer in pharmacognosy, 563
  - Appointment of Dr. N. B. Slater as honorary curator of the Cecil Duncombe Observatory, 745
  - Appointment of J. Mars as lecturer in economics, 745
  - Appointment of D. Johnston as lecturer in metallurgy, 745
  - Nomination of Charles R. Morris as vice-chancellor, 863
- University of Liverpool : Appointment of Dr. W. J. Kearton to the Harrison chair of mechanical engineering, 706
- University of London : Appointment of Dr. K. J. Franklin to the University chair of physiology at St. Bartholomew's Hospital Medical College, 16
  - Appointment of Dr. Margaret M. A. Murray to the University chair of physiology at Bedford College, 16
  - Appointment of Dr. Margaret Fishenden to the University readership in applied heat at the Imperial College of Science and Technology, 16
  - Appointment of H. E. O. James to the University readership in psychology at the University of London Institute of Education, 16
  - Title of University reader in commerce conferred on Frederick Brown, 16
  - Title of University reader in electrical engineering conferred on C. R. Stoner, 16
  - Degree of D.Sc. conferred on W. J. Martin and K. R. S. Morris, 16
  - Retirement of Harold Claughton from the principalship, 51
  - Appointment of Dr. D. W. Logan as principal, 51, 824
  - Honorary degrees conferred on Prof. C. N. Hinshelwood, Prof. J. N. Brønsted, Prof. P. Karrer and Prof. L. C. Pauling, 85
  - Appointment of E. H. Phelps Brown to the University chair of economics of labour at the London School of Economics, 185
  - Appointment of Dr. Harold Burton to the University chair of chemistry at King's College of Household and Social Science, 185
  - Appointment of P. T. Bauer to the University readership in agricultural economics at the London School of Economics, 185
  - Appointment of R. H. Coase to the University readership in economics at the London School of Economics, 185
  - Appointment of Dr. P. C. C. Garnham to the University readership in medical parasitology at the London School of Hygiene and Tropical Medicine, 185
  - Appointment of J. W. H. King to the University readership in civil engineering at Queen Mary College, 185
  - Appointment of Dr. M. M. Loève to the University readership in applied mathematics at Birkbeck College, 185
  - Appointment of Dr. F. T. G. Prunty to the University readership in chemical pathology at St. Thomas's Hospital Medical School, 185
  - Appointment of Dr. Richard Rado to the University readership in pure mathematics at King's College, 185
  - Appointment of Dr. F. R. Selbie to the University readership in bacteriology at Middlesex Hospital Medical School, 185
  - Title of University professor of zoology conferred on Dr. Alastair Graham, 185
  - Title of University professor of zoology conferred on Dr. A. J. Grove, 185
  - Title of University reader in pure mathematics conferred on Dr. R. G. Cooke, 185
  - Title of University reader in civil engineering conferred on Dr. S. R. Sparkes, 185
  - Degree of D.Sc. conferred on Prof. E. J. King, 185
  - Appointment of Dr. William Burns to the University chair of physiology at Charing Cross Hospital Medical School, 326
  - Appointment of W. G. East to the University chair of geography at Birkbeck College, 326
  - Appointment of Prof. L. A. Reid to the University chair of philosophy of education at the Institute of Education, 326
  - Appointment of Dr. H. N. Rydon to the University readership in organic chemistry at Birkbeck College, 326
  - Appointment of Dr. David Slome to the University readership in physiology at Middlesex Hospital Medical School, 326
  - Appointment of Dr. E. W. Balls to the University readership in anatomy at Middlesex Hospital Medical School, 326
  - Title of University professor of bacteriology as applied to hygiene conferred on Dr. J. C. Cruickshank, 326
  - Title of University reader in medical mycology conferred on Dr. J. T. Duncan, 326
  - Title of University reader in social economics conferred on Mrs. Gertrude Williams, 326
  - Appointment of M. McGregor to the University chair of agriculture at Wye College, 462
  - Appointment of Prof. W. J. Hamilton to the University chair of anatomy at Charing Cross Hospital Medical School, 462
  - Appointment of Prof. W. G. Holford to the University chair of town planning at University College, 462
  - Appointment of Dr. W. A. Lewis to the University readership in Colonial economics at the London School of Economics, 462
  - Title of University reader in mining geology conferred on Dr. David Williams, 462
  - Conference of Home Universities, 522
  - Appointment of Dr. K. J. Franklin to the University chair of physiology at St. Bartholomew's Hospital Medical College, 599
  - Appointment of Prof. Henry Barcroft to the University chair of physiology at St. Thomas's Hospital Medical School, 601, 704
  - Appointment of Dr. T. D. Day to the University readership in pathology at St. Thomas's Hospital Medical School, 601
  - Appointment of Dr. Russell Fraser to the University readership in medicine at the British Postgraduate Medical School, 601
  - Appointment of Dr. C. J. O. R. Morris to the University readership in chemical pathology at London Hospital Medical College, 601
  - Title of University professor emeritus of mining geology conferred on Prof. W. R. Jones, 601
  - Degree of D.Sc. conferred on Sachindranath Dasgupta, Norman Davy, R. L. Knight, W. S. Martin, Prof. Claude Rimington and Yung Chow Wong, 601
  - Appointment of W. D. Hogarth to be clerk of the University Court, 824
  - Appointment of Dr. L. P. Mair to the University readership in Colonial administration at the London School of Economics and Political Science, 824
  - Appointment of Dr. N. F. Maclagan to the University chair of chemical pathology at Westminster Hospital Medical School, 824
  - Degree of D.Sc. conferred on Conrad Ellenby and G. M. Dyson, 824
- University of London Institute of Education : Appointment of H. E. O. James to the University readership in psychology, 16
  - Appointment of Prof. L. A. Reid to the University chair of philosophy of education, 326
- University of Manchester : Appointment of Dr. L. Rosenfeld as professor of theoretical physics, 83
- University of Minnesota : Appointment of Dr. F. Smith as professor of chemistry, 85
- University of Oxford : Appointment of Prof. Linus C. Pauling as George Eastman visiting professor, 16
  - Honorary degree of D.Sc. conferred on Prof. S. A. S. Krogh, Prof. A. Szent-Györgyi, Dr. H. S. Gasser, Prof. B. A. Houssay and Dr. C. H. Best, 152
  - Degree of D.Sc. conferred on Prof. C. H. Best, Prof. H. S. Gasser, Prof. B. A. Houssay, Prof. August Krogh and Prof. A. Szent Györgyi, 249
  - Chemistry of Penicillin at the (Sir Robert Robinson), 745
- University of Pennsylvania : To issue an annual publication on the history of chemistry, entitled *Chymia*, 84
  - Publication of *Chymia* to be sponsored by the Edgar Fahs Smith Memorial Collection, 292
- University of Reading : Retirement of Prof. H. A. D. Neville from the chair of agricultural chemistry and as Dean of the Faculty of Agriculture, 357
  - Appointment of Dr. Cyril Tyler to the chair of agricultural chemistry, 357
  - Appointment of Prof. H. G. Sanders as Dean of the Faculty of Agriculture, 357
  - Appointment of E. L. Crossley to the chair of dairying, 358
- University of St. Andrews : Honorary degree of LL.D. conferred on Sir Edward Appleton, Sir Lawrence Bragg, Sir Henry Dale, Sir Alexander Fleming and Prof. Angus Robertson Fulton, 324
- University of Sheffield : Appointment of Dr. D. H. Peacock as lecturer in chemistry, 85
  - Appointment of C. Hulse as lecturer in fuel technology, 85
  - Appointment of H. D. Bush as assistant lecturer in physics, 85
  - Appointment of J. M. Thoday as assistant lecturer in botany and zoology, 85
  - Appointment of Dr. D. B. Leason as research assistant in fuel technology, 85
  - Resignation of Dr. R. Rado as lecturer in mathematics, 85
  - Appointment of Dr. A. S. C. Lawrence as senior lecturer in physical chemistry, 564
  - Appointment of Dr. H. J. Tress as lecturer in glass technology, 564
  - Appointment of H. Graetzer as assistant lecturer in mathematics, 564
  - Appointment of G. H. Jowett as assistant lecturer in statistics in the Department of Mathematics, 564
  - Appointment of J. R. Beattie as assistant lecturer in physics, 564
  - Appointment of Douglas W. Riley as assistant lecturer in chemistry, 564
  - Appointment of H. J. Whiteley as assistant lecturer in pathology, 564
  - Resignation of Dr. J. Sinclair as senior lecturer in mining, 564
  - Resignation of Dr. F. Bielschowsky as cancer research worker in the Department of Pathology under the British Empire Cancer Campaign, 564
  - Appointment of H. Ferrari as lecturer in mining, 745
  - Appointment of Dr. W. Hume-Rothery as honorary lecturer in the Department of Metallurgy, 745
  - Prof. H. N. Green granted the additional title of director of cancer research, 745
  - Resignation of G. E. Cooke as lecturer of civil engineering, 745
  - Resignation of Dr. H. McIlwain as lecturer in biochemistry, 745
- University of Sydney : Appointment of Dr. T. G. Hunter as professor of chemical engineering, 85
- University College of Wales, Aberystwyth : Seventy-fifth anniversary of the, 633
- University College, Cardiff : Appointment of Dr. J. Sinclair to the chair of mining, 564
- University College, Christchurch : Appointment of N. M. MacElwee as professor of electrical engineering, 85

NAME INDEX

University College, Dundee : Appointment of Dr. G. H. Bell to the chair of physiology, 291
University College, Leicester : Appointment of R. L. Goodstein as professor of mathematics, 863
University College, London : Inaugural Lecture (Prof. Herbert Dingle), 108
  Appointment of Prof. W. G. Holford to the University chair of town planning, 462
University College, London, and the British Boot, Shoe and Allied Trades Research Association : Research Fellowship for work on the structure of the human foot, 497
University College, Nottingham : Appointment of Dr. F. E. King as professor of chemistry, 863
University Grants Committee : Application of the Bradford Technical College for recognition as a university college refused, 84
Unna, P. J. H. : Angle of Incidence of the Sun's Rays, 713
Ussing, Dr. Hans H. : Interpretation of the Exchange of Radio-Sodium in Isolated Muscle, 262
Uvarov, Dr. B. P. : The Grasshopper Problem in North America, 857

VACALOPOULOS, Charalambos : Awarded a U.N.E.S.C.O. Fellowship, 706
Vajda, Dr. S. : Technique of the Analysis of Variance, 27
  Science and Technical Education in Germany—Statistical Methods, 724
Vallarta, Prof. Manuel Sandoval, and Arnaiz y Freg, Arturo : The Name of Element 23, 163
Van de Graaff, Dr. R. J. : Awarded the Duddell Medal for 1947 of the Physical Society, 495
Vaswani, Miss S. P. : A Pitfall in Correlation Theory, 405
Vaughan, E. A. : Appointed lecturer in the Department of Social Studies in the University of Leeds, 563
Vavruch, Dr. Ivan : Awarded a U.N.E.S.C.O. Fellowship, 706
Vayssière, Prof. P. : Pests of Stored Foods, 739
Vegetable Research Station : First meeting of the Governing Body, 562
Velden, Van der : Mechanism of Colour Vision, 666
Vendrely, Dr. R. (Tulasne, Dr. R., and) : Demonstration of Bacterial Nuclei with Ribonuclease, 225
Verdoorn, Dr. Frans : Appointed an honorary staff member of the Botanic Gardens, Buitenzorg, 152
Vernon, D. S. F. : Market Research and the Seller, 686
Vesey-Fitzgerald, L. D. E. F. : Appointed senior assistant game warden, Kenya, 745
Veterinary Educational Trust : Formation of a Canine Committee, 394
Vick, Dr. F. A. : Thermionic Emission from Oxide-Coated Cathodes, 725
Vickers, Dr. A. E. J. : Progress in Electron Microscopy, 763
Vickerstaff, Dr. T. : Theory and Practice of Dyeing, 698
Vickery, R. C. : Variation in Density of Cerium Oxide, 830
Victoria, National Museum of : To make an ecological survey of the Snowy River area, 48
Vienna Academy of Sciences (Dr. O. Peczenik), 406 ; (Dr. Robert W. Lawson), 406
Vigoureux, Dr. P. : Piezo-Electricity, *review*, 348
  Absorption of Ultrasonic Waves in Liquids, 914
Vines, R. G. : Properties of Liquid Explosives, 400
Visiting Scientists, Society for : Discussion on Law-making in Science, 530
Vitucci, J. S. (Nord, Prof. J. J., and) : Enzyme Studies on the Mechanism of Wood Decay, 224
  Enzymatic Hydrolysis of Cellulose by *Coniophora cerebella*, 261
Voegtli, Dr. W. (Staehelin, Dr. D., and) : Alloxan Diabetes and Glycogen Phosphorolysis in Rats, 363
Vonberg, D. D. (Ryle, M., and) : Relation between the Intensity of Solar Radiation on 175 Mc./s and 80 Mc./s, 157
Vries, Dr. Hl. de : Mechanism of Colour Vision, 664
Vries, Dr. Hl. de, and Groendijk, H. : Evidence against Spontaneous Emission of Neutrons by Uranium X, 435

WADDINGTON, Prof. C. H. : Recent Progress in Genetics, *review*, 772
Wadia, D. N. : Science in the New India, 253
Wald, Dr. G. : Mechanism of Colour Vision, 665
Walker, Dr. A. G. : Theory of Lie Groups, I (Claude Chevalley), *review*, 854
Walker, Dr. James, and others : Antagonistic Effect of certain Growth-Stimulants of the Tuberculostatic Activity of 5-Amino-2-butoxypyridine, 94
Walker, J. W. (Mayer-Gross, W., and) : Effect of *l*(+)Glutamic Acid in Hypoglycæmia, 334
Walker, Dr. T. K., and others : Detection of Acetic Acid in *A. niger* Growing on a Glucose Medium, 573
Walker, Dr. T. K. (Kaushal, R., and) : Formation of Cellulose by *Acetobacter acetigenum*, 572
Walkinshaw, W., and others : Travelling-Wave Linear Accelerator for Electrons, 351
Wall, P. D., and others : An Ensheathed Rotating Knife for Causing Brain Lesions, 365
Wallis, Dr. T. E. : Textbook of Pharmacognosy, *review* by Dr. W. O. Howarth, 4
Waloff, Z. : Seasonal Breeding and Migrations of the Desert Locust (*Schistocera gregaria*) in Eastern Africa, 67
Walsh, A., and others : Infra-Red Spectrum and Molecular Structure of Phthiocerane, 580
Walsh, Dr. A. D. : Structure of Cyclopropane, 902
Walsh, Dr. R. J., and Montgomery, Miss Carmel M. : A New Human *Iso*-Agglutinin subdividing the *MN* Blood Groups, 504
Walshe, Barbara M. : Feeding Mechanisms of *Chironomus* Larvæ, 474
Walters, Dr. H. V. : Appointed British Council science officer for China, 529 ; work of, 529
Walton, E., and others : Optical Isomers of Amidone, with a Note on *iso*Amidone, 605
Walton, Prof. John : Palæobotany for Everyman, *review*, 734
Wanner, Dr. E. : Annual Seismological Report of the Swiss Observatories, 636
Wansbrough-Jones, Dr. O. H. : Operational Research in War and Peace, 660
Wanstall, P. J. : The Ecology of Ditchling Common, 343
War Office : Appointment of an Advisory Council for the Military College of Science, 48
Warburton, M. F., and others : Hæmagglutinins of the *Haemophilus* Group, 63
Ward, —. : Progress in Nuclear Physics, 493
Ward, A. G. : Rheology of Minerals, 845
Ward, Dr. F. A. : Demonstration Models of Physical Processes, 151
Ward, J. C. (Pryce, Prof. M. H. L., and) : Angular Correlation Effects with Annihilation Radiation, 435
Wardlaw, Prof. C. W. : Control of Banana Wilt Disease, 405
  Experimental Production of a Protostele from a Dictyostele in *Dryopteris aristata*, 539
  Tensile Stress as a Factor in Fern Phyllotaxis, 678
  Co-operation in Botanical Research, 804
Wardrop, A. B., and Preston, Dr. R. D. : Organisation of the Cell Walls of Tracheids and Wood Fibres, 911
Warren, A. G. : Methods of Crack Detection, 557
Waser, Jürg, and Wieland, Dr. K. : Emission Spectrum of Iodine Molecules in the Presence of an Inert Gas, 643
Waterman, Dr. A. T. : Atomic Energy and the Veto, 460
Waterston, J. M. : Appointed senior botanist, Nigeria, 15[illegible]
Watkin, Dr. J. Elphin (Knowles, Frank, and) : A Practical Course in Agricultural Chemistry, second edition, *review*, 553
Watson, Prof. D. M. S. : *Obituary* of Sir Clive Forster-Cooper, 425
Watson, E. L. Grant : Wonders of Natural History, *review*, 775
Watson, Prof. J. A. Scott : Appointed chief scientific and agricultural adviser to the Ministry of Agriculture and Fisheries and director-general of the National Agricultural Advisory Service, 785
Watson, Prof. W. H. : The Physical Principles of Wave Guide Transmission and Antenna Systems, *review* by Dr. R. L. Smith-Rose, 206
Watson-Munro, C. N. : Progress in Nuclear Physics, 493
Watson-Watt, Sir Robert : Operational Research in War and Peace, 660
Watts, Prof. W. W. : *Death* of, 220 ; *obituary* by Prof. P. G. H. Boswell, 355
Weatherall, R. : School Certificate Biology, *review*, 72
  Army Education Courses—Preparation for Marriage, 684
  British Social Hygiene Council International School in Social Biology, 803
  Series of lectures at the International School in Social Biology, 803
Weaver, Elbert Cook, and Foster, Dr. Laurence Standley : Chemistry for our Times, *review*, 142
Webb, Dr. K. R. : Naming the Elements—a Former Suggested Use of 'Plutonium', 164
Weber, Dr. G. : Elected to a Beit Memorial Junior Fellowship for Medical Research, 152
Weddell, Dr. G., and others : Significance of Multiple Innervation of Cutaneous Pain 'Spots' in relation to the Quality of Pain Sensibility, 27
Weil, R. : Mechanical Properties of Metals, 696
Weintroub, S. : Jubilee of the Discovery of the Electron, 776
Weir, Chas. D. : Anodic Behaviour of Mild Steel in Strongly Alkaline Solutions, 259
Weiss, Dr. J. : Electrode Processes, 306
  The Electron Affinity of ClO, 717
Weissenberg, Dr. L. : Rheology of Minerals, 845
Weisz, Olga : Training of X-Ray Crystallographers in Polytechnics and Universities, 30
Weisz, Olga (Perutz, Dr. M. F., and) : Crystal Structure of Human Carboxyhaemoglobin, 786
Welding, Institute of : Election of J. L. Adam as president, 16
  Election of Dr. J. H. Paterson as vice-president, 16
Wells, Dr. A. F. : New Industrial Techniques and Results of X-Ray Crystallography, 31
Wells, Dr. A. Q. : The Murine Type of Tubercle Bacillus (the Vole Acid-Fast Bacillus), 687
Wells, P. A. : Appointed director of education in the International Wool Secretariat, London, 428
Wenley, A. G. : A Description of the Tomb of the Grand Empress Dowager Wên Ming and the Northern Wei Necropolis at Fang Shan, 462
Werner, Prof. A. E. A. : Co-ordination Complexes containing Olefines, 644
West, Miss M. M. : The Public Health Nurse and the Family Unit, 803
Westall, R. G., and others : Displacement Chromatography on Cation-Exchange Materials, 374
Westinghouse (George) Centennial Forum, May 16–18, 1946 (Science and Life in the World, Vol. 1, Science and Civilization ; The Future of Atomic Energy ; Vol. 2, Transportation—a Measurement of Civilization ; Light, Life and Man ; Vol. 3, A Challenge to the World), *review* by W. L. Sumner, 141
Westminster Hospital Medical School : Appointment of Dr. N. F. Maclagan to the University of London chair of chemical pathology, 824
Wexler, Dr. Harry, and others : Unit for Solar Radiation Work, 327
Weyl, Prof. Hermann : Elected a *correspondant* for the Section of Geometry of the Paris Academy of Sciences, 326
Wheeler, Prof. T. S. : Elected president of the Irish Chemical Association, 497
Wheeler, W. F. : Essentials of Biology, *review* by R. Weatherall, 72
Whewell, Dr. C. S. : Fireproofing of Fabrics, *review*, 278
Whiddington, Prof. R. : Progress in Electron Microscopy, 762
White, A. : Function of the Lymphocyte, 845
White, Dr. Leslie A. : The Expansion of the Scope of Science, 743
White, M. H. Gleeson, and others : Chemotherapeutic and other Studies of Typhus, 726
Whitehead, Prof. Alfred North : Essays in Science and Philosophy, *review* by Sir Edmund Whittaker, 415
Whitehead, Dr. T. (Wood, Dr. Conway A., and) : Etiology of Strawberry Virus Diseases, 761
Whiteley, Dr. A. L. : Fundamental Principles of Automatic Regulators and Servo Mechanisms, 340
Whiteley, H. J. : Appointed assistant lecturer in pathology in the University of Sheffield, 564
Whittaker, Sir Edmund : Whitehead's Collected Essays, *review*, 415
Whittingham, Dr. G. : A New Technique for Following the Attack of Metallic Mirrors by Free Radicals, 671

Whittle, Air Commodore F. G. : Awarded the Kelvin Gold Medal for 1947, 564
Wiame, J. M., and others : Physiological Heterogeneity of Metaphosphate in Yeast, 717
Wieland, Dr. K. (Waser, Jürg, and) : Emission Spectrum of Iodine Molecules in the Presence of an Inert Gas, 643
Wiggins, L. F. : Degree of D.Sc. of the University of Birmingham conferred on, 85
Wigglesworth, Dr. V. B. : The Corpus Allatum and the Control of Metamorphosis in Insects, 16
Wightman, Dr. W. P. H. : Science in Scotland, the Work of the Scottish Research Institutions, 252, 341
Wild, A. M. : General Equation for the Serial Dilution Technique in Microbiological Assays, 57
Wilkin, G. A. C. : The Utilization of Carbohydrates, 373
Wilkinson, Dr. D. H. : Progress in Nuclear Physics, 494
Wilkinson, Dr. G. : A New Isotope of Tungsten, 864
Willatts, Dr. E. C. : Problems of Soil and Land Classification, 687
Williams, Dr. David : Title of University of London reader in mining geology conferred on, 462
Williams, Capt. E. Brook : Wind Statistics and their relation to Air Line Operation, 427
Williams, Prof. F. C. : Electronic Servo Simulators, 340
Williams, Dr. Gertrude : Title of University of London reader in social economics conferred on, 326
Williams, Dr. S. E. : Solar Radio-Frequency Noise Fluctuations and Chromospheric Flares, 708
Williams, W. T. : Shock-induced Stomatal Movements, 364
Williamson, Dr. W. T. H. : Appointed lecturer in charge of the Department of Soil Science in the University of Aberdeen, 428
Willmer, Dr. E. N. : Mechanism of Colour Vision, 665
Willmore, P. L. : Seismic Aspects of the Heligoland Explosion, 350
Wilman, H. : Electrode Processes, 306
Wilson, Dr. A. E. : Some Archaeological Problems in South-East England, 343
Wilson, A. H. : Theory and Practice of Dyeing, 700
Wilson, Prof. A. J. C. : Diffraction of X-Rays by the Alloy $AuCu_3$, 304
Wilson, A. R. : Classification, Breeding and Preservation of the Potato, 843
Wilson, G. B. : Meiosis in Bougainvillea, 121
Wilson, H. : Paper for Technical Journals, 636
Wilson, John : Appointed director of research to the British Rayon Research Association, 706
Wilson, R. (Woodhead, D. W., and) : Mach Waves in Shock Wave Systems from Detonating Explosives, 672
Wilson, Prof. W. C. : Operational Research in War and Peace, 661
Wiltshire, Dr. S. P. : Danish Work on *Alternaria* and *Stemphylium*, review, 313
Wiltshire, W. J. : Methods of Crack Detection, 556
Winchester City Museums, 1847–1947 (Frank Cottrill), 253
Winge, Prof. Øjvind : Elected an honorary member of the Genetical Society of Great Britain, 83
Wirth, Dr. Louis : Responsibility of Social Science, 622
Wiseman, Dr. J. D. H. : Piston Core-Sampler, 410
Woerdeman, Prof. M. W., and Raven, Prof. Chr. P. : Experimental Embryology in the Netherlands, 1940–1945, *review*, 626
Wohlfarth, E. P. (Stoner, Prof. E. C., and) : Interpretation of High Coercivity in Ferromagnetic Materials, 650
Wolfrom, M. L. (edited by Pigman, W. W., and) : Advances in Carbohydrate Chemistry, Vol. 2, *review* by Dr. E. G. V. Percival, 208
Women Science Teachers, Association of : Report on Science in Post-Primary Education, 783
Women's Engineering Society (Women's Legion and the) : Foundation of a Scholarship in Aeronautical Engineering for Women, 428
Women's Legion and the Women's Engineering Society : Foundation of a Scholarship in Aeronautical Engineering for Women, 428
Wong, Yung Chow : Degree of D.Sc. of the University of London conferred on, 601
Wood, Dr. : British Needs and Resources of Calories, Protein and Calcium, 701
Wood, Dr. Alex. : Lecture on the History of the Cavendish Laboratory, 704
Wood, Dr. Conway A., and Whitehead, Dr. T. : Etiology of Strawberry Virus Diseases, 761
Wood, Prof. G. L. (edited by) : Australia, its Resources and Development, *review*, 775
Wood, Dr. W. A. : X-Rays in Research and Industry (Dr. H. Hirst), second edition, *review*, 142
Woodhead, D. W. : Velocity of Detonation of a Tubular Charge of Explosive, 644
Woodhead, D. W., and Wilson, R. : Mach Waves in Shock Wave Systems from Detonating Explosives, 672
Wool Secretariat, International : Appointment of P. A. Wells as director of education, 428
Woolcock, W. J. U. : *Death* of, 703
Wooldridge, Prof. S. W. : Problems of Soil and Land Classification, 686
Wooldridge, Dr. W. R. : British Needs and Resources of Calories, Protein and Calcium, 702
Wooster, Dr. W. A. : X-Ray Crystallographers in Industry, 29
  Training of X-Ray Crystallographers in Polytechnics and Universities, 29
Wooster, Dr. W. A., and Macdonald, G. L. : Smears of Titanium Metal, 260
  Inequality of (111) X-Ray Reflexions in Diamond, 500
World Federation of Scientific Workers (J. G. Crowther), 628
  Commemoration of the Tenth Anniversary of the death of Lord Rutherford, 806
World Power Conference : To be held in London in 1950, 564
  Fuel Economy Conference of the (Dr. H. E. Crossley), 740
Wormall, Prof. A., and others : Use of Radioactive Isotopes in Immunological Investigations, 339
Worthington, Dr. E. B. : A Development Plan for Uganda, 172 ; *review* by Prof Walter Fitzgerald, 691
Wrazej, Dr. W. J. : New Industrial Techniques and Results of X-Ray Crystallography, 31
  Structure of Retained Austenite in Plain Carbon Steels, 93
Wright, D. A. : Thermionic Properties of Thoria, 129
  Thermionic Emission from Oxide-Coated Cathodes, 726
Wright, G. M., and others : Mendelian Inheritance in New Zealand Romney Sheep, 646
Wright, Dr. Norman C. : Appointed chief scientific adviser to the Minister of Food, 530, 667 ; work of, 667
  British Needs and Resources of Calories, Protein and Calcium, 702
Wright, Prof. Samson, and others : Physiological Effects of Alkyl Polyphosphates, 760
Wright, Prof. Samson (Chennells, Mary, and) : Central Excitant Action of Diisopropylfluorophosphonate, 503
Wright, Dr. Sewall : Awarded the Daniel Giraud Elliot Medal for 1945 of the U.S. National Academy of Sciences, 169
Wright, T. A., and others : An Ensheathed Rotating Knife for Causing Brain Lesions, 365
Wright, W. A. : Appointed agricultural officer, Sierra Leone/Gambia, 745
Wright, Dr. W. D. : 'Foveal Tritanopia', 647
  Mechanism of Colour Vision, 665
Wunderly, Dr. Ch. : Influence of Hydrotropic Substances on the Sol/Gel Transformation of Blood Plasma *in vitro*, 228
Wyckoff, Dr. Ralph W. G. (Polson, Dr. A., and) : Shape of Hæmocyanin Molecules, 153
Wye College : Five-hundredth Anniversary, 40
  Appointment of M. McGregor to the University of London chair of agriculture, 462
  Establishment of a research centre for hop production problems, 668
Wyk, G. F. van : Critical Moisture Content of Dehydrated Stockfish, 872
Wylie, Dr. A. W. : Coprecipitation of Uranous Sulphate with Rare-Earth Double Sulphates, 830
Wyllie, G. : Qualitative Quanta, *review*, 692
Wyman, Dr. Donald : The Arboretums and Botanical Gardens of North America, *review*, 775
Wynne, C. G. : Chromatic Correction of Wide-Aperture Catadioptric Systems, 91
Wynne-Jones, Prof. W. F. K. : Appointed to the chair of chemistry at King's College, Newcastle-upon-Tyne, 291 ; work of, 291
  Electrode Processes, 306

YABSLEY, D. E., and others : Relative Times of Arrival of Bursts of Solar Noise on Different Radio Frequencies, 256
Yaffe, Dr. L. (Guéron, Dr. J., and) : Formation of Uranium Hydride, 575
Yale University School of Medicine : Sixth Annual Report of the Historical Library, 151
  Report for 1946–47 of the Historical Library, 823
Yang, L. : Electrode Processes, 306
Yates, Dr. F. : Technique of the Analysis of Variance, 472
Yates, H. G., and Catherall, R. : Combination Tones, 198
Yeates, G. K. : Bird Haunts in Southern England, *review* by Frances Pitt, 314
Yeates, N. T. M. : Influence of Variation in Length of Day upon the Breeding Season in Sheep, 429
Younghusband, Eileen L. : Report on the Employment and Training of Social Workers, 137

ZEI, M., (Peczenik, Dr. O., and) : Influence of Hypophyseal Hormone and of Nervous Impulses on the Colour-dress of Hermaphrodite Teleostean Fish, 788
Zernicke, Prof. F. : Diffraction and Optical Image Formation, 394
Zeuthen, Dr. Erik : Respiration and Cell-Division in Eggs of the Sea Urchin, *Psammechinus miliaris*, 577
Zoological Gardens, London : Appointment of George S. Carsdale as assistant superintendent, 326
Zoological Record : The, Vol. 81 (Dr. Edward Hindle), 309
Zootechny, Italian Association for the Progress of : Establishment at Milan, 785
Zuckerman, Prof. S. : The Process of Puberty, *review*, 591
  Operational Research in War and Peace, 661
Zurukzoglu, Dr. St. : Social Psycho-Hygiene, 803
Zweifach, B. W. (Chambers, R., and) : Organisation of the Capillary Circulation, 443
Zworykin, Dr. V. K. : Weather Control, 220

TITLE INDEX

ABNORMAL Reproduction in Woodlice (Dr. Walter E. Collinge), 509
Absolute Values of the Rates of Unimolecular Reactions (Dr. H. Pelzer), 576 ; (N. B. Slater), 576
Absorption in Liquids (Ultrasonic) : A Pulse Method for the Measurement of—Results for Water (J. M. M. Pinkerton), 128
Absorption of Ultrasonic Waves in Liquids (Acoustics Group of the Physical Society discussion on), 913
Absorption Bands of Li_2, Na_2, K_2 and NaK (Dr. R. W. B. Pearse and S. P. Sinha), 159
Absorption Spectra with Polarized Infra-Red Radiation (J. Mann and Dr. H. W. Thompson), 17
Absorption Spectra of Ruby : Raman Spectrum of Alumina and the Luminescence and (Dr. R. S. Krishnan), 26
Accelerated Motion : Relativity of (Dr. D. Meksyn), 834
Accelerating Equipment of the Cavendish Laboratory, Cambridge : The One Million-Volt (Dr. W. E. Burcham), 316
Accelerator for Electrons : Travelling-Wave (D. W. Fry, R. B. R.-S. Harvie, L. B. Mullett and W. Walkinshaw), 351
Accessory Glands and Spermatogenesis : Functional Development of (Dr. D. V. Davies and Dr. T. Mann); 295
Acetic Acid in *A. niger* Growing on a Glucose Medium (I. D. Chughtai, A. A. Pearce and Dr. T. K. Walker), 573
Acetobacter acetigenum : Formation of Cellulose by (R. Kaushal and Dr. T. K. Walker), 572
Acid Production in Saliva/Cane-sugar Solutions (E. Føyn and A. Hobæk), 758
Acid-Alkali Titrations : Mercurochrome as an Indicator in (Dr. J. W. Airan), 88
Acids (Organic) : Partition Chromatography of, on a Paper Sheet Support (J. W. H. Lugg and B. T. Overell), 87
Acoustics : Musical (Conference at Liège on), 765
Acquired Resistance to Quinine in *Plasmodium gallinaceum* : Twofold (Dr. A. Th. Knoppers), 606
Acrogenous Spores in *Verticillium* : Passive Movements of Newly Formed, and some other Genera of the Hyphomycete Fungi (C. J. La Touche), 679
Acrylonitrile : Effect of Gamma- and X-Rays on Dilute Aqueous Solutions of (Dr. F. S. Dainton), 268
Actin : X-Ray Study of (Prof. W. T. Astbury), 388
Action of Salt Solutions on Myosin : Electron Microscope Investigation of the (Prof. Silvio Ranzi), 712
Activation of Copper by Oxidation and Reduction (F. C. Aldred and Dr. F. Happey), 267
Activation of the Transamination between Glutamic Acid and Pyruvic Acid : Optimum *p*H and Temperature, and Energy of (S. Darling), 838
Activities of *l*- and *dl*-Thyroxine : Relative (W. E. Griesbach, T. H. Kennedy and H. D. Purves), 192
Activity of Ants : Individual (Derek Wragge Morley), 122
α-Acyl Hydrazines (Prof. J. Kenner and K. Mackay), 465
Adaptability : Man's (Dr. S. J. F. Philpott), 288
Adenohypophysectomy on the Transfer of Salt across the Frog Skin : Influence of (C. Barker Jørgensen), 872
Adolescent Sterility (Prof. M. F. Ashley-Montagu), *review* by Prof. S. Zuckerman, 591
Adrenalectomized Lactating Rats as compared with Pair-fed Controls : Decrease in the Arginase of the Liver and Mammary Gland in (Dr. S. J. Folley and A. L. Greenbaum), 364
Adrenaline on the Anaerobic Glycolysis of Rat Diaphragm : Effect of Injection of (Dr. J. A. Cohen), 871
Adsorption (Negative) : Calculation of Surface Areas from Measurements of (Dr. R. Kenworthy Schofield), 408
Adsorption of Water Vapour in High-Vacuum Apparatus (Prof. R. G. W. Norrish and K. E. Russell), 57
Adsorption Analysis of Oxidized Insulin (Prof. A. Tiselius and F. Sanger), 433
Adsorption Apparatus and the Separation of Aspartic and Glutamic Acid : A New (Dr. Birger Drake), 602
Adsorption Isotherm of a Photographic Emulsion for Uranyl and Lead Ions (Dr. E. Broda), 231
Adsorption Isotherms from Chromatographic Measurements (Dr. E. Glückauf), 301
Aedes aegypti L. : Further Observations on the Nutritional Requirements of the Larva of (Dr. L. Golberg and Dr. B. De Meillon), 582
Aedes aegypti Feeding on Rabbits receiving Oral 'Gammexane' : Mortality of (P. C. C. Garnham), 156
Aerobiology : Arctic (Prof. Nicholas Polunin, Prof. S. M. Pady and Prof. C. D. Kelly), 876
Aeroplane : D.D.T. and the, in the Control of the Tsetse Fly and Trypanosomiasis in South Africa (Dr. P. J. du Toit), 485
'Aerosporin', an Antibiotic produced by *Bacillus aerosporus* Greer (G. C. Ainsworth, Annie M. Brown and G. Brownlee), 263
Africa, 1927–1945 : Migrations and Breeding of the Red Locust (*Nomadacris septemfasciata*) in (V. Morant), 67
Africa (Eastern) : Seasonal Breeding and Migrations of the Desert Locust (*Schistocera gregaris*) in (Z. Waloff), 67
Africa (South) : Archæological Research in, 393
    D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in (Dr. P. J. du Toit), 485
African Fodder Grass from Central Burma : Record of an (D. Rhind), 195
African Houses : Economic Control of the Relapsing Fever Tick in (W. F. Jepson), 874
African Lakes (East) : Speciation in Cichlid Fishes of (Dr. Ethelwynn Trewavas), 96
Agassiz Medal for 1947 of the Murray Fund of the U.S. National Academy of Sciences awarded to Prof. Felix Andries Vening Meinesz, 169
Age of the Baker's Hole Coombe Rock, Northfleet, Kent (Prof. H. Breuil), 831
Agricultural Chemistry : A Practical Course in (Frank Knowles and Dr. J. Elphin Watkin), second edition, *review*, 553
Agricultural Products and the Chemical Industry (Dr. J. L. Simonsen), 373
Agricultural Products and of Seaweed : Industrial Utilization of (Irish Chemical Association and the Dublin Section of the Royal Institute of Chemistry colloquium on), 373
Agriculture in Britain : Future of (Lord De La Warr), 914
Agriculture in the Caribbean, 562
Agriculture in Malaya, 50
Agriculture in Northern Ireland, 862
Agriculture at the University of Reading, 357
Agriculture and Horticulture : University Teaching in, 151
Air : Highways of the (Royal Geographical Society's exhibition), 863
Air (Outdoor) : Sublimation in (Dr. B. M. Cwilong), 198
Air Line Operation : Wind Statistics and their relation to (Capt. E. Brook Williams), 427
Air Survey : American Methods and Practice in, *review* by Prof. C. A. Hart, 659
Aircraft : 'Flying Wing', 896
Airport : High-Speed Flying and the (Christmas lectures at the Institution of Civil Engineers), 824
Albino Mice : Induced Polycythæmia by *l*-Ascorbic Acid in (Jui-Ming Chen), 681
Albumin Residue revealed by the Serial Cephalin Flocculation Curve : A Non-Specific Resistance Factor in the (Dr. Jack G. Makari), 201
Alcohol Vapour and Argon : Primary Ionization of β-Particles in (Dr. S. C. Curran and J. M. Reid), 866
Aldehyde (Vitamin A) : Synthesis of (Dr. D. A. van Dorp and Dr. J. F. Arens), 189
Alimentary Tract and Associated Glands of the Fowl, *Gallus domesticus* : Cytology of (Dr. K. S. Chodnik), 62
Alkali Halide-Borate Glasses : Constitution of (H. Cole), 191
Alkali Halides : Vibration Spectra of the (Prof. R. S. Krishnan), 711
Alkaline Solutions : Anodic Behaviour of Mild Steel in Strongly (Chas. D. Weir), 259
Alkalis and Strong and Weak Organic Bases : Uptake of Water by Collagen in Solutions of (Dr. J. H. Bowes and R. H. Kenten), 827
Alkaloid Chemistry : An Essay in Correlation arising from (Sir Robert Robinson), 815
Alkyl Polyphosphates : Physiological Effects of (A. S. V. Burgen and C. A. Keele ; Mary Chennells, J. del Castillo, W. F. Floyd, D. Slome and Prof. Samson Wright), 760
Alleles (Self-Sterility) : Number of (Prof. R. A. Fisher), 797
S-Alleles in a Population : Number of (A. J. Bateman), 337
Allium spp, in England : *Sclerotinia Porri* on (James F. H. Cronshey), 798
Alloxan : Effects of Anterior Pituitary Extract and Hypophysectomy on Blood-Sugar Levels after Injection of (Mervyn Griffiths), 758
Alloxan Diabetes and Glycogen Phosphorolysis in Rats (Dr. D. Staehelin and Dr. W. Voegtli), 363
Alloy $AuCu_3$: Diffraction of X-Rays by the (I. G. Edmunds, R. M. Hinde and Dr. H. Lipson), 304 ; (Prof. A. J. C. Wilson), 304
Alloys : War-Time Developments in Metals and (F. C. T.), 308
Alluvium : Effect of Charge in Turbulent Flow in (Sir Claude Inglis), 60
    Turbulent Flow in (Gerald Lacey), 61
Alternaria and *Stemphylium* : Danish Species of (Paul Neergaard), *review* by Dr. S. P. Wiltshire, 313
Alternative Energy Sources for the 'Second Meson' Events : Hypothetical (Dr. F. C. Frank), 525
Alumina : Raman Spectrum of, and the Luminescence and Absorption Spectra of Ruby (Dr. R. S. Krishnan), 26
Aluminium : Growth of 'Stimulated Crystals' and Rate of Nucleation during Recrystallization of (Prof. W. G. Burgers), 398
Alvarenga Prize for 1947 of the College of Physicians of Philadelphia awarded to Dr. Joseph Aronson, 564
America : The Mentally Ill in (Albert Deutsch), *review* by Dr. G. W. T. H. Fleming, 279
America (North) : The Arboretums and Botanical Gardens of (Dr. Donald Wyman), *review*, 775
    The Grasshopper Problem in (Dr. B. P. Uvarov), 857
    Low-Temperature Physics in (Prof. J. F. Allen), 736
American Awards to British Men of Science, 291, 513
American Bison : Occurrence of *Aspergillus fumigatus* Fresen. in the Lung of an (Dr. R. E. Rewell and Dr. G. C. Ainsworth), 362
American Medical Man : An Early Nineteenth Century, *review* by Dr. E. Ashworth Underwood, 38
American Methods and Practice in Air Survey, *review* by Prof. C A. Hart, 659
American Philosophic Addresses, 1700–1900 (edited by Joseph L. Blau), *review* by Prof. A. D. Ritchie, 37
American Philosophy : A History of (Herbert W. Schneider), *review* by Prof. A. D. Ritchie, 37
American Scientific Mission for London, 633
American and British Chemical Societies' Practice : Indexing Practice—Trends in German, (R. Brightman), 615
Amidone : Optical Isomers of, with a Note on *iso*Amidone (R. H. Thorp, E. Walton and P. Ofner), 605
Amines on Seedling Growth : Toxic Effects of Amino-Acids and (Dr. L. J. Audus and Prof. J. H. Quastel), 222
5-Amino-2-butoxypyridine : Antagonistic Effect by Certain Growth-Stimulants of the Tuberculostatic Activity of (H. S. Forrest, Dr. P. D'Arcy Hart and Dr. James Walker), 94
Amino-Acids of Plant Cells : Detection of the Free, by Partition Chromotography (Dr. C. E. Dent, W. Stepka and Prof. F. C. Steward), 682
Amino-Acids and Amines on Seedling Growth : Toxic Effects of (Dr. L. J. Audus and Prof. J. H. Quastel), 222
2-Aminofluorene on Moulds : Action of (Dr. Elisa Morelli and Dr. Giacomo Misler), 21
Ammi majus L. : A Crystalline Principle from (Prof. I. R. Fahmy, H. Abushady, Prof. A. Schönberg and Aly Sina), 468

- Ammocoetes : Effect of Thiourea on the Endostyle of (Miss R. P. Jones), 638
- Ammonia : Reduction of Aniline in (Dr. Arthur J. Birch), 754
- Amplifier : A Low-Pressure, and Electro-pneumatic Converter (Negretti and Zambra, Ltd.), 325
- α-Amylase : Molecular Weight of (Carl-Erik Danielsson), 899
- Amylopectin : Structure of (Prof. Kurt H. Meyer, P. Gürtler and Dr. P. Bernfeld), 900 ; (Sir W. Norman Haworth), 901
  - Structure of Starch—Mode of Attachment of the Side-chains in (T. G. Halsall, Prof. E. L. Hirst, Dr. J. K. N. Jones and A. Roudier), 899
- Anaerobic Glycolysis of Rat Diaphragm : Effect of Injection of Adrenaline on the (Dr. J. A. Cohen), 871
- Anæsthesia (Chloroform) : Discovery of, 668
- Analysis : Elementary Isotopic—Determination of Nitrogen (A. D. Hirshenbaum, S. G. Hindin and A. V. Grosse), 187
  - Ultrafiltration, *review* by Dr. W. J. Elford, 313
- Analysis (Gas) : Physical Methods of (Society of Public Analysts and other Analytical Chemists, Physical Methods Group, discussion on), 441
- Analysis (Spectrochemical) : Index to the Literature on, Part 2, 1940–1945 (American Society for Testing Materials), 563
- Analysis (X-Ray Structure) : Application of the Method of Steepest Descents to (A. D. Booth), 196
- Analysis of Hydrocarbon Gases by Low Temperature Distillation (J. H. D. Hooper), 441
- Analysis of Solutions : Use of Filter Paper Pellets in the Spectrochemical (Prof. N. S. Bayliss and D. J. David), 334
- Analysis for certain Surface-Active Agents : A Rapid Method of (S. R. Epton), 795 : (T. Barr, J. Oliver and W. V. Stubbings), 909
- Analysis of Variance : Technique of the (Dr. S. Vajda), 27 ; (Dr. F. Yates), 472
- Analytical Geology (Dr. S. I. Tomkeieff), 846 ; (A. B. Vistelius), 846
- Analytical Solution of a Four-cusped Wake (Dr. D. N. de G. Allen), 509
- Anatomy (Vertebrate) : Atlas of Outline Drawings for (Prof. Samuel Eddy, Prof. Clarence P. Oliver and Asst. Prof. John P. Turner), *review* by Dr. W. S. Bullough, 813
- Anatomy of the Mammal : Functional (Asst. Prof. W. James Leach), *review* by Dr. N. B. Eales, 210
- Ancient Plants and the World they Lived in (Assoc. Prof. Henry N. Andrews, Jr.), *review* by Prof. John Walton, 734
- Andrade's Creep Law and the Flow of Zinc Crystals (A. H. Cottrell and V. Aytekin), 328
- Angle of Incidence of the Sun's Rays (P. J. H. Unna), 713
- Angular Correlation Effects with Annihilation Radiation (Prof. M. H. L. Pryce and J. C. Ward), 435
- Aniline in Ammonia : Reduction of (Dr. Arthur J. Birch), 754
- Animal with an Open Type of Circulation : Excessive Hydration in an (A. E. Needham), 755
- Animal Cancer : Plant Tumours and (R. S. de Ropp), 780
- Animal Diseases and Human Welfare (Dr. G. Lapage), 237
- Animal Fodder : Trees and Shrubs as, 862
- Animal Nutrition (Prof. Leonard A. Maynard), second edition, *review* by Dr. D. P. Cuthbertson, 854
- Animal Origin : Crude Drugs and other Raw Materials of Vegetable and, *review* by Dr. W. O. Howarth, 4
- Animal Production : Grassland and (British Grassland Society and the British Society of Animal Production joint meeting on), 249
- Animals of New Zealand : Native (A. W. B. Powell), *review* by T. H. Hawkins, 734
- Animals (Lower) : Relation of Diseases of the, to Human Welfare (New York Academy of Sciences, Section of Biology, conference on), 237
- Annealing Temperature and Hardness of Tantalum (Prof. J. Neill Greenwood and R. H. Myers), 675
- Annihilation Radiation : Angular Correlation Effects with (Prof. M. H. L. Pryce and J. C. Ward), 435
- Annual Register for the Year 1946 (edited by H. T. Montague Bell), *review*, 735
- Anode Phenomena in Molten Electrolytes (A. J. Rudge, W. N. Howell and H. Hill), 504
- Anodic Behaviour of Mild Steel in Strongly Alkaline Solutions (Chas. D. Weir), 259
- Anomaloscope Matching on Viewing Distance or Field Size : Dependence of (R. G. Horner and E. T. Purslow), 23 ; (Dr. J. H. Shaxby), 24 ; (Prof. H. Hartridge), 831
- *Anopheles* : Salivary Gland Chromosomes of (Dr. Guido Frizzi), 226
- Antagonism between Curare and the Potassium Ion (J. P. Quilliam and Dr. D. B. Taylor), 603
- Antagonistic Effect by certain Growth-Stimulants of the Tuberculostatic Activity of 5-Amino-2-butoxypyridine (H. S. Forrest, Dr. P. D'Arcy Hart and Dr. James Walker), 94
- Antartic Leeches : Two New (August Brinkmann, Jun.), 756
- Antenna Systems : The Physical Principles of Wave Guide Transmission and (Prof. W. H. Watson), *review* by Dr. R. L. Smith-Rose, 206
- Antennae, an Introduction to their Theory (J. Aharoni), *review* by Dr. H. G. Booker, 277
- Anterior Lobe of the Pituitary : A New Blood-Pressure Principle of the (Dr. Hans Hase), 787
- Anterior Pituitary Extract and Hypophysectomy on Blood-Sugar Levels after Injection of Alloxan : Effects of (Mervyn Griffiths), 758
- Anthropological Approach in Social Science (Prof. C. Daryll Forde), 286
- Anthropological and Archæological Work in India, 669
- Antibacterial Principle of the Radish (*Raphanus sativus*) : Raphanin, an (Prof. George Ivánovics and Stephan Horváth), 297
- Antibiotic, Penicillic Acid : Synthesis of the (R. A. Raphael), 261
- Antibiotic produced by *Bacillus aerosporus* Greer : 'Aerosporin', an (G. C. Ainsworth, Annie M. Brown and G. Brownlee), 263
- Antibiotics : Penicillin and other (British Association, Sections B (Chemistry), I (Physiology) and K (Botany), symposium on), 554
- Antibiotics by *Fusaria* : Production of (A. H. Cook, S. F. Cox, T. H. Farmer and M. S. Lacey), 31
- *Antigastra* (Lepidoptera–Pyralidæ) Attack : Relation of Total Soluble Solids in the Cell Sap of *Sesamum* Species to the Degree of Susceptibility and Resistance to (Dr. S. Mukherji), 95
- Antigen, 'Jobbins' : A New Blood Group (B. E. Gilbey), 362
- Antiquity of Pegmatites from Manitoba : Geological Age—the Extreme (Dr. L. H. Ahrens), 874
- Antiseptics : Assay of Cation-Active (Dr. M. A. Phillips), 55
- Antitubercular Activity of Diphenyl Ethers and related Compounds (Dr. Vincent C. Barry, L. O'Rourke and D. Twomey), 800
- Ants : Individual Activity of (Derek Wragge Morley), 122
- Ape-man (Male Sterkfontein) : Jaw of the (Dr. R. Broom and J. T. Robinson), 153
- Ape-man, *Plesianthropus* : Further Remains of the Sterkfontein (Dr. R. Broom and J. T. Robinson), 430
- Aphid Vectors of European Raspberry Viruses (C. H. Cadman and A. R. Hill), 837
- Apparatus for Preparative Electrophoresis (Dr. J. A. V. Butler and Miss J. M. L. Stephen), 469
- Appeal of Museums, *review* by T. H. Hawkins, 734
- Aquatic Plants : Diffusion of Dissolved Substances through Thalli and Leaves of (Prof. E. Steemann Nielsen), 376
- Aqueous Solutions of Acrylonitrile : Effect of Gamma- and X-Rays on Dilute (Dr. F. S. Dainton), 268
- Arboretums and Botanical Gardens of North America (Dr. Donald Wyman), *review*, 775
- Archæological Problems in South-East England : Some (Dr. A. E. Wilson), 343
- Archæological Research in South Africa, 393
- Archæological Work in China, 462
- Archæological Work in Greece, 601
- Archæological Work in India : Anthropological and, 669
- Arctic Aerobiology (Prof. Nicholas Polunin, Prof. S. M. Pady and Prof. C. D. Kelly), 876
- Areas (Surface) : Calculation of, from Measurements of Negative Adsorption (Dr. R. Kenworthy Schofield), 408
- Arginase of the Liver and Mammary Gland in Adrenalectomized Lactating Rats as compared with Pair-fed Controls : Decrease in the (Dr. S. J. Folley and A. L. Greenbaum), 364
- Argon : Primary Ionization of β-Particles in Alcohol Vapour and (Dr. S. C. Curran and J. M. Reid), 866
- Arithmetic : A New (A. W. Siddons, K. S. Snell and E. H. Lockwood), Parts 1, 2 and 3, and Notes and Answers, *review*, 279
- Army Education Courses—Preparation for Marriage (R. Weatherall), 684
- Arrival of Bursts of Solar Noise on Different Radio Frequencies : Relative Times of (Ruby Payne-Scott, D. E. Yabsley and J. G. Bolton), 256
- Art of Astrology : The Royal (Robert Eisler), *review* by Joshua C. Gregory, 276
- Art and Industry : Physical Science in (Dr. E. G. Richardson), second edition, *review* by F. Ian G. Rawlins, 315
- Artificial Insemination of Livestock : Stockbreeding and the (V. K. Milovanov and I. I. Sokolovskaya), translated by Dr. A. G. Morton, *review* by John Hammond, 209
- Artificial Mesons : Cross-Sections for Production of (Cécile Morette and Dr. W. H. Peng), 59
- Artificial Radioactivity : The Application of, to Biology and Medicine (Dr. John H. Lawrence), 51
- Arts (Creative) : Science and the (W. B. Honey), *review* by F. Ian G. Rawlins, 418
- Ascorbic Acid Content of Whale's Milk (Dr. Michael Begg), 430
- *l*-Ascorbic Acid in Albino Mice : Induced Polycythæmia by (Jui-Ming Chen), 681
- Aspartic and Glutamic Acid : A New Adsorption Apparatus and the Separation of (Dr. Birger Drake), 602
- *Aspergillus fumigatus* Fresen. in the Lung of an American Bison : Occurrence of (Dr. R. E. Rewell and Dr. G. C. Ainsworth), 362
- *Aspergillus niger* Growing on a Glucose Medium : Detection of Acetic Acid in (I. D. Chughtai, A. A. Pearce and Dr. T. K. Walker), 573
- Assay of Cation-Active Antiseptics (Dr. M. A. Phillips), 55
- Assay Procedure : A Modified Microbiological (A. L. Bacharach), 640
- Assays (Microbiological) : General Equation for the Serial Dilution Technique in (A. M. Wild), 57
- Assessing the Total Number of Viable Bacteria in Raw and Heated Milk : Limitations of the Colony Count Test for (C. S. Morris and M. A. Edwards), 434
- Assimilation Affinity in *Staphylococcus aureus* : Correlation between Penicillin Resistance and (Dr. Ernest F. Gale), 407
- Astacene in the Brown Trout (D. M. Steven), 507
- Asteroid : An Unusual, 898
- Astrology : The Royal Art of (Robert Eisler), *review* by Joshua C. Gregory, 276
- Astronomical Chart : The Soochow (W. Carl Rufus and Hsing Chih Tien), *review*, 279
- Atlantic Flight : Automatic Control on, 461
- Atlas of Bacteriology (Dr. R. Cranston Low and T. C. Dodds), *review* by Dr. James Marshall, 349
- Atlas of Histopathology of the Skin (Prof. G. H. Percival, Prof. A. Murray Drennan and T. C. Dodds), *review*, 553
- Atmosphere (Earth's) : The Radiations from the (Prof. S. Chapman and D. R. Bates), 250
- Atmosphere (Lower) : Psychrometric Observations in the (Richard A. Craig), 5[illegible]6
- Atmospheric Oscillations : Microseisms and (Ernest Tillotson), 321
- Atmospheric Turbulence (Royal Astronomical Society Geophysical discussion on), 859
- Atomic Dimension : Optical Rotatory Power and (Dr. W. Gerrard and W. Lessing), 467
- Atomic Energy : Bibliography of (M. C. Leikend), 426
  - Control of, 655 ; (Dr. E. H. S. Burhop), 910
  - International Control of (Association of Scientific Workers discussion on), 426
  - International Control of, 460
  - Metallurgical Problems involved in the Generation of Useful Power from (Sir Wallace Akers), 182
  - Release of Information on, 445
  - Research in Germany on the Technical Application of (Prof. W. Heisenberg), 211
  - A Travelling Train Exhibition on (Atomic Scientists' Association), 358, 668
  - What is (Dr. K. Mendelssohn), *review* by Prof. P. B. Moon, 315
- Atomic Energy for Peaceful Purposes (Prof. G. J. Sizoo), 740

Atomic Energy and the Veto (Atomic Scientists' Association discussion on), 460
Atomic Physics (G.-B. Instructional, Ltd., film on), 822
Attachment of the Side-chains in Amylopectin : Structure of Starch—Mode of (T. G. Halsall, Prof. E. L. Hirst, Dr. J. K. N. Jones and A. Roudier), 899
Attack of Metallic Mirrors by Free Radicals : A New Technique for Following the (Dr. G. Whittingham), 671
Audibility of Members of Parliament, 185
Aurora Borealis : Radio Echoes from the (Dr. A. C. B. Lovell, J. A. Clegg and C. D. Ellyett), 372
Aurorae : Emission Spectra of the Night Sky and (Royal Society, Gassiot Sub-Committee B, conference on), 16
Auroras (Polar) : Interpretation of Radio Echoes from (N. Herlofson), 867
Austenite (Retained) : Structure of, in Plain Carbon Steels (Dr. W. J. Wrazej), 93
Australia : Rainfall Records of, 393
  Special Libraries in, 897
Australia, its Resources and Development (edited by Prof. G. L. Wood), *review*, 775
Automatic Control on Atlantic Flight, 461
Automatic Regulators and Servo Mechanisms (Institution of Electrical Engineers convention on), 340
Autoradiograph Technique (Dr. S. R. Pelc), 749
Autoradiography of Single Cells (S. T. Bayley), 193
Autotrophic Growth of Sulphate-reducing Bacteria (K. R. Butlin and M. E. Adams), 154
Autumn Calvings : Influence of Climatic Conditions on (Richard Phillips and J. L. Davies), 429
l'Avenir dans la vie économique : Les réserves et la régulation de (Pierre Massé), I, Avenir déterminé, *review* by Charles F. Carter, 383
Avenir aléatoire (Pierre Massé), *review* by Charles F. Carter, 383
Avitaminosis in Micro-organisms : Hyper- and (Dr. M. N. Meissel), 269
Azotobacter : Microbiological Oxidation of Cholesterol with (J. Horváth and A. Krámli), 639

BACILLUS *aeroporus* Greer : 'Aerosporin', an Antibiotic produced by (G. C. Ainsworth, Annie M. Brown and G. Brownlee), 263
Bacillus megartherium Bacteriophage : Morphology of (T. A. McLauchlan, Elna M. Clark and F. W. Boswell), 755
Bacteria : Electron Microscopy of (E. M. Brieger, G. R. Crowe and Dr. V. E. Cosslett), 864
Bacteria (Citrate-non-Utilizing) : Utilization of Citric Acid by some So-called (Dr. Iwo Lominski, N. S. Conway, E. N. Harper and J. Basil Rennie), 573
Bacteria (Dried) : X-Ray induced Mutations in (Miss P. Devi, Dr. G. Pontecorvo and Dr. C. Higginbottom), 503
Bacteria (Sulphate-reducing) : Autotrophic Growth of (K. R. Butlin and M. E. Adams), 154
Bacteria in Raw and Heated Milk : Limitations of the Colony Count Test for Assessing the Total Number of Viable (C. S. Morris and M. A. Edwards), 434
Bacterial Catalase : Crystalline (Dr. Denis Herbert and Audrey Jane Pinsent), 125
Bacterial Cell : The Chemical Kinetics of the (Prof. C. N. Hinshelwood), *review* by Dr. J. Monod, 105
Bacterial Nuclei with Ribonuclease : Demonstration of (Dr. R. Tulasne and Dr. R. Vendrely), 225
Bacteriology : Atlas of (Dr. R. Cranston Low and T. C. Dodds), *review* by Dr. James Marshall, 349
Bacteriology in the Kitchen (Dr. Irene Hutchinson), 50
Bacteriology of Lakes and Streams : Some Aspects of the (Dr. C. B. Taylor), 584
Bacteriology of Water (Society for Applied Bacteriology symposium on), 583
Bacteriophage (*B. megatherium*) : Morphology of (T. A. McLauchlan, Elna M. Clark and F. W. Boswell), 755
Bacteriostatic Red Pigment produced by a Strain of the *Penicillium nigricans-janczewskii* Series : A Fungistatic and (P. J. Curtis and J. F. Grove), 574
Baker's Hole Coombe Rock, Northfleet, Kent : Age of the (Prof. H. Breuil), 831
B.A.L. : Nephrotoxic and Renotropic Effects of Lead on White Rats and its Prevention by (Dr. Hugo Chiodi and Rodolfo A. Sammartino), 680
Banana Wilt Disease : Control of (Prof. C. W. Wardlaw), 405
Barium Titanate : Curie Point of (M. G. Harwood, P. Popper and D. F. Rushman), 58
  Dielectric Properties of Single Crystals of (J. K. Hulm), 127
Barium Titanate Crystals (H. F. Kay and R. G. Rhodes), 126
Barley : Abnormal Flower Development in, involving Sex Reversal (Prof. F. G. Gregory and O. N. Purvis), 221
Basques : The Blood Groups of the (Dr. A. E. Mourant), 505
Beaumont's (William) Formative Years, Two Early Notebooks, 1811–1821 (edited by Genevieve Miller), *review* by Dr. E. Ashworth Underwood, 38
Beetle from Trinidad into Mauritius to Control *l'herbe Conde* (*Cordia macrostachya*): Introduction of a (Dr. S. Maulik), 194
Behaviour in *Luzula purpurea* Link : Chromosome Number and (Nydia Malheiros and Duarte de Castro), 156
Beit Memorial Fellowships for Medical Research, 152
Bending on Selenium Rectifier Disks : Effect of (Dr. P. Selényi and Nicholas Székely), 197, *erratum*, 326
Bending Tests and Signification : Upper Yield Point—Occurrence in (Dr. Carl Benedicks and Roman Skorski), 399
Benzcinnolines : Phenazines and (Mrs. P. Z. Slack and R. Slack), 437, *erratum*, 497
Benzene Hexachloride in the Blood of Cattle : Determination of (F. Barlow), 719
Benzene Sulphonates (Zinc and Magnesium): Crystal Structures of (J. M. Broomhead and A. D. I. Nicol), 795
Benziminazoles related to Paludrine (R. M. Acheson, Dr. F. E. King and P. C. Spensley), 53
Bessel Functions of the First Kind of Orders Zero and One : Tables of the (Staff of the Computation Laboratory, Harvard University), *review* by Prof. W. G. Bickley, 773
Bessel Functions of the First Kind of Orders Two and Three : Tables of the (Staff of the Computation Laboratory, Harvard University), *review* by Prof. W. G. Bickley, 773
Bessel Functions of the First Kind of Orders Four, Five and Six : Tables of the (Staff of the Computation Laboratory, Harvard University), *review* by Prof. W. G. Bickley, 773
Bessel Functions of the First Kind of Orders Seven, Eight and Nine : Tables of the (Staff of the Computation Laboratory, Harvard University), *review* by Prof. W. G. Bickley, 773
β-Particles in Alcohol Vapour and Argon : Primary Ionization of (Dr. S. C. Curran and J. M. Reid), 866
β- and γ-Radiation from U^{239} and Np^{239} (Prof. Hilding Slätis), 579
Betatron (20-MeV.) : Some Experiments with Fast Electrons and Positrons produced by a (W. Bosley, Dr. J. D. Craggs and W. F. Nash), 790
Bilateral Nephrectomy in the Rat : Hypertension after (E. Braun-Menéndez and Prof. U. S. v. Euler), 905
Bilirubin in the Umbilical Blood as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn : Determination of (Dr. A. Sadowski, Y. M. Bromberg and A. Brzezinski), 192
Biochemistry of Cancer (Jesse P. Greenstein), *review* by Prof. F. Dickens, 241
Biochemistry of *Escherichia coli* and the Production of Penicillinase (Dr. Luigi Gorini and Annamaria Torriani), 332, *errata*, 394
Biological Function of Phosphate in Enzymatic Syntheses : Aspects of the (Dr. Herman M. Kalckar), 143
Biological Significance of Nucleic Acid, *review* by N. W. Pirie, 852
Biologie professées au Collège de France : Leçons de chimie physique appliquée à la (Prof. J. Duclaux), 14, Ultrafiltration, II. Partie théorique et applications, *review* by Dr. W. J. Elford, 313
Biology : Essentials of (W. F. Wheeler), *review* by R. Weatherall, 72
  Introductory, *review* by A. S., 853
  School Certificate, *review* by R. Weatherall, 72
  Water Supply and (Prof. W. H. Pearsall), 176
Biology in Education (British Social Hygiene Council conference on), 785
Biology and Juvenile Delinquency (Dr. E. R. Frey), 803
Biology for Medical Students (C. C. Hentschel and Dr. W. R. Ivimey Cook), fourth edition, *review* by A. S., 853
Biology and Medicine : The Application of Artificial Radioactivity to (Dr. John H. Lawrence), 51
Bird (Largest Known) : Weight of the (Dean Amadon), 743
Bird Haunts in Southern England (G. K. Yeates), *review* by Frances Pitt, 314
Birds : British Diving, *review* by Dr. E. Hindle, 693
  British Sea (C. A. Gibson-Hill), *review* by R. M. Lockley, 591
  The Camera and, *review* by Frances Pitt, 314
  Oceanic, *review* by R. M. Lockley, 591
  Sun-Bathing by (John Gibb), 785
Birds of Pagham Harbour : Some Interesting (S. J. Teideman), 343
Bi^{3+} : Hydrolysis of, Oxygen Bridging—a New Type of Ionic Equilibrium (Fredrik Granér and Dr. Lars Gunnar Sillén), 715
Bison (American) : Occurrence of *Aspergillus fumigatus* Fresen. in the Lung of an (Dr. R. E. Rewell and Dr. G. C. Ainsworth), 362
Bituminous Materials : Soils, Concrete and, *review*, 518
Biuret Reaction of Proteins and the Two-Standard Colorimetry : An Improved (Dr. A. Sols), 89
Blackett's Formula : Universal Constants in (H. Y. Tzu), 746
Blackett's Fundamental Theory of the Earth's Magnetic Field (A. L. Hales and D. I. Gough), 746
Blood (Insects') : Fructose and the Reducing Value of (L. Levenbook), 465
Blood (Umbilical) : Determination of Bilirubin in the, as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn (Dr. A. Sadowski, Y. M. Bromberg and A. Brzezinski), 192
Blood of Cattle : Determination of Benzene Hexachloride in the (F. Barlow), 719
Blood Group Antigen, 'Jobbins' : A New (B. E. Gilbey), 362
Blood Groups *A* and *O* Specificity in Commercial Fluid Hog Stomach Extract : Persistence of a Substance with (M. E. Folan), 790
MN Blood Groups : A New Human *Iso*-Agglutinin subdividing the (Dr. R. J. Walsh and Miss Carmel M. Montgomery), 504
MN Blood Groups in Man : Subdivisions of the (Ruth Sanger and Dr. R. R. Race), 505
Blood Groups (Human) : Dominance and Recessiveness in the (Dr. A. E. Mourant), 353
Blood Groups of the Basques (Dr. A. E. Mourant), 505
Blood Plasma *in vitro* : Influence of Hydrotropic Substances on the Sol/Gel Transformation of (Dr. Ch. Wunderly), 228
Blood-Pressure Principle of the Anterior Lobe of the Pituitary : A New (Dr. Hans Hase), 787
Blood-Sugar Levels after Injection of Alloxan : Effects of Anterior Pituitary Extract and Hypophysectomy on (Mervyn Griffiths), 758
Blow-fly (*Calliphora erythrocephala*) : A Sex-linked and Sex-limited White-eyed Mutation of the (Dr. P. Tate), 361
Body Weight in Man : Brain and (Prof. E. W. Count), 805
Bond Formation by Olefins : Co-ordinate (L. Bateman), 56
Bond-Strengths of Methyl-Iodine and Methyl-Magnesium (Prof. A. R. Ubbelohde and H. Mackle), 303
Bone Marrow Cultures : Maturation of Megaloblasts in (Prof. St. Rusznyák, S. Löwinger and L. Lajtha), 757
Books : Import of Scientific and Technical, 705
  Recent Scientific and Technical, Supp. ii, July 26 ; Supp. ii, August 30 ; Supp. ii, September 27 ; Supp. iii, October 25 ; Supp. ii, November 29 ; Supp. ii, December 27
  Scientific and Technical, 448
Books for Germany : British, 704
Botanical Expedition to Nigeria, 785
Botanical Gardens of North America : The Arboretums and (Dr. Donald Wyman), *review*, 775
Botanical Research : Co-operation in (Prof. C. W. Wardlaw), 804
  Co-operation versus Isolation in (Dr. I. W. Bailey), 804
Botany at McGill University, 600
Botany of the Wild and Cultivated Rices (Dr. D. Chatterjee), 234
Botrytis Fabae Sardiña in England : Occurrence of (L. Ogilvie and M. Munro), 96
Bougainvillea : Meiosis in (G. B. Wilson), 121

Boys (Charles Vernon) Prize for 1947 of the Physical Society awarded to Dr. C. F. Powell, 495, 821
Brain : Phylogenesis of the Perivascular Spaces of the (L. Bakay, jun.), 789
Brain and Body Weight in Man (Prof. E. W. Count), 805
Brain Lesions : An Ensheathed Rotating Knife for Causing (Dr. P. Glees, P. D. Wall and T. A. Wright), 365
Brain Weights : Formulæ and (Dr. Donald Sholl), 805
Bread : Milk, Tinned Foods and (Royal Sanitary Institute, Food and Nutrition Section, and the Society of Chemical Industry, Food Group, joint meeting on), 307
Breeding of the Moustached Warbler in Britain (R. A. Hinde and A. S. Thom), 636
Breeding Season in Sheep : Influence of Variation in Length of Day upon the (N. T. M. Yeates), 429
Brest Explosion : Recordings at Kew of the (J. M. Stagg), 184
Bridges : Principles of (Strip Slide No. 47/1), 393
Brighton : Local Geology as affecting the Water Supply of (F. Needham Green), 343
Britain : Breeding of the Moustached Warbler in (R. A. Hinde and A. S. Thom), 636
  The Evolution of Secondary Education in (Lynda Grier), 289
  Future of Agriculture in (Lord De La Warr), 914
  Hop Research in, 668
  Immigration into, of Continental Butterflies, 359
  Land Utilization in, 809
  School Broadcasting in (Richard Palmer), *review*, 774
  Use of the Land in, 515
  See *also under* Great Britain
Britain in 1955 (Special issue of *Future*), 824
Britain Feed Herself ? : How Far can, 700
British Books for Germany, 704
British Butterflies, *review* by Prof. G. D. Hale Carpenter, 278
British Chemical Societies' Practice : Indexing Practice—Trends in German, American and (R. Brightman), 615
British Chemistry : A Century of (Dr. F. Sherwood Taylor), 84
  The Development of, *review* by Prof. John Read, 657
British Chemists (edited by Alexander Findlay and William Hobson Mills), *review* by Prof. John Read, 657
British Colonial Development, 171
British Colonial Territories : Forestry in, 764
British Divers : Haunts of (Niall Rankin), *review* by Dr. E. Hindle, 693
British Dyestuffs, 528
British Empire : Universities of the (Congress of the), 51
British Families Education Service in Germany (F. J. Downs), 147
British Folliculinidæ (Ciliata, Heterotricha), (R. R. Fowell), 28
British Forest Trees, *review* by Prof. H. G. Champion, 106
British Industry : Scientific and Industrial Research in (Federation of British Industries), 770
British Men of Science : American Awards to, 291, 513
British Needs and Resources of Calories, Protein and Calcium (Nutrition Society conference on), 700
British Scientific Societies (Royal Society to compile a list of), 898
British Sea Birds (C. A. Gibson-Hill), *review* by R. M. Lockley, 591
British Universities : Students in, 861
British-Kenya Miocene Expedition, 1947 (Prof. W. E. Le Gros Clark), 891
Broadcasting in Britain : School (Richard Palmer), *review*, 774
Bronze Star Medal awarded by the Government of the United States to Capt. B. R. S. Dalton and Lieut.-Colonel H. F. Jones, 513
Brown Trout : Astacene in the (D. M. Steven), 507
Buchanan Medal for 1947 of the Royal Society awarded to Sir Edward Mellanby, 704, 840
Buckland Foundation Lecture (J. W. Menzies), 33
Built Before the Flood (H. S. Bellamy), revised edition, *review* by G. H. S. Bushnell, 852
Burma : The Teak Forests of (Prof. E. P. Stebbing), 818
Burma (Central) : Record of an African Fodder Grass from (D. Rhind), 195
Bursts of Solar Noise on Different Radio Frequencies : Relative Times of Arrival of (Ruby Payne-Scott, D. E. Yabsley and J. G. Bolton), 256
Butalastic Polymers (Frederick Marchionna), *review* by Prof. H. W. Melville, 851
Butterflies : British, *review* by Prof. G. D. Hale Carpenter, 278
  Immigration into Britain of Continental, 359
Butterfly Lives (S. Beaufoy), *review* by Prof. G. D. Hale Carpenter, 278

CADMIUM Crystals : Thermal Hardening of (Dr. C. L. Smith), 466
Calcium : British Needs and Resources of Calories, Protein and (Nutrition Society conference on), 700
Calculating Machines (Prof. D. R. Hartree), *review*, 142
Calculation of Surface Areas from Measurements of Negative Adsorption (Dr. R. Kenworthy Schofield), 408
Calculus from a Hippopotamus : Identification of a (Dr. F. A. Bannister, Dr. M. H. Hey and Dr. K. P. Oakley), 470
Calliphora erythrocephala : A Sex-linked and Sex-limited White-eyed Mutation of the Blow-fly (Dr. P. Tate), 361
Calvings (Autumn) : Influence of Climatic Conditions on (Richard Phillips and J. L. Davies), 429
Calories, Protein and Calcium : British Needs and Resources of (Nutrition Society conference on), 700
Camera and Birds : The, *review* by Frances Pitt, 314
Canada : Mineral Production of, 846
Canadian Mineral Industry in 1945, 846
Cancer : Biochemistry of (Jesse P. Greenstein), *review* by Prof. F. Dickens, 241
  Cosmic Rays and (Dr. Frank H. J. Figge), 823
Cancer (Animal) : Plant Tumours and (R. S. de Ropp), 780
Cancer Strains of Mice (High- and Low-Breast-) : Electron Microscope Studies of Normal and Malignant Tissues of (Prof. R. D. Passey, Dr. L. Dmochowski, Prof. W. T. Astbury and Dr. R. Reed), 565
Cancerous and Non-Cancerous Lipoids : Fluorescence of (H. S. Penn and Prof. Joseph Kaplan), 18
Canned Foods : Infected Cooling Water and its Effect on the Spoilage of (T. E. Bashford), 584
Capillaries : Cushion Cells in Retinal Pre-capillaries and (Prof. Arnold Loewenstein), 229
Capillary Circulation : Organisation of the (R. Chambers and B. W. Zweifach), 443
Carbohydrate Chemistry : Advances in (edited by W. W. Pigman and M. L. Wolfrom), Vol. 2, *review* by Dr. E. G. V. Percival, 208
Carbohydrate Metabolism (Prof. Samuel Soskin and Dr. Rachmiel Levine), *review* by Prof. J. H. Quastel, 107
Carbohydrates : Mechanism of Enzyme Specificity in the Domain of (Dr. A. Gottschalk), 113
  The Utilization of (Prof. E. L. Hirst), 373
Carbon (Solid) : Reaction of Hydrogen Atoms with (Prof. G. M. Harris and A. W. Tickner), 871
Carbon Compounds : The Development of Electrochemical Theories of the Course of Reactions of (Sir Robert Robinson), 245
C/D-Ring Union in the Oestrogenic Hormones : Nature of the (Dr. C. W. Shoppee), 64
C—H Bond Energy in Toluene and Xylenes (Dr. M. Szwarc), 403
Carbon Steels : Structure of Retained Austenite in Plain (Dr. W. J. Wrazej), 93
Carborundum : Preparation of Colourless (R. Iley and Prof. H. L. Riley), 468
Carboxyhæmoglobin (Human) : Crystal Structure of (Dr. M. F. Perutz and Olga Weisz), 786
Carcinogenesis : Chemical (Prof. J. W. Cook), 375
Carcinogenesis (Chemical) : Physico-Chemical Aspects of (William Anderson), 892
Carcinogenesis (Experimental) : Risk of Contamination in (Wm. Anderson), 338
Carcinogenic Activity of Preparations Rich in Cholesterol (Dr. I. Hieger), 270
Caribbean : Grain Crops in the, 562
  Soil Surveys in the, 634
Carotenoid Pigmentation of Trout (D. M. Steven), 540
Carty (John J.) Medal for 1947 of the U.S. National Academy of Sciences awarded to Dr. Ross G. Harrison, 169
ρ Cassiopeiæ : Spectrum of (Dr. A. D. Thackeray), 370
Cat : Dissection of the, *review* by Dr. N. B. Eales, 210
Catadioptric Systems : Chromatic Correction of Wide-Aperture (C. G. Wynne), 91
Catalase : Crystalline Bacterial (Dr. Denis Herbert and Audrey Jane Pinsent), 125
Catalase and Hydrogen Peroxide : Reaction between (Dr. P. George), 41
Catalysts : Friedel-Crafts, in Polymerization—Kinetic Measurements and the Role of Water (Prof. R. G. W. Norrish and K. E. Russell), 543
Catalysts (Friedel-Crafts) : Polymerization of Olefins by (Dr. A. G. Evans, G. W. Meadows and Prof. M. Polanyi), 869
Cathode Ray Oscillograph : Application of the, to Measurements of Short Life-Periods of Radioactive Sources (Dr. S. Rowlands), 191
Cathode Ray Oscillograph for Studying the Near Infra-Red Solar Spectrum : Use of the (A. U. Momin), 130
Cathodes (Oxide-Coated) : Thermionic Emission from (Electronics Group of the Institute of Physics summer meeting on), 725
Cation-Active Antiseptics : Assay of (Dr. M. A. Phillips), 55
Cation-Exchange Materials : Displacement Chromatography on (J. R. Bendall, S. M. Partridge and R. G. Westall), 374
Cattle : Determination of Benzene Hexachloride in the Blood of (F. Barlow), 719
Cavity (Resonant) : Flow of Smoke through a Hole in (F. W. Simpson), 93
Cell (Bacterial) : The Chemical Kinetics of the (Prof. C. N. Hinshelwood), *review* by Dr. J. Monod, 105
Cell Division in Eggs of the Sea Urchin, *Psammechinus miliaris* : Respiration and (Dr. Erik Zeuthen), 577
Cell Sap of *Sesamum* Species : Relation of Total Soluble Solids in the, to the Degree of Susceptibility and Resistance to *Antigastra* (Lepidoptera—Pyralidæ) Attack (Dr. S. Mukherji), 95
Cell Walls of Tracheids and Wood Fibres : Organisation of the (A. B. Wardrop and Dr. R. D. Preston), 911
Cells : Autoradiography of Single (S. T. Bayley), 193
  Cushion, in Retinal Pre-capillaries and Capillaries (Prof. Arnold Loewenstein), 229
Cells (Chromatolytic Nerve) : Osmophilic Granules in (Dr. P. Glees), 194
Cells (Dendritic) : Role of, in the Infective Colour Transformation of Guinea Pig's Skin (R. E. Billingham and Prof. P. B. Medawar), 61
Cellulose : Enzymatic Hydrolysis of, by *Coniophora cerebella* (Prof. F. F. Nord and J. C. Vitucci), 261
  Formation of, by *Acetobacter acetigenum* (R. Kaushal and Dr. T. K. Walker), 572
Cellulose (Cyanoethyl) : Crystal Structure of (Dr. F. Happey and Dr. J. H. MacGregor), 907
Cellulose Chemistry : The Methods of (Dr. Charles Dorée), second edition, *review* by Prof. E. L. Hirst, 450
Centenary of the Exhibition of 1851, 821
Central Library of the World : A, 562
Century of British Chemistry (Dr. F. Sherwood Taylor), 84
Cephalin Flocculation Curve (Serial) : A Non-Specific Resistance Factor in the Albumin Residue revealed by the (Dr. Jack G. Makari), 201
Cereal Rust Fungi : Over-summering and Over-wintering of the (Dr. P. D. Critopoulos), 507
Cerium Oxide : Variation in Density of (R. C. Vickery), 830
Cetyl Pyridinium Bromide on the Water Absorption and Swelling of Soil : Effect of (K. E. Clare), 828
Chain Molecules of Native Starch in the B-Modification : Configuration and Packing of (Dr. D. Kreger), 369
Chain Reaction : Controlled Fast Neutron, 426
Changes due to Electron Bombardment in the Electron Microscope Specimen (Prof. E. F. Burton, R. S. Sennett and S. G. Ellis), 565
Charge in Turbulent Flow in Alluvium : Effect of (Sir Claude Inglis), 60
Chemical Basis of Muscle Contraction, *review* by Dr. Kenneth Bailey, 550
Chemical Carcinogenesis (Prof. J. W. Cook), 375
Chemical Carcinogenesis : Physico-Chemical Aspects of (William Anderson), 892
Chemical Composition of the Stars ([illegible] Hoyle), 744
Chemical Constitution of Keratin (Dr. H. Lindley), 190

- Chemical Crystallography (C. W. Bunn), *review* by Dr. Dorothy Crowfoot, 173
- Chemical Developments and our Daily Life, 35
- Chemical Industries : Hydrogenation in the Fuel and (Major Kenneth Gordon), 360
- Chemical Industry : Agricultural Products and the (Dr. J. L. Simonsen), 373
- Chemical Kinetics of the Bacterial Cell (Prof. C. N. Hinshelwood), *review* by Dr. J. Monod, 105
- Chemical Personalities a Century Ago (Prof. J. Read), 245
- Chemical Progress (edited by Dr. F. Sherwood Taylor), 477
- Chemical Significance : Crystallographic Technique and its (Prof. E. G. Cox), 428
- Chemical Societies' Practice : Indexing Practice—Trends in German, American and British (R. Brightman), 615
- Chemical Substances (Pure) : International Collection of, 822
- Chemical and Medical Dictionary : English—Spanish (Morris Goldberg), *review*, 418
- Chemie : Röntgenographisch-analytische (Prof. Dr. E. Brandenberger), *review* by Dr. M. F. Perutz, 208
- 'Cheminée de Nancy' (A. F. Dufton), 325
- Chemist : The Life of a—Memoirs of Vladimir N. Ipatieff, edited by Xenia Joukoff Eudin, Helen Dwight Fisher and Harold H. Fisher, translated by Vladimir Haensel and Mrs. Ralph H. Lusher (Prof. D. M. Newitt), 43
- Chemistry : Advanced Organic, *review*, 106
  - Fuel and (Dr. D. T. A. Townend), 530
  - History of, 84
  - Lecture Experiments in (G. Fowles), third edition, *review* by A. C. C., 814
  - Organic (Prof. Paul Karrer), translated by A. J. Mee, third English edition, *review* by Dr. Neil Campbell, 484
  - Physical, for Colleges (Prof. E. B. Millard), sixth edition, *review* by Dr. J. A. V. Butler, 592
  - Physical, at Durham, 291
  - Physical, of Process Metallurgy (Faraday Society general discussion on), 564
  - Terpene, *review* by Prof. John Read, 384
  - Text-book Organic (A. T. Austin, Prof. E. D. Hughes and Prof. C. K. Ingold), 406 ; (Dr. Neil Campbell), 875
- Chemistry (Agricultural) : A Practical Course in (Frank Knowles and Dr. J. Elphin Watkin), second edition, *review*, 553
- Chemistry (Alkaloid) : An Assay in Correlation arising from (Sir Robert Robinson), 815
- Chemistry (Applied) : Thorpe's Dictionary of, fourth edition, Vol. 7, Iodazide—Metallagic Acid, *review* by B. A. Ellis, 624; Vol. 8, Methal-Oils, Essential, *review* by Sir Norman Haworth, 692
- Chemistry (British) : A Century of (Dr. F. Sherwood Taylor), 84
  - The Development of, *review* by Prof. John Read, 657
- Chemistry (Carbohydrate) : Advances in (edited by W. W. Pigman and M. L. Wolfrom), Vol. 2, *review* by Dr. E. G. V. Percival, 208
- Chemistry (Cellulose) : The Methods of (Dr. Charles Dorée), second edition, *review* by Prof. E. L. Hirst, 450
- Chemistry (Free Radical) : Quantitative Aspects of (Prof. H. W. Melville), 778
- Chemistry (Organic) : Modern, *review* by Dr. Neil Campbell, 484
  - A Text-Book of (Dr. Julius Schmidt and Dr. H. Gordon Rule), revised and edited by Dr. Neil Campbell, fifth edition, *review*, 106
  - Elsevier's Encyclopædia of (edited by E. Josephy and F. Radt), Vol. 14, Tetracyclic and Higher-Cyclic Compounds, Series 3, Carboisocyclic Condensed Compounds, *review*, 626
- Chemistry (Physical) : Fundamental Principles of (Prof. Carl F. Prutton and Prof. Samuel H. Maron), *review* by Dr. J. A. V. Butler, 592
  - The Work of the Royal Institution in, in Great Britain (Prof. E. K. Rideal), 245
  - Summer School in (University of Cambridge Department of Physical Chemistry), 292
- Chemistry (Pure and Applied) : Eleventh International Congress of, 14, 246

- Cleaned Pictures at the National Gallery (Dr. H. J. Plenderleith), 523
- Climatic Conditions on Autumn Calvings : Influence of (Richard Phillips and J. L. Davies), 429
- Climatic Fluctuations and Vegetation Growth in Northern Finland during 1890–1939 (Dr. I. Hustich), 478 ; (E. W. Jones), 479
- Coal Supplies : Geology and the Future of (British Association, Section C (Geology) discussion on), 593
- Coalfields : Geology in the Development of the (Dr. Murray Macgregor), 284
- Cobalt Deficiency in Sligo (Dr. E. J. Sheehy), 873
- Coco-Nuts : No Pearls in, 653
- Coconut Conference, 823
- Coefficients of Crystals : Third-Order Elastic (Prof. S. Bhagavantam and D. Suryanarayana), 750
- Coercivity (High) : Interpretation of, in Ferromagnetic Materials (Prof. E. C. Stoner and E. P. Wohlfarth), 650
- Cohen (Ernst Julius) Memorial Lecture of the Chemical Society (Prof. F. G. Donnan), 360
- Coiling of Wool Induced by certain Reagents (Martin R. Freney), 799
- Collagen in Solutions of Alkalis and Strong and Weak Organic Bases : Uptake of Water by (Dr. J. H. Bowes and R. H. Kenten), 827
- Colonial Development : British, 171
- Colonial Exhibitions : Research Studentships and Dominion and (Trinity College, Cambridge), 898
- Colonial Territories (British) : Forestry in, 764

Colonies : On Governing (Colonel W. R. Crocker), 172
  Science in the (Dr. J. L. Simonsen), 284
Colony Count Test for Assessing the Total Number of Viable Bacteria in Raw and Heated Milk : Limitations of the (C. S. Morris and M. A. Edwards), 434
Coloration : Protective, in Insects and its Interpretation (Prof. G. D. Hale Carpenter), 343
Colorimetry (Two-Standard) : An Improved Biuret Reaction of Proteins and the (Dr. A. Sols), 89
Colour of Iodine Solutions (Dr. F. Fairbrother), 87
Colour Phenomena in the Perception of Fine Detail (Dr. W. S. Stiles), 880
Colour Reaction for the D Vitamins : A New (V. Villar Palasi), 88
Colour Transformation of Guinea Pig's Skin : Role of Dendritic Cells in the Infective (R. E. Billingham and Prof. P. B. Medawar), 61
Colour Vision : International Conference on, 664
  A Possible Central Mechanism for (Prof. W. E. Le Gros Clark and L. Chacko), 123
Colour Vision Defects : Frequencies of Sex-Linked Red-Green (Dr. R. W. Pickford), 335
Colour-dress of Hermaphrodite Teleostean Fish : Influence of Hypophyseal Hormone and of Nervous Impulses on the (Dr. O. Peczenik and M. Zei), 788
Coloured Lights : Some Fatigue Effects on the Human Retina produced by using (Prof. H. Hartridge), 538
Colourless Carborundum : Preparation of (R. Iley and Prof. H. L. Riley), 468
Combination Tones (H. G. Yates and R. Catherall), 198
Combustion Systems : Use of a Palladium Tube Technique in the Study of the Role of Hydrogen in (J. R. Arthur and E. Sterling), 869
Combustion and Furnaces : Fuels, (Prof. John Griswold), *review* by H. J. Hodsman, 5
Comets and Meteoric Ionization : Meteors, (Physical Society discussion on), 76
Community : Physiology and the, 345
  The Police Court and the (Miss J. E. R. Kennedy), 803
Complex Variable : Functions of a (Prof. Thomas M. Macrobert), third edition, *review* by J. H. Pearce, 626
Composition and Structure of the Liver Cell in Pregnancy (Dr. H. W. Kosterlitz and Rosa M. Campbell), 676
Composts and Sewage Sludges : Estimation of Potassium in (P. Garrick), 434
Compounds : Antitubercular Activity of Diphenyl Ethers and related (Dr. Vincent C. Barry, L. O'Rourke and D. Twomey), 800
Compounds (Organic) : A New Notation and Enumeration System for (Dr. G. Malcolm Dyson), *review* by R. Brightman, 175
Compounds involving Copper Diphenylacetate : Molecular (Dr. Malcolm Crawford), 19
Computation of the Free Energy of *a*-Ketoglutarate and Pyruvate from Constants of the Transamination Process (S. Darling), 403
Concrete and Bituminous Materials : Soils, *review*, 518
Conduction of Heat in Solids (Prof. H. S. Carslaw and J. C. Jaeger), *review* by Prof. L. Rosenhead, 886
Conductivity of Evaporated Films of Lead Selenide (O. Simpson), 791
Configuration of Dialkyl Naphthenes : Geometrical (Dr. S. F. Birch and W. J. Oldham), 368
Configuration and Packing of Chain Molecules of Native Starch in the B-Modification (Dr. D. Kreger), 369
Coniophora cerebella : Enzymatic Hydrolysis of Cellulose by (Prof. F. F. Nord and J. C. Vitucci), 261
Conjugated Glucuronides : Formation of Glucuronic Acid during the Enzymic Hydrolysis of (Dr. G. A. Levvy), 54
Conjugated Polyolefins (Cyclic) : Synthesis of (D. H. S. Horn, J. R. Nunn and Dr. W. S. Rapson), 829
Conservation of Nature in England and Wales : Report of the Huxley Committee on, 809
Conservation of Nature in Scotland : National Parks and (Report of the Scottish National Parks Committee on), 809
Constants : Universal, in Blackett's Formula (H. Y. Tzu), 746
Constants (Dissociation) : Relationship between the, of Unsymmetrical Dicarboxylic Acids (Dr. D. H. R. Barton), 752
Constants of the Transamination Process : Computation of the Free Energy of *a*-Ketoglutarate and Pyruvate from (S. Darling), 403
Constituents (Major) : Contribution of the, to the Refractice Index of Milk (K. S. Rangappa), 719
Consumer Tastes : The Investigation of Trends of (L. R. England), 686
Contamination in Experimental Carcinogenesis : Risk of (Wm. Anderson), 338
Continental Butterflies : Immigration into Britain of, 359
Control of Atomic Energy, 655 ; (Dr. E. H. S. Burhop), 910
  International (Association of Scientific Workers discussion on), 426
  International, 460
Control of Metamorphosis in Insects : The Corpus Allatum and the (Dr. V. B. Wigglesworth), 16
Control of the Relapsing Fever Tick in African Houses : Economic (W. F. Jepson), 874
Controlled Fast Neutron Chain Reaction, 426
Converter (Electro-pneumatic) : Low-Pressure Amplifier and (Negretti and Zambra, Ltd.), 325
Coombe Rock (Baker's Hole) : Age of the, Northfleet, Kent (Prof. H. Breuil), 831
Co-operation in Botanical Research (Prof. C. W. Wardlaw), 804
Co-operation versus Isolation in Botanical Research (Dr. I. W. Bailey), 804
Co-operative Research in Industry (Dr. D. W. Hill), *review* by R. Brightman, 346
Co-ordinate Bond Formation by Olefins (L. Bateman), 56
Co-ordination Complexes containing Olefines (Prof. A. E. A. Werner), 644
Copley Medal for 1947 of the Royal Society awarded to Prof. G. H. Hardy, 704, 839
Copper : Activation of, by Oxidation and Reduction (F. C. Aldred and Dr. F. Happey), 267
  A Volatile Compound of (Dr. F. Körösy), 21 ; (J. G. Maltby), 468
Copper in Diatoms (Dr. H. Barnes and K. A. Pyefinch), 97
Copper Diphenylacetate : Molecular Compounds involving (Dr. Malcolm Crawford), 19
Coprecipitation of Uranous Sulphate with Rare-Earth Double Sulphates (Dr. A. W. Wylie), 830
Coptotermes curvignatus, Holmgr. : A Fungus Parasitic on (R. A. Altson), 120
Cordia macrostachya : Introduction of a Beetle from Trinidad into Mauritius to control *l'herbe Conde* (Dr. S. Maulik), 194
Core-Sampler : The Piston (Dr. B. Kullenberg), 410
Corpus Allatum and the Control of Metamorphosis in Insects (Dr. V. B. Wigglesworth), 16
Correlation arising from Alkaloid Chemistry : An Essay in (Sir Robert Robinson), 815
Correlation between Penicillin Resistance and Assimilation Affinity in *Staphylococcus aureus* (Dr. Ernest F. Gale), 407
Correlation Coefficient (Tetrachoric) : Nomogram for the (Max Hamilton), 473
Correlation Effects with Annihilation Radiation : Angular (Prof. M. H. L. Pryce and J. C. Ward), 435
Correlation Theory : A Pitfall in (Miss S. P. Vaswani), 405
Corticrocin, a Mycorrhiza Pigment (Prof. Holger Erdtman), 331
Cosmic Ray Showers : Observations Underground of Penetrating (Dr. E. P. George and A. C. Jason), 327
Cosmic Ray Stars at Sea-Level : Origin of (D. H. Perkins), 707
Cosmic Rays and Cancer (Dr. Frank H. J. Figge), 823
Cosmos (and the Second 'Law') : The Matter-Radiation Cycle in the—the Sun's Equilibrium (Alfred Lauck Parson), 906
Countryside : Footpaths and Access to the (Report of the Hobhouse Committee on), 809
Cow (Shorthorn) : A Tri-colour (Mosaic), (I. Chester Jones), 337
Crack Detection : Methods of (Institute of Physics, Industrial Radiology Group, symposium on), 556
Cracks in Glass Tubing : Spiral (I. C. P. Smith), 232
Creatine : Identification of, by Partition Chromatography (G. A. Maw), 261
Creative Arts : Science and the (W. B. Honey), *review* by F. Ian G. Rawlins, 418
Creep Law : Andrade's, and the Flow of Zinc Crystals (A. H. Cottrell and V. Aytekin), 328
Cricket Bat Willow : Cultivation of the, 807
Crioceris merdigera : Willow as Host-Plant of (Dr. S. Maulik), 609
Criterion to Determine the Group to which an Individual Belongs : A Statistical (C. Radhakrishna Rao), 835
Critical Moisture Content of Dehydrated Stockfish (G. F. van Wyk), 872
Crops (Glasshouse) : Pathology of, 915
Cross-Sections for Production of Artificial Mesons (Cécile Morette and Dr. W. H. Peng), 59
Crude Drugs and other Raw Materials of Vegetable and Animal Origin, *review* by Dr. W. O. Howarth, 4
Crystal Analysis : Polarized Infra-Red Radiation as an Aid to (D. A. Crooks), 17
Crystal Structure of *Para*-bromochloro-benzene (A. Klug), 570
Crystal Structure of Cyanoethyl Cellulose (Dr. F. Happey and Dr. J. H. MacGregor), 907
Crystal Structure of Human Carboxyhæmoglobin (Dr. M. F. Perutz and Olga Weisz), 786
Crystal Structure of Hydroxylammonium Chloride and Bromide (Miss Bodil Jerslev), 641
Crystal Structure Models (Crystal Structures, Ltd.), 325
Crystal Structures of *para*-Dinitrobenzene and *para*-Nitraniline (S. C. Abrahams and Prof. J. Monteath Robertson), 569
Crystal Structures of Zinc and Magnesium Benzene Sulphonates (J. M. Broomhead and A. D. I. Nicol), 795
Crystalline Bacterial Catalase (Dr. Denis Herbert and Audrey Jane Pinsent), 125
Crystalline Principle from *Ammi majus* L. (Prof. I. R. Fahmy, H. Abushady, Prof. A. Schönberg and Aly Sina), 478
Crystallographic Technique and its Chemical Significance (Prof. E. G. Cox), 428
Crystallography : Chemical (C. W. Bunn), *review* by Dr. Dorothy Crowfoot, 173
Crystals : Barium Titanate (H. F. Kay and R. G. Rhodes), 126
  Second-Order Raman Spectra of (Dr. R. S. Krishnan), 230
  Temperature Variation of the Second-Order Raman Spectrum of (Prof. E. Gross and A. Stehanov), 568
  Third-Order Elastic Coefficients of (Prof. S. Bhagavantam and D. Suryanarayana), 750
Crystals' ('Stimulated) : Growth of, and Rate of Nucleation during Re-crystallization of Aluminium (Prof. W. G. Burgers), 398
Crystals of Barium Titanate : Dielectric Properties of Single (J. K. Hulm), 127
Cult of the Superman : The (Eric Bentley), *review* by A. D. R., 592
Cultural Phenomena : A Study of, 743
Culture : Sociological Significance of Language and, 205
Curare and the Potassium Ion : Antagonism between (J. P. Quilliam and Dr. D. B. Taylor), 602
Curie Point of Barium Titanate (M. G. Harwood, P. Popper and D. F. Rushman), 58
'Curling-Factor' : Identity of Griseofulvin and (J. F. Grove and Dr. J. C. McGowan), 574
Currents causing the Solar and Lunar Diurnal Magnetic Variations : Location of the (Dr. D. F. Martyn), 535
Cushion Cells in Retinal Pre-capillaries and Capillaries (Prof. Arnold Loewenstein), 229
Customs of Newfoundland-Labrador (the Eastern Part of the Labrador Peninsula) : Outlines of the Geography, Life and (Prof. V. Tanner), *review*, 735
Cutaneous Pain 'Spots' : Significance of Multiple Innervation of, in relation to the Quality of Pain Sensibility (Dr. G. Weddell, D. C. Sinclair and W. H. Feindel), 27
Cyanoethyl Cellulose : Crystal Structure of (Dr. F. Happey and Dr. J. H. MacGregor), 907
Cyclic Conjugated Polyolefins : Synthesis of (D. H. S. Horn, J. R. Nunn and Dr. W. S. Rapson), 829
Cyclo-octatetraene : Structure and Diamagnetic Susceptibility of (R. C. Pink and Prof. A. R. Ubbelohde), 502
Cyclo-octatetraene (C_8H_8) : The 'Octa-Benzene', (O. Bastiansen, Prof. O. Hassel and Prof. A. Langseth), 128

Cyclopropane : Formulæ for Ethylene Oxide and (Sir Robert Robinson), 162
    Structure of (Dr. H. A. Skinner), 902 ; (Dr. A. D. Walsh), 902
    Structure of Ethylene Oxide and (Dr. J. W. Linnett), 162
Cyclopropane and Ethylene Oxide : Structure of (T. M. Sugden), 367
Cyprinodon dispar Rueppel : A New Locality for (Dr. H. Mendelsohn), 123
Cytology (Experimental) : Sixth International Congress of, 443
Cytology of Alimentary Tract and Associated Glands of the Fowl, *Gallus domesticus* (Dr. K. S. Chodnik), 62

DAILY Life : Chemical Developments and our, 35
Dalton Lecture of the Manchester and District Section of the Royal Institute of Chemistry (Dr. D. T. A. Townend), 530
Dams (Large), International Congress on : To be held in Sweden in 1948, 784
Danish Marine Bottom Invertebrates : Reproduction and Larval Development of (Dr. Gunnar Thorson), 766
Danish Species of *Alternaria* and *Stemphylium* (Paul Neergaard), *review* by Dr. S. P. Wiltshire, 313
Daphnia Hæmoglobin (Prof. H. Munro Fox), 431
Darwin (George) Lecture of the Royal Astronomical Society (Prof. J. H. Oort), 203
Darwin's Finches (David Lack), *review* by Dr. W. S. Bullough, 853
Davidson (Mackenzie) Memorial Lecture of the British Institute of Radiology (Dr. John H. Lawrence), 51
Davy Medal for 1947 of the Royal Society awarded to Prof. Linus C. Pauling, 704, 840
Day : Influence of Variation in Length of, upon the Breeding Season in Sheep (N. T. M. Yeates), 429
'DD' as a means of Controlling *Heterodera rostochiensis* (Woll.), (George C. Martin), 720
D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in South Africa (Dr. P. J. du Toit), 485
D.D.T. on Mud : Insecticidal Effect of Surface Deposits of (A. B. Hadaway and F. Barlow), 363
Decay of Luminescence due to Forbidden Optical Transitions (G. F. J. Garlick and A. F. Gibson), 303
Decay of Negative Mesons in Matter (Dr. H. Fröhlich), 255
Decomposition of Organic Nitrates : Thermal (L. Phillips), 753
Deep-Sea Expedition : The Swedish (Prof. Hans Pettersson), 559
Definition of Nuclear Quadrupole Moments (E. H. Rhoderick), 255
Deformed Metals (Plastically) : Residual Lattice Strains in (G. B. Greenough), 258
Degradation of Large Molecules : Mechanical (William John Morris and Dr. Robert Schnurmann), 674
Dehydrated Stockfish : Critical Moisture Content of (G. F. van Wyk), 872
Delinquency (Juvenile) : Biology and (Dr. E. R. Frey), 803
Demonstration Models of Physical Processes (Dr. F. A. Ward), 151
Dendritic Cells in the Infective Colour Transformation of Guinea Pig's Skin : Role of (R. E. Billingham and Prof. P. B. Medawar), 61
Density of Cerium Oxide : Variation of (R. C. Vickery), 830
Dermatologie : Précis de (J. Darier, A. Civatte et A. Tzanck), cinquième édition par A. Civatte, *review* by Dr. James Marshall, 592
Desert Locust (*Schistocera gregaria*) in Eastern Africa : Seasonal Breeding and Migrations of the (Z. Waloff), 67
Design of Experiments (Prof. Ronald A. Fisher), fourth edition, *review* by K. M., 774
Detail (Fine) : The Visual Perception of (Prof. H. Hartridge), 880
Detection of the Free Amino-Acids of Plant Cells by Partition Chromatography (Dr. C. E. Dent, W. Stepka and Prof. F. C. Steward), 682
Detection by Radar of a New Meteor Shower, 118
Detergency : Surface Tension and (Dr. C. C. Addison), 467
Detonating Explosives : Mach Waves in Shock Wave Systems from (D. W. Woodhead and R. Wilson), 672
Detonation in High Explosives : Spread of (Dugald Mitchell and Stewart Paterson, 438
Detonation of a Tubular Charge of Explosive : Velocity of (D. W. Woodhead), 644
Detonation Wave in High Explosives : Speed Around the Initiating Point of the (W. C. F. Shepherd), 92
Deuteron : Nuclear Forces and the Magnetic Moment of the (Prof. H. S. W. Massey and Tsi-Ming Hu), 794
    Photo-Disintegration of the (W. M. Gibson, L. L. Green and D. L. Livesey), 534
Development of Accessory Glands and Spermatogenesis : Functional (Dr. D. V. Davies and Dr. T. Mann), 295
Development in Great Britain : Government Research and, 379
Development Plan for Uganda (Dr. E. B. Worthington), 172 ; *review* by Prof. Walter Fitzgerald, 691
Diagnosis of Hæmolytic Disease in the Newborn : Determination of Bilirubin in the Umbilical Blood as as Aid in the Early (Dr. A. Sadowski, Y. M. Bromberg and A. Brzeziński), 192
Dialkyl Naphthenes : Geometrical Configuration of (Dr. S. F. Birch and W. J. Oldham), 368
Dialysate ? : What is a (Dr. N. W. Pirie), 198 ; (Dr. H. G. Derx), 720
Diamagnetic Susceptibility of Cyclo-octatetraene : Structure and (R. C. Pink and Prof. A. R. Ubbelohde), 502
Diamond : Inequality of (III) X-Ray Reflections in (Dr. W. A. Wooster and G. L. Macdonald), 500
Diaphragm (Rat) : Effect of Injection of Adrenaline on the Anærobic Glycolysis of (Dr. J. A. Cohen), 871
Diatoms : Copper in (Dr. H. Barnes and K. A. Pyefinch), 97
Dibenzoylphosphate : Hippuric Acid Formation from Glycine and (H. Chantrenne), 603
Dicarboxylic Acids (Unsymmetrical) : Relationship between the Dissociation Constants of (Dr. D. H. R. Barton), 752
Dicotyledonous Woods : Initial Parenchyma Cells in (K. A. Chowdhury), 609
Dictionary : English—Spanish Chemical and Medical (Morris Goldberg), *review*, 418
Dictionary of Applied Chemistry : Thorpe's, fourth edition, Vol. 7, Iodazide—Metallagic Acid, *review* by B. A. Ellis, 624; Vol. 8, Methal-Oil, Essential, *review* by Sir Norman Haworth, 692
Dictyostele in *Dryopteris aristata* : Experimental Production of a Protostele from a (Prof. C. W. Wardlaw), 539
Dielectric Losses and Fluorescence of Zinc Silicate (G. Szigeti and E. Nagy) 641
Dielectric Properties of Single Crystals of Barium Titanate (J. K. Hulm), 127
Dielectric Residual Effects in Titanates (Prof. J. R. Partington, G. V. Planer and I. I. Boswell), 877
Diet and Vitamins, *review* by Dr. Leslie J. Harris, 242
4 : 4-Diethoxydinaphthyl : A Semi-Quinonoid Oxidation Product of (G. Baddeley, P. Graddon and Prof. J. Kenner), 185
Differential Equations (Second-Order) : Eigenfunction Expansions associated with (Prof. E. C. Titchmarsh), *review*, 174
Diffraction of X-Rays by the Alloy $AuCu_3$ (I. G. Edmunds, R. M. Hinde and Dr. H. Lipson), 304 ; (Prof. A. J. C. Wilson), 304
Diffraction and Optical Image Formation (Prof. F. Zernicke), 394
Diffusion of Dissolved Substances through Thalli and Leaves of Aquatic Plants (Prof. E. Steemann Nielsen), 376
Diisopropylfluorophosphonate : Central Excitant Action of (Mary Chennells and Prof. Samson Wright), 503
Dilute Aqueous Solutions of Acrylonitrile : Effect of Gamma- and X-Rays on (Dr. F. S. Dainton), 268
Dilute Suspension : Maintenance of Spermatozoal Motility in (Dr. C. W. Emmens and G. I. M. Swyer), 718
Dimensions of Personality (Dr. H. J. Eysenck), *review* by Dr. Clifford Allen, 887
Dimerization Reactions in Sunlight (Prof. Alexander Schönberg, Ahmed Mustafa and Mohamed Zaki Barakat), 401
Dimethylnitramine : Structure of (Dr. W. Costain and Prof. E. G. Cox), 826
Dinosaurs : The (Dr. W. Norman Maple), 343
Diodora gibberula (Lam.) : Sex Reversal in *Patella coerula* L. and (G. Bacci), 94
Diphenyl Ethers and related Compounds : Antitubercular Activity of (Dr. Vincent C. Barry, L. O'Rourke and D. Twomey), 800
Dipole Moments and Structure of the Sydnones (Prof. Wilson Baker, W. D. Ollis, V. D. Poole, J. A. Barltrop, R. A. W. Hill and L. E. Sutton), 366
Diptera : White-eyed Mutants of (Prof. A. H. Sturtevant), 754
Direct-Current Conductance of Keratin and Nylon : Effect of Polar Vapours on the (G. King and J. A. Medley), 438
Discovery of Chloroform Anæsthesia, 668
Diseases of Flax (Dr. R. McKay), 254
Diseases of the Lower Animals : Relation of, to Human Welfare (New York Academy of Sciences, Section of Biology, conference on), 237
Disintegration (Photo-) of the Dueteron (W. M. Gibson, L. L. Green and D. L. Livesey), 534
Displacement Chromatography on Cation-Exchange Materials (J. R. Bendall, S. M. Partridge and R. G. Westall), 374
Displacements in Stress-Strain Problems : Large Strains and (Dr. K. H. Swainger), 399
Dissection of the Cat, *review* by Dr. N. B. Eales, 210
Dissociation Constants of Unsymmetrical Dicarboxylic Acids : Relationship between the (Dr. D. H. R. Barton), 752
Dissolved Substances : Diffusion of, through Thalli and Leaves of Aquatic Plants (Prof. E. Steemann Nielsen), 376
Distribution Curves (Trichromatic) : Transformation of (A. Marriage), 197
Ditchling Common : The Ecology of (P. J. Wanstall), 343
Divers (British) : Haunts of (Niall Rankin), *review* by Dr. E. Hindle, 693
Dolphins : Sound Emitted by (B. Kullenberg), 648 ; (Dr. F. C. Fraser), 759
Domestic Fowl : Gonadal Hormones and Mineral Balance in the (Dr. R. H. Common, W. A. Rutledge and R. W. Hale), 541
Dominance and Recessiveness in the Human Blood Groups (Dr. A. E. Mourant), 353
Dominion and Colonial Exhibitions : Research Studentships and (Trinity College, Cambridge), 898
Drug : Miracle—the Inner History of Penicillin (David Masters), *review* by Prof. L. P. Garrod, 38
Drugs : Crude, and other Raw Materials of Vegetable and Animal Origin, *review* by Dr. W. O. Howarth, 4
Drying and Purification of Humus and Allied Materials : Freezing as an Aid in the (Dr. W. G. C. Forsyth and G. K. Fraser), 607
Dryopteris aristata : Experimental Production of a Protostele from a Dictyostele in (Prof. C. W. Wardlaw), 539
Duddell Medal for 1947 of the Physical Society awarded to Dr. R. J. Van de Graaff, 495
Dutch Pioneers in Science and Industry, *review* by Lieut.-Colonel Ernest Tillotson, 449
Dyeing : Theory and Practice of (Society of Dyers and Colourists symposium on), 16, 698
Dyestuffs : British, 528

EAR (Human) : Transient Reception and the Degree of Resonance of the (Dr. R. J. Pumphrey and T. Gold), 124
Earth, Stars and Radio (Sir Edward Appleton), 283
Earth's Atmosphere : The Radiations from the (Prof. S. Chapman and D. R. Bates), 250
Earth's Magnetic Field : Blackett's Fundamental Theory of the (A. L. Hales and D. I. Gough), 746
Earthquakes registered in Switzerland during 1945, 636
East African Lakes : Speciation in Cichlid Fishes of (Dr. Ethelwynn Trewavas), 96
East-West Rooms : Radiant Temperatures of Walls in North-South and (J. Neumann), 472
Eastern Africa : Seasonal Breeding and Migrations of the Desert Locust (*Schistocera gregaria*) in (Z. Waloff), 67
Eclipse of May 20 : Total Solar (Preliminary Reports of the), 49
Ecology of Ditchling Common (P. J. Wanstall), 343
Ecology of Norway, *review* by Prof. I. Manton, 4
Economic Aspects of National Health : Present-Day Social and (American Philosophical Society symposium on), 360
Economic Consequences of Science : Some (Dr. Sumner H. Slichter), 622
Economic Control of the Relapsing Fever Tick in African Houses (W. F. Jepson), 874

Economy (National) : Patents and the, *review* by Sir William Jarratt, 482
Education : Biology in (British Social Hygiene Council conference on), 785
  Social Improvement by, *review*, 625
  Mass, and International Understanding, 689
  Vocational, in the United States, 326
Education (Adult) : Visual Aids in—Royal Army Educational Corps Exhibition (Colonel J. T. Burgess), 411
Education (Post-Primary) : Science in (Association of Women Science Teachers Report, Part 3), 783
Education (Secondary) : The Evolution of, in Britain (Lynda Grier), 289
Education (Technical) : International Congress at the Technische Hochschule, Darmstadt (James T. Kendall), 721
  Science and, in Germany, 721
Education in H.M. Forces, 528
Education of the Man of Science (Sir John Lennard-Jones), 520
Education for Management (Report of a Special Committee of the Ministry of Education), 69
Education in the Royal Air Force, 253
Education Courses : Army—Preparation for Marriage (R. Weatherall), 684
Education Service in Germany : British Families (F. J. Downs), 147
Education and Training of Laboratory Technicians, 635
Efficiency in the Civil Service : Recruitment and, 239
Eggs of the Sea Urchin, *Psammechinus miliaris* : Respiration and Cell-Division in (Dr. Erik Zeuthen), 577
Eigenfunction Expansions associated with Second-Order Differential Equations (Prof. E. C. Titchmarsh), *review*, 174
Elastic Coefficients of Crystals : Third-Order (Prof. S. Bhagavantam and D. Suryanarayana), 750
Electric Contacts (Dr. Ragnar Holm), *review* by Prof. F. Llewellyn Jones, 417
Electric Heater for Flasks, 862
Electric Potentials : Structures Produced in Clays by, and their relation to Natural Structures (Leo Casagrande), 470
Electrical Engineering in the University of Alberta, 83
Electrical Engineers (Professional) : The Practical Training of (Institution of Electrical Engineers), 585
Electrical Fluctuations in Thermionic Valves : A Unified Theory of Spontaneous (Dr. R. Fürth), 832
Electrical Transmissions in Steady State (Paul J. Selgin), *review* by Dr. R. L. Smith-Rose, 206
Electrical and Light Units : Introduction of New (Sir Charles Darwin), 167
Electrochemical Theories of the Course of Reactions of Carbon Compounds (Sir Robert Robinson), 245
Electro-pneumatic Converter : Low-Pressure Amplifier and (Negretti and Zambra, Ltd.), 325
Electrode Processes (Faraday Society discussion on), 306
Electrolytes (Molten) : Anode Phenomena in (A. J. Rudge, W. N. Howell and H. Hill), 504
Electron : Jubilee of the Discovery of the, 358, 704
Electron Affinity of ClO (Dr. H. A. Skinner), 716 ; (Dr. Joseph Weiss), 717
Electron Bombardment in the Electron Microscope : Specimen Changes due to (Prof. E. F. Burton, R. S. Sennett and S. G. Ellis), 565
Electron Density in Meteor Trails (Dr. A. C. B. Lovell), 670
Electron Jubilee Exhibition (Science Museum), 460
  Handbook to the Electron Jubilee Exhibition (D. H. Follett), 460
Electron Liberated : The (Sir Clifford Paterson), 358, 776
Electron Microscope : Specimen Changes due to Electron Bombardment in the (Prof. E. F. Burton, R. S. Sennett and S. G. Ellis), 565
Electron Microscope Investigation of the Action of Salt Solutions on Myosin (Prof. Silvio Ranzi), 712
Electron Microscope Studies of Normal and Malignant Tissues of High- and Low-Breast-Cancer Strains of Mice (Prof. R. D. Passey, Dr. L. Dmochowski, Prof. W. T. Astbury and Dr. R. Reed), 565
Electron Microscopy : Progress in (Electron Microscopy Group of the Institute of Physics conference on), 762
Electron Microscopy of Bacteria (E. M. Brieger, G. R. Crowe and Dr. V. E. Cosslett), 864
Electronic Equipment at the Royal Aircraft Establishment, 444
Electronic Motion : Valve with Trochoidal (Prof. H. Alfvén and H. Romanus), 614
Electronic Servo Simulators (Prof. F. C. Williams), 340
Electronic Waves ? : Spherical (W. E. Benham), 160
Electrons : Excitation of Nuclei by (Dr. Bruno Touschek), 500
  Travelling-Wave Linear Accelerator for (D. W. Fry, R. B. R.-S. Harvie, L. B. Mullett and W. Walkinshaw), 351
Electrons and their Utilization (Institution of Electronics exhibition of), 652
Electrons and Positrons produced by a 20-MeV. Betatron : Some Experiments with Fast (W. Bosley, Dr. J. D. Craggs and W. F. Nash), 790
Electrophoresis (Preparative) : An Apparatus for (Dr. J. A. V. Butler and Miss J. M. L. Stephen), 469
Element 23 : The Name of (Prof. Manuel Sandoval Vallarta and Arturo Arnaiz y Freg), 163 ; (Prof. F. A. Paneth), 164
Elements : Naming the—a Former Suggested Use of 'Plutonium' (Dr. K. R. Webb), 164
Elliot (Daniel Giraud) Medal for 1945 of the U.S. National Academy of Sciences awarded to Dr. Sewall Wright, 169
Embryology : Experimental, in the Netherlands, 1940–1945 (Prof. M. W. Woerdeman and Prof. Chr. P. Raven), *review*, 626
Embryology of *Temnocephala novaezealandiae* Haswell (Roy A. Harrison), 798
Embryonic Chicken Brain : Cultivation of the Erythrocytic Form of *Plasmodium gallinaceum* in Tissue Cultures of (Herta Meyer), 155
Emission Spectra of the Night Sky and Aurarae (Royal Society, Gassiot Sub-Committee B, conference on), 16
Emission Spectrum of Iodine Molecules in the Presence of an Inert Gas (Jürg Waser and Dr. K. Wieland), 643
Empire : Universities of the (Congress of the), 51
Empire Scientific Conference, Royal Society : Preliminary Report of the, 185
Employment in Scotland : Industry and (Scottish Office report on), 341
Encephalomyelitis Virus : Chick Embryos Surviving the Inoculation of an Equine Strain of (Dr. José J. Monteverde and Dr. Domingo H. Simeone), 680
Encyclopædia of Human Genetics, *review* by Prof. F. A. E. Crew, 274
Encyclopædia of Organic Chemistry : Elsevier's (edited by E. Josephy and F. Radt, Vol. 14, Tetracyclic and Higher-Cyclic Compounds, Series 3, Carboisocyclic Condensed Compounds, *review*, 626
Endostyle of Ammocoetes : Effect of Thiourea on the (Miss R. P. Jones), 638
Energy (High-Frequency) : Production of, by Ionized Gases (J.-L. Steinberg), 833
Energy of Activation of the Transamination between Glutamic Acid and Pyruvic Acid : Optimum *p*H and Temperature, and (S. Darling), 838
Energy of *α*-Ketoglutarate and Pyruvate : Computation of the Free, from Constants of the Transamination Process (S. Darling), 403
Energy Sources for the 'Second Meson' Events : Hypothetical Alternative (Dr. F. C. Frank), 525
Engineer : Relaxation Methods, a Method for the (Dr. R. V. Southwell), 462
Engineering (Civil) : Soil in (A. H. Toms), 343
Engineering (Modern) : Progress in (Sir William Halcrow), 286
Engineering Degree Courses for Ex-Servicemen (O. S. Puckle), 50, 325
Engineering Vibration Problems : The Escalator Method in (Joseph Morris) *review* by Prof. W. J. Duncan, 623
Engineers : Mathematical Aids for (Raymond W. Dull), *review*, 349
Engineers and Physicists : Applied Mathematics for (Dr. Louis A. Pipes). *review* by E. N. Fox, 552
England : Occurrence of *Botrytis Fabae* Sardiña in (L. Ogilvie and M. Munro), 96
  Peach Orchards in (Justin Brooke), *review*, 814
  Sclerotinia Porri on *Allium* spp. in (James F. H. Cronshey), 798
England (South-East) : Some Archæological Problems in (Dr. A. E. Wilson), 343
England (Southern) : Bird Haunts in (G. K. Yeates), *review* by Frances Pitt, 314
England and Wales : Conservation of Nature in (Report of the Huxley Committee on), 809
  National Parks in (Report of the Hobhouse Committee on), 809
English—Spanish Chemical and Medical Dictionary (Morris Goldberg), *review*, 418
Ensheathed Rotating Knife for Causing Brain Lesions : An (Dr. P. Glees, P. D. Wall and T. A. Wright), 365
Entropy Fluctuations in Liquid Helium II and the Rayleigh Line (B. K. Agarwala and A. G. Chowdri), 750
Enumeration System for Organic Compounds : A New Notation and (Dr. G. Malcolm Dyson), *review* by R. Brightman, 175
Enzymatic Hydrolysis of Cellulose by *Coniophora cerebella* (Prof. F. F. Nord and J. C. Vitucci), 261
Enzymatic Syntheses : Aspects of the Biological Function of Phosphate in (Dr. Herman M. Kalckar), 143
Enzyme Action : Mucin as Substrate of, by Viruses of the Mumps Influenza Group (Dr. F. M. Burnet, J. F. McCrea and S. G. Anderson), 404
Enzyme Specificity in the Domain of Carbohydrates ; Mechanism of (Dr. A. Gottschalk), 113
Enzyme Studies on the Mechanism of Wood Decay (Prof. J. J. Nord and J. C. Vitucci), 224
Enzymic Hydrolysis of Conjugated Glucuronides : Formation of Glucuronic Acid during the (Dr. G. A. Levvy), 54
Epithelial Tissue in *Rhodnius prolixus* (Hemiptera) : A Method for Observing Growing (Dr. M. Lüscher), 873
Epizoites : Urceolarian, of Flatworms (Dr. T. B. Reynoldson), 265
Equations (Second-Order Differential) : Eigenfunction Expansions associated with (Prof. E. C. Titchmarsh), *review*, 174
Equine Strain of Encephalomyelitis Virus : Chick Embryos Surviving the Inoculation of an (Dr. José J. Monteverde and Dr. Domingo H. Simeone), 680
Errors (Probable) : Over-estimation of (R. T. Leslie), 751
Erythrean Fishes on the Mediterranean Coast of Palestine (Dr. G. Haas and G. Steinitz), 28
Erythrocytic Form of *Plasmodium gallinaceum* in Tissue Cultures of Embryonic Chicken Brain : Cultivation of the (Herta Meyer), 155
Escalator Method in Engineering Vibration Problems (Joseph Morris), *review* by Prof. W. J. Duncan, 623
Escape of Thoron from Thorium X Salts (Dr. F. Behounek and J. Klumpar), 640
Escherichia coli and the Production of Penicillinase : Biochemistry of (Dr. Luigi Gorini and Annamaria Torriani), 332, *errata*, 394
Essential Oil from a Fern (*Paesia scaberula*) : A Terpene-type (Dr. Lindsay H. Briggs and Maurice D. Sutherland), 333
Estimation in Inverse Sampling : Errors of (D. J. Finney), 195
Estimation of Mixtures of Sugars by the Paper Chromatogram Method : Quantitative (A. E. Flood, Prof. E. L. Hirst and Dr. J. K. N. Jones), 86
Ethanolamine on the Rate of Formation of Phospholipids of the Liver : Influence of Choline and (Dr. A. P. Platt and R. R. Porter), 905
Ethics and Science : Conference on, 706
3-Ethyl-5 : 5-dimethyloxazolidine-2 : 4-dione : Preparation and Properties of (W. H. Hook), 610
Ethylene Oxide : Structure of Cyclopropane and (T. M. Sugden), 367
Ethylene Oxide and Cyclopropane : Formulæ for (Sir Robert Robinson), 162
  Structure of (Dr. J. W. Linnett), 162
Etiology of Strawberry Virus Diseases (Dr. Conway A. Wood and Dr. T. Whitehead), 761
European Raspberry Viruses : Aphid Vectors of (C. H. Cadman and A. R. Hill), 837
Evaporated Films of Lead Selenide : Conductivity of (O. Simpson), 791
Evaporation of Heavy Nuclei (D. H. Perkins), 299
Evaporation of Meteors (T. L. Eckersley), 91
Everyman : Palæobotany for, *review* by Prof. John Walton, 734
Evidence against Spontaneous Emission of Neutrons by Uranium X (Dr. Hl. de Vries and H. Groendijk), 435
Evolution on Galapagos, *review* by Dr. W. S. Bullough, 853
Evolution of Secondary Education in Britain (Lynda Grier), 289
Ex-Servicemen : Engineering Degree Courses for (O. S. Puckle), 50, 325
Examinations in Secondary Schools (Secondary School Examinations Council report on), 497
Exchange of Radio-Sodium in Isolated Muscle : Interpretation of the (Dr. Hans H. Ussing), 262

Excitant Action of Diisopropylfluorophosphonate : Central (Mary Chennells and Prof. Samson Wright), 503
Excitation of Nuclei by Electrons (Dr. Bruno Touschek), 500
Exhibitions : Research Studentships and Dominion and Colonial (Trinity College, Cambridge), 898
Expansion of the Scope of Science (Dr. Leslie A. White), 743
Expansions in Eigenfunctions, *review*, 174
Expenditure (Public) : Scientific Research and, 849
Experimental Carcinogenesis : Risk of Contamination in (Wm. Anderson), 338
Experimental Cytology : Sixth International Congress of, 443
Experimental Embryology in the Netherlands, 1940–1945 (Prof. M. W. Woerdeman and Prof. Chr. P. Raven), *review*, 626
Experiments : The Design of (Prof. Ronald A. Fisher), fourth edition, *review* by K. M., 775
Explosive : Velocity of Detonation of a Tubular Charge of (D. W. Woodhead), 644
Explosives (Detonating) : Nach Waves in Shock Wave Systems from (D. W. Woodhead and R. Wilson), 672
Explosives (High) : Speed Around the Initiating Point of the Detonation Wave in (W. C. F. Shepherd), 92
  Spread of Detonation in (Dugald Mitchell and Stewart Paterson), 438
Explosives (Liquid) : Properties of (R. G. Vines), 400

F_2 Ionization and Geomagnetic Latitudes (P. H. Liang), 642 ; (Sir Edward Appleton), 643
Fabrics : The Fireproofing of (J. E. Ramsbottom), *review* by Dr. C. S. Whewell), 278
Factory Power Exhibition : Home and (Science Museum), 600
Factual Film : The (Report of the Arts Enquiry), 513
Falkland Islands Dependencies Survey, 897
Family and on Population : International Congress on the, 183
Family Unit : The Public Health Nurse and the (Miss M. M. West), 803
Faraday Lecture (Sir Robert Robinson), 245
Farm : Folklore on the, *review* by Prof. John Read, 140
Farmer's Friend : The, or Wise Saws and Modern Instances (compiled and commented upon by W. S. Mansfield), *review* by Prof. John Read, 140
Fast Neutron Chain Reaction : Controlled, 426
'Fatigue' : Fluorescence (Dr. A. J. Henry), 163
Fatigue Effects on the Human Retina produced by using Coloured Lights : Some (Prof. H. Hartridge), 538
Faunas : Mesozoic, of Peru, 118
Feeding Mechanism of Water-bugs (Muriel Sutton), 122
Feeding Mechanisms of *Chironomus* Larvæ (Barbara M. Walshe), 474
Fellowship (Shirley) of the British Cotton Industry Research Association awarded to B. J. Mason, 428
Fellowship : Research, for work on the Structure of the Human Foot (University College London and the British Boot, Shoe and Allied Trades Research Association), 497
Fellowships : Commonwealth Fund, 744
  Leverhulme Research (Awards for 1947), 119
Fellowships for Medical Research : Beit Memorial, 152
Fellowships in the Natural Sciences (United States National Research Council), 824
Fern (*Paesia scaberula*) : A Terpene-type Essential Oil from a (Dr. Lindsay H. Briggs and Maurice D. Sutherland), 333
Fern Phyllotaxis : Tensile Stress as a Factor in (Prof. C. W. Wardlaw), 678
Ferrites : Gyromagnetic Resonance in (Dr. J. L. Snoek), 90
Ferromagnetic Dispersion : Mechanism of (J. B. Birks), 535
Ferromagnetic Materials : High-Frequency Permeability of (G. Eichholz and G. F. Hodsman), 302
  Interpretation of High Coercivity in (Prof. E. C. Stoner and E. P. Wohlfarth), 650
Fibres in Sheep : Replacement of (L. Auber and Marca Burns), 836
Fibrinokinase-Fibrinolysis System : Properties of the (Per M. Permin), 571
Field Size : Dependence of Anomaloscope Matching on Viewing Distance or (R. G. Horner and E. T. Purslow), 23 ; (Dr. J. H. Shaxby), 24 ; (Prof. H. Hartridge), 831
Film : The Factual (Report of the Arts Enquiry), 513
Film-Strip of the Principles of Bridges (Strip Slides), 393
Films of Lead Selenide (Evaporated) : Conductivity of (O. Simpson), 791
Filter Paper Chromatogram : Micro-Estimation of Sugars separated on the (J. R. Hawthorne), 714
Filter Paper Partition Chromatography to Radioactive Tracer Studies : Application of (Dr. R. M. Fink, Dr. C. E. Dent and K. Fink), 801
Filter Paper Pellets in the Spectrochemical Analysis of Solutions : Use of (Prof. N. S. Bayliss and D. J. David), 334
Finches : Darwin's (David Lack), *review* by Dr. W. S. Bullough, 853
Fine Detail : The Visual Perception of (Prof. H. Hartridge), 880
Finland (Northern) : Climatic Fluctuations and Vegetation Growth in, during 1890–1939 (Dr. I. Hustich), 478 ; (E. W. Jones), 479
Fire Risks in Ships : Reduction of (Dr. L. A. Jordan), 216
Fireproofing of Fabrics (J. E. Ramsbottom), *review* by Dr. C. S. Whewell, 278
Fish (Hermaphrodite Teleostean) : Influence of Hypophyseal Hormone and of Nervous Impulses on the Colour-dress of (Dr. O. Peczenik and M. Zei), 788
Fischer-Tropsch Synthesis : X-Ray Diffraction Studies of a Nickel-Thoria-Kieselguhr Catalyst for (Dr. K. M. Chakravarty and Ranjit Sen), 907
Fishes : 'Mimicry' in (Dr. Ethelwynn Trewavas), 120, 509 ; (Prof. G. D. Hale Carpenter), 508
  Erythrean, on the Mediterranean Coast of Palestine (Dr. G. Haas and H. Steinitz), 28
Fishes (Cichlid) : Speciation in, of East African Lakes (Dr. Ethelwynn Trewavas), 96
Flame Bands : Silicon (A. R. Downie and R. F. Barrow), 198
Flame Gases : Unusual (Prof. W. T. David and J. Mann), 229
Flasks : Electric Heater for, 862
Flatworms : Urceolarian Epizoites of (Dr. T. B. Reynoldson), 265
Flax Diseases (Dr. R. McKay), 254
Floating Magnet : A (Prof. V. Arkadiev), 330
'Floating Thread', a Surface Phenomenon on Flowing Water (I. Kuščer), 673
Flocculation Curve (Serial Cephalin) : A Non-Specific Resistance Factor in the Albumin Residue revealed by the (Dr. Jack G. Makari), 201
Flood : Built Before the (H. S. Bellamy), revised edition, *review* by G. H. S. Bushnell, 852
Flow in Alluvium : Turbulent (Gerald Lacey), 61
  Effect of Charge in Turbulent (Sir Claude Inglis), 60
Flow of Smoke through a Hole in a Resonant Cavity (F. W. Simpson), 93 ; Dr. Robert W. Lawson), 440
Flow of Zinc Crystals : Andrade's Creep Law and the (A. H. Cottrell and V. Aytekin), 328
Flower Development in Barley Involving Sex Reversal : Abnormal (Prof. F. G. Gregory and O. N. Purvis), 221
Flowering Responses in a Strain of *Orobanche minor* (M. Holdsworth and P. S. Nutman), 223
Flowing Water : The 'Floating Thread', a Surface Phenomenon on (I. Kuščer), 673
Fluids (Non-Newtonian) : Hydrodynamics of (R. S. Rivlin), 611
Flourescence of Cancerous and Non-Cancerous Lipoids (H. S. Penn and Prof. Joseph Kaplan), 18
Flourescence of Zinc Silicate : Dielectric Losses and (G. Szigeti and E. Nagy), 641
Flourescence et Phosphorescence (Prof. Maurice Curie), *review* by Prof. J. T. Randall, 483
Fluorescence 'Fatigue' (Dr. A. J. Henry), 163
Fluorescent Compounds : Marking Mosquitoes with, and Watching them by Ultra-violet Light (Dr. Rajindar Pal), 298
Fluorescent Constituents of Liver Lipid Extracts (R. Norman Jones and J. R. Jamieson), 677
Fluorescent Reaction of Tryptophane (Dr. J. V. Koštir), 266
Fluorine : Chemistry and Uses of, 462
ω-Fluorocarboxylic Acids and Derivatives : Toxic Properties of (Dr. B. C. Saunders), 179
Flying : High-Speed, and the Airport (Christmas lectures at the Institution of Civil Engineers), 824
'Flying Wing' Aircraft, 896
Focusing of Ion Beams : A Space-Charge Lens for the (Dr. D. Gabor), 89
Fodder : The Use and Misuse of Shrubs and Trees as (Imperial Agricultural Bureaux Joint Publication No. 10), 862
Fodder Grass from Central Burma : Record of an African (D. Rhind), 195
Fœtus : Synthesis of Phospholipids in the (G. Popják), 841
Folklore on the Farm, *review* by Prof. John Read, 140
Folliculinidæ (Ciliata, Heterotricha) : British (R. R. Fowell), 28
Food : The Nation's (edited by A. L. Bacharach and Theodore Rendle), *review* by Dr. Leslie J. Harris, 242
Food Industries : Pollution by Trade Wastes from (Dr. B. A. Southgate and Dr. S. H. Jenkins), 200
Food Industry : German, in War-time (Ministry of Food Exhibition), 462
Foods (Canned) : Infected Cooling Water and its Effect on the Spoilage of (T. E. Bashford), 584
Foodstuffs (Stored) : Infestation of (Food and Agriculture Organisation of the United Nations conference on), 51, 739
Footpaths and Access to the Countryside : Report of the Hobhouse Committee on, 809
Forbidden Optical Transitions : Decay of Luminescence due to (G. F. J. Garlick and A. F. Gibson), 303
Forces (H.M.) : Education in, 528
Forest Trees : British, *review* by Prof. H. G. Champion, 106
Forestry in British Colonial Territories, 764
Forests : Our (W. H. Rowe), *review* by Prof. H. G. Champion, 106
Formaldehyde (Gaseous) : Mechanism of the Oxidation of (D. W. E. Axford and Prof. R. G. W. Norrish), 537
Formation of Phospholipids in the Liver : Influence of Choline and Ethanolamine on the Rate of (Dr. A. P. Platt and R. R. Porter), 905
Formation of Seminal Fructose : Effect of Testicular Hormone on the (Dr. T. Mann and Ursula Parsons), 294
Formulæ for Ethylene Oxide and Cyclopropane (Sir Robert Robinson), 162
Formulæ and Brain Weights (Dr. Donald Sholl), 805
Four-cusped Wake : Analytical Solution of a (Dr. D. N. de G. Allen), 509
Fourier Transformer and its Application to Sound-Films : Photo-electric (Dr. D. Brown and J. W. Lyttleton), 709
'Foveal Tritanopia' (Dr. S. Karplus), 647 ; (Dr. W. D. Wright), 647
Fowl, *Gallus domesticus* : Cytology of Alimentary Tract and Associated Glands of the (Dr. K. S. Chodnik), 62
Fowl (Domestic) : Gonadal Hormones and Mineral Balance in the (Dr. R. H. Common, W. A. Rutledge and R. W. Hale), 541
Fractional Precipitation of Serum Proteins (Dr. Tage Astrup and Aksel Birch-Andersen), 637
Franklin (Benjamin) House : Formal opening of, 15
Free Amino-Acids of Plant Cells : Detection of the, by Partition Chromatography (Dr. C. E. Dent, W. Stepka and Prof. F. C. Steward), 682
Free Energy of a-Ketoglutarate and Pyruvate from Constants of the Transamination Process : Computation of the (S. Darling), 403
Free Radical Chemistry : Quantitative Aspects of (Prof. H. W. Melville), 778
Free Radicals : A New Technique for following the Attack of Metallic Mirrors by (Dr. G. Whittingham), 671
Freedom of the Press, 413
Freezing as an Aid in the Drying and Purification of Humus and Allied Materials (Dr. W. G. C. Forsyth and G. K. Fraser), 607
Freiheit : Vom Ursprung und von den Grenzen der (Gustav Bally), *review*, 315
French Scientific Library in London, 669
Frenkel's Views on the Origin of Terrestrial Magnetism (Prof. Louis B. Slichter and Dr. E. C. Bullard), 157
Frequencies of Sex-Linked Red-Green Colour Vision Defects (Dr. R. W. Pickford), 335
Frequencies of Vibration : The Prediction of Natural, *review* by Prof. W. J. Duncan, 623
Frequency of Chromosome Aberrations produced by X-Rays : Effect of Oxygen on the (Dr. J. M. Thoday and John Read), 608
Friedel-Crafts Catalysts : Polymerization of Olefins by (Dr. A. G. Evans, G. W. Meadows and Prof. M. Polanyi), 869
Friedel-Crafts Catalysts in Polymerization—Kinetic Measurements and the Role of Water (Prof. R. G. W. Norrish and K. E. Russell), 543

Frog Skin : Influence of Adenohypophysectomy on the Transfer of Salt across the (C. Barker Jørgensen), 872
Fructose and the Reducing Value of Insects' Blood (L. Levenbook), 465
Fructose (Seminal) : Effect of Testicular Hormone on the Formation of (Dr. T. Mann and Ursula Parsons), 294
Fruit and Vegetable Culture, 881
Fuel : More Warmth with Less (A. F. Dufton), 325
  Pulverized (T. F. Hurley), 318
Fuel Economy Conference of the World Power Conference (Dr. H. E. Crossley), 740
Fuel Practice, *review* by H. J. Hodsman, 5
Fuel and Chemical Industries : Hydrogenation in the (Major Kenneth Gordon), 360
Fuel and Chemistry (Dr. D. T. A. Townend), 530
Fuels, Combustion and Furnaces (Prof. John Griswold), *review* by H. J. Hodsman, 5
Functional Anatomy of the Mammal (Asst. Prof. W. James Leach), *review* by Dr. N. B. Eales, 210
Functional Development of Accessory Glands and Spermatogenesis (Dr. D. V. Davies and Dr. T. Mann), 295
Functions of a Complex Variable (Prof. Thomas M. Macrobert), third edition, *review* by J. H. Pearce, 626
Functions of Real Variables : The Theory of (Prof. Lawrence M. Graves), *review* by T. M. M., 592
Fungi (Hyphomycete) : Passive Movements of Newly Formed Acrogenous Spores in *Verticillium* and some other Genera of the (C. J. La Touche), 679
Fungistatic and Bacteriostatic Red Pigment produced by a Strain of the *Penicillium nigricans-janczewskii* Series (P. J. Curtis and J. F. Grove), 574
Fungus Parasitic on *Coptotermes curvignathus*, Holmgr. (R. A. Altson), 120
Furansulphonamides (R. Ó. Cinneide), 260
Furnaces : Fuels, Combustion and (Prof. John Griswold), *review* by H. J. Hodsman, 5
Fusaria : Production of Antibiotics by (A. H. Cook, S. F. Cox, T. H. Farmer and M. S. Lacey), 31

GALAPAGOS : Evolution on, *review* by Dr. W. S. Bullough, 853
Galileo to the Nuclear Age : From (Prof. Harvey Brace Lemon), *review* by Lieut.-Colonel H. D. Anthony, 210
Gallas domesticus : Cytology of Alimentary Tract and Associated Glands of the Fowl (Dr. K. S. Chodnik), 62
γ-Radiation from U^{239} and Np^{289} : β- and (Prof. Hilding Slätis), 579
Gamma-Ray Yield Curves of Separated Neon Isotopes Bombarded with Protons (K. J. Broström, T. Huus and J. Koch), 498
Gamma- and X-Rays on Dilute Aqueous Solutions of Acrylonitrile : Effect of (Dr. F. S. Dainton), 268
'Gammexane' : Mortality of *Aedes aegypti* Feeding on Rabbits receiving Oral (P. C. C. Garnham), 156
'Gammexane' for Insects : Inhibition of the Toxicity of (J. M. Thorp and Dr. Botha de Meillon), 264
Gas (Inert) : Emission Spectrum of Iodine Molecules in the Presence of an (Jürg Waser and Dr. K. Wieland), 643
Gas Analyser : Infra-red (Grubb, Parsons and Co.), 220
Gas Analysis : Physical Methods of (Society of Public Analysts and other Analytical Chemists, Physical Methods Group, discussion on), 441
Gas Analysis at Low Pressures (Dr. C. E. Ransley), 441
Gas Analysis by the Soap Film Method : A New Apparatus for (W. J. Gooderham), 441
Gas-Turbine Propulsion in a Naval Vessel (Metropolitan-Vickers Electrical Co., Ltd.), 392
Gaseous Formaldehyde : Mechanism of the Oxidation of (D. W. E. Axford and Prof. R. G. W. Norrish), 537
Gases : Unusual Flame (Prof. W. T. David and J. Mann), 229
Gases (Ionized) : Production of High-Frequency Energy by (J.-L. Steinberg), 833
Gastric Mucosa : Source of the Hydrogen Ions produced by (Dr. R. E. Davies, N. M. Longmuir and E. E. Crane), 506 ; (Prof. Edward J. Conway and Thomas G. Brady), 506
Gazetteer of Great Britain (Ordnance Survey), 497
Gene (Short-style) : Spontaneous Occurrence in *Lythrum salicaria* of Plants Duplex for the (Prof. R. A. Fisher and V. C. Martin), 541
Generation of Useful Power from Atomic Energy : Metallurgical Problems involved in the (Sir Wallace Akers), 182
Genetics (Edgar Altenburg), *review* by Dr. C. D. Darlington, 813
  Advances in (edited by M. Demerec), Vol. 1, *review* by Prof. C. H. Waddington, 772
  Human (Prof. Reginald Ruggles Gates), *review* by Prof. F. A. E. Crew, 274
  Recent Progress in, *review* by Prof. C. H. Waddington, 772
Genetics, Medicine and Man (H. J. Muller, C. C. Little and Laurence H. Snyder), *review* by Prof. F. A. E. Crew, 590
Geography in War and Peace (Prof. E. G. R. Taylor), 285
Geography, Life and Customs of Newfoundland-Labrador (the Eastern Part of the Labrador Peninsula) : Outlines of the (Prof. V. Tanner), *review*, 735
Geological Age—the Extreme Antiquity of Pegmatites from Manitoba (Dr. L. H. Ahrens); 874
Geological Guide-Book of Oxford, *review* by Prof. H. L. Hawkins, 243
Geological Survey of India, 1846 to 1947 (Sir Cyril S. Fox), 889
Geology : Analytical (Dr. S. I. Tomkeieff), 846 ; (A. B. Vistelius), 846
  Local, as affecting the Water Supply of Brighton (F. Needham Green), 343
  Micropalæontology in, *review* by Prof. B. Sahni, 771
Geology in the Development of the Coalfields (Dr. Murray Macgregor), 284
Geology and the Future of Coal Supplies (British Association, Section C (Geology) discussion on), 593
Geology of Oxford (Dr. W. J. Arkell), *review* by Prof. H. L. Hawkins, 243
Geomagnetic Field : Elementary Particles and the (Prof. T. G. Cowling), 847 ; (Dr. J. Barnóthy), 847
Geomagnetic Lattitudes : F_2 Ionization and (P. H. Liang), 642 ; (Sir Edward Appleton), 643
Geomagnetism and the Ionosphere (Sir Edward Appleton), 821
Geometrical Configuration of Dialkyl Naphthenes (Dr. S. F. Birch and W. J. Oldham), 368
German Food Industry in War-time (Ministry of Food Exhibition), 462
German Research in World War II (Colonel Leslie E. Simon), 884
German Scientific and Technical Papers ; Photostat Copies of, 427
German, American and British Chemical Societies' Practice : Indexing Practice—Trends in (R. Brightman), 615
Germany : British Books for, 704
  British Families Education Service in (F. J. Downs), 147
  Research in, on the Technical Application of Atomic Energy (Prof. W. Heisenberg), 211
  Science and Technical Education in, 721
Giant Panda : The, 635
Glaciological Research (Gerald Seligman), 66
Glands (Accessory) : Functional Development of, and Spermatogenesis (Dr. D. V. Davies and Dr. T. Mann), 295
Glands of the Fowl, *Gallus domesticus* : Cytology of Alimentary Tract and associated (Dr. K. S. Chodnik), 62
Glass : Reduction of Potassium Permanganate in the Presence of (C. B. Taylor), 56
  Shock Wave in (K. M. Baird), 24
Glass Tubing : Spiral Cracks in (I. C. P. Smith), 232
Glasses (Alkali Halide-Borate) : Constitution of (H. Cole), 191
Glasshouse Crops : Pathology of, 915
α-Glucerophosphate Oxidase Systems : Constitution of the Succinate and (Dr. A. O. M. Stoppani), 52
Glucose Medium : Detection of Acetic Acid in *A. niger* Growing on a (I. D. Chughtai, A. A. Pearce and Dr. T. K. Walker), 573
Glucuronic Acid during the Enzymic Hydrolysis of Conjugated Glucuronides : Formation of (Dr. G. A. Levvy), 54
β-Glucuronidase and Tissue Damage (Lynda H. M. Kerr and Dr. G. A. Levvy), 463
β-Glucuronidase and Tissue Proliferation (Lynda M. H. Kerr, Dr. G. A. Levvy and J. G. Campbell), 572
β-Glucuronidase Activity of Ox Spleen (Dr. G. T. Mills), 638
Glucuronides (Conjugated) : Formation of Glucuronic Acid during the Enzymic Hydrolsis of (Dr. G. A. Levvy), 54
Glutamic Acid : A New Adsorption Apparatus and the Separation of Aspartic and (Dr. Birger Drake), 602
l(+)Glutamic Acid in Hypoglycæmia : Effect of (W. Mayer-Gross and J. W. Walker), 334
Glutamic Acid and Pyruvic Acid : Optimum *p*H and Temperature, and Energy of Activation of the Transamination between (S. Darling), 838
Glycine and Dibenzoylphosphate : Hippuric Acid Formation from (H. Chantrenne), 603
Glycogen Phosphorolysis in Rats : Alloxan Diabetes and (Dr. D. Staehelin and Dr. W. Voegtli), 363
Glycolysis of Rat Diaphragm (Anærobic) : Effect of Injection of Adrenaline on the (Dr. J. A. Cohen), 871
Gold : Reservoirs of Water, Wheat and, *review* by Charles F. Carter, 383
Gold Medals of the Royal Society of Medicine awarded to Sir Alexander Fleming and Sir Howard Florey, 51
AuCu$_3$: Diffraction of X-Rays by the Alloy (I. G. Edmunds, R. M. Hinde and Dr. H. Lipson), 304 ; (Prof. A. J. C. Wilson), 304
Gonadal Hormones and Mineral Balance in the Domestic Fowl (Dr. R. H. Common, W. A. Rutledge and R. W. Hale), 541
Gonads and Experimental Tuberculosis (Prof. R. A. Izzo and V. H. Cicardo), 155
Governing Colonies : On (Colonel W. R. Crocker), 172
Government and Industry : Science, (Sir Edward Appleton), 850
Government Research and Development in Great Britain, 379
Government Scientific Service : Conditions in the, 392
Grain Crops in the Caribbean, 562
Granular Beds : Slip Flow in (Dr. P. C. Carman), 301
Granules : Osmophilic, in Chromatolytic Nerve Cells (Dr. P. Glees), 194
Grass (African Fodder) : Record of an, from Central Burma (D. Rhind), 195
Grasshopper Problem in North America (Dr. B. P. Uvarov), 857
Grassland and Animal Production (British Grassland Society and the British Society of Animal Production joint meeting on), 249
Great Britain : Gazetteer of (Ordnance Survey), 497
  Government Research and Development in, 379
  Nature Protection in (Dr. G. F. Herbert Smith), 457
  The Work of the Royal Institution in Physical Chemistry in (Prof. E. K. Rideal), 245
  Scientific and Technological Man-Power in, 742
  Universities of (Prof. R. C. McLean), 522
  University Expansion in, 769
  See also under Britain
Greece : Archæological Work in, 601
Grenzen der Freiheit : Vom Ursprung und von den (Gustav Bally), *review*, 315
Griseofulvin and 'Curling-Factor' : Identity of (J. F. Grove and Dr. J. C. McGowan), 574
Group to which an Individual Belongs : A Statistical Criterion to Determine the (C. Radhakrishna Rao), 835
Grouse : The Ruffed (Henry Marion Hall), *review* by Frances Pitt, 418
Growing Epithelial Tissue in *Rhodnius prolixus* (Hemiptera) : A Method for Observing (Dr. M. Lüscher), 873
Growing Plant Tissues : A Rapid Nigrosine Method for Chromosome Counts applicable to (Dr. Gösta von Rosen), 121
Growth of Isolated Pine Roots : Influence of the Sugar Concentration on the (V. Slankis), 645
Growth of Plants : Effect of 4-Chloro-2-Methyl Phenoxyacetic Acid on the Mineral Content and (A. Rhodes and Dr. W. G. Templeman), 825
Growth of Sulphate-reducing Bacteria : Autotrophic (K. R. Butlin and M. E. Adams), 154
Growth-Stimulants : Antagonistic Effect by certain, of the Tuberculostatic Activity of 5-Amino-2-butoxypyridine (H. S. Forrest, Dr. P. D'Arcy Hart and Dr. James Walker), 94
Guinea Pig : Visual Cells of the (Kevin O'Day), 648 : (Prof. Ragnar Granit), 838
Guinea Pig's Skin : Role of Dendritic Cells in the Infective Colour Transformation of (R. E. Billingham and Prof. P. B. Medawar), 61

Gyro-interaction of Radio-Waves obtained by the Pulse Method (Dr. Mario Cutolo), 834
Gyromagnetic Resonance in Ferrites (Dr. J. L. Snoek), 90

HAEMAGGLUTININS of the *Haemophilus* Group (Dr. E. V. Keogh, Dr. E. A. North and M. F. Warburton), 63
Hæmocyanin Molecules : Shape of (Dr. A. Polson and Dr. Ralph W. G. Wyckoff), 153
Hæmoglobin : Chlorocruorin and (Prof. H. Munro Fox), 825
Daphnia (Prof. H. Munro Fox), 431
Hæmolytic Disease in the Newborn : Determination of Bilirubin in the Umbilical Blood as an Aid in the Early Diagnosis of (Dr. A. Sadowski, Y. M. Bromberg and A. Brzezinski), 192
Haemophilus Group : Hæmagglutinins of the (Dr. E. V. Keogh, Dr. E. A. North and M. F. Warburton), 63
Halide-Borate Glasses (Alkali) : Constitution of (H. Cole), 191
Halides (Alkali) : Vibration Spectra of the (Prof. R. S. Krishnan), 711
Hanbury Gold Medal for 1947 of the Pharmaceutical Society of Great Britain awarded to Dr. Hans Flück, 706
Hardening of Cadmium Crystals : Thermal (Dr. C. L. Smith), 466
Hardness of Tantalum : Annealing Temperature (Prof. J. Neill Greenwood and R. H. Myers), 675
Harrison Memorial Prize to be awarded in 1947, 360
Health : The Road Back to (Ministry of Health), 220
Soils and (Dr. W. G. Ogg), 290
Health (National) : Present-Day Social and Economic Aspects of (American Philosophical Society symposium on), 360
Heat in Solids : Conduction of (Prof. H. S. Carslaw and J. C. Jaeger), *review* by Prof. L. Rosenhead, 886
Heavy Nuclei : 'Evaporation' of (D. H. Perkins), 299
Heligoland Explosion : Seismic Aspects of the (P. L. Willmore), 350
Helium (Prof. W. H. Keesom), *review* by Prof. F. E. Simon, 382
Liquid, and its Properties (Clarendon Laboratory, Oxford, conference on), 385
Helium II (Liquid) : Entropy Fluctuations in, and the Rayleigh Line (B. K. Agarwala and A. G. Chowdri), 750
Helium Film : A New Technique for Studying the (J. B. Brown and Dr. K. Mendelssohn), 670
l'herbe Conde (*Cordia macrostachya*) : Introduction of a Beetle from Trinidad into Mauritius to control (Dr. S. Maulik), 194
Hermaphrodite Teleostean Fish : Influence of Hypophyseal Hormone and of Nervous Impulses on the Colour-dress of (Dr. O. Peczenik and M. Zei), 788
Hermaphroditism in the Lower Vertebrates (Dr. W. S. Bullough), 9
Heterodera rostochiensis (Woll.) : 'DD' as a means of Controlling (George C. Martin), 720
Heterogeneity of Metaphosphate in Yeast : Physiological (E. Juni, Prof. M. D. Kamen, S. Spiegelman and J. M. Wiame), 717
High Coercivity in Ferromagnetic Materials : Interpretation of (Prof. E. C. Stoner and E. P. Wohlfarth), 650
High Energy Ranges : Nuclear Transformations in the new (Prof. Glenn T. Seaborg), 897
High Explosives : Speed Around the Initiating Point of the Detonation Wave in (W. C. F. Shepherd), 92
Spread of Detonation in (Dugald Mitchell and Stewart Paterson), 438
High Latitude : A Short-lived Solar Phenomenon in (Dr. A. D. Thackeray), 439
High-Frequency Energy by Ionized Gases : Production of (J.-L. Steinberg), 833
High-Frequency Permeability of Ferromagnetic Materials (G. Eichholz and G. F. Hodsman), 302
High Resolution Spectroscopy (Dr. S. Tolansky), *review* by Dr. D. A. Jackson, 244
High-Speed Flying and the Airport (Christmas lectures at the Institution of Civil Engineers), 824
High Vacuum (National Research Corporation and the American Chemical Society, Division of Industrial and Engineering Chemistry, symposium on), 220
High Vacuum Apparatus : Adsorption of Water Vapour in (Prof. R. G. W. Norrish and K. E. Russell), 57
Highland Naturalist Again (Dugald Macintyre), *review* by Seton Gordon, 693
Highways of the Air (Royal Geographical Society's exhibition), 863
Hinchley Memorial Lecture of the Institution of Chemical Engineers (Dr. R. V. Southwell), 462
Hippopotamus : Identification of a Calculus from a (Dr. F. A. Bannister, Dr. M. H. Hey and Dr. K. P. Oakley), 470
Hippopus hippopus (Linn.) : On the Structure of the Shells and Pearls of *Tridacna squamosa* Lam. and (Dr. A. Reyne), 653
Hippuric Acid Formation from Glycine and Dibenzoylphosphate (H. Chantrenne), 603
Histamine as a Physiological Activator of the Reticulo-Endothelial System (Dr. Miklós Jancsó), 227
Histopathology of the Skin : Atlas of (Prof. G. H. Percival, Prof. A. Murray Drennan and T. C. Dodds), *review*, 553
History of Chemistry, 84
Hog Stomach Extract (Commercial Fluid) : Persistence of a Substance with Blood Groups *A* and *O* Specificity in (M. E. Folan), 790
Hole in a Resonant Cavity : Flow of Smoke through a (F. W. Simpson), 93 ; (Dr. Robert W. Lawson), 440
Home and Factory Power Exhibition (Science Museum), 600
Hong Kong : Vegetable Cultivation in (G. A. C. Herklots), *review* by Dr. John Grainger, 658
Hop Research in Britain, 668
Hormone (Hypophyseal) : Influence of, and of Nervous Impulses on the Colour-dress of Hermaphrodite Teleostean Fish (Dr. O. Peczenik and M. Zei), 788
Hormone (Testicular) : Effect of, on the Formation of Seminal Fructose (Dr. T. Mann and Ursula Parsons), 294
Hormones : Vitamins and (edited by Prof. Robert S. Harris and Assoc. Prof. Kenneth V. Thimann), Vol. 4, *review* by Dr. Leslie J. Harris, 242
Hormones (Oestrogenic) : Nature of the C/D-Ring Union in the (Dr. C. W. Shoppee), 64
Horticulture : University Teaching in Agriculture and, 151
Host-Plant of *Crioceris merdigera* : Willow as (Dr. S. Maulik), 609
Houses (African) : Economic Control of the Relapsing Fever Tick in (W. F. Jepson), 874
Hughes Medal for 1947 of the Royal Society awarded to Prof. J. F. Joliot, 704, 841
Human Blood Groups : Dominance and Recessiveness in the (Dr. A. E. Mourant), 353
Human Carboxyhæmoglobin : Crystal Structure of (Dr. M. F. Perutz and Olga Weisz), 786
Human Ear : Transient Reception and the Degree of Resonance of the (Dr. R. J. Pumphrey and T. Gold), 124
Human Factor : Centralized Planning and the, 1
Human Foot : Research Fellowship for work on the structure of the (University College London and the British Boot, Shoe and Allied Trades Research Association), 497
Human Genetics (Prof. Reginald Ruggles Gates), *review* by Prof. F. A. E. Crew, 274
Human *Iso*-Agglutinin subdividing the *MN* Blood Groups : A New (Dr. R. J. Walsh and Miss Carmel M. Montgomery), 504
Human Oddities : Some (E. J. Dingwall), *review*, 39
Human Retina : Some Fatigue Effects on the, produced by using Coloured Lights (Prof. H. Hartridge), 538
Human Servo : The Design and Performance of the (Dr. J. A. V. Bates), 341
Human Welfare : Relation of Diseases of the Lower Animals to (New York Academy of Sciences, Section of Biology, conference on), 237
Humanism : Thermodynamics and, *review* by Dr. J. A. V. Butler, 72
Humus and Allied Materials : Freezing as an Aid in the Drying and Purification of (Dr. W. G. C. Forsyth and G. K. Fraser), 607
Huyghens' Construction : Total Internal Reflexion and—the Immersion Grating (Dr. G. L. Rogers), 25
Hyaluronidase from Reptilian Testes : Absence of (G. I. M. Swyer), 433
Hydration : Excessive, in an Animal with an Open Type of Circulation (A. E. Needham), 755
Hydrocarbon Gases : The Analysis of, by Low Temperature Distillation (J. H. D. Hooper), 441
Hydrocyanic Acid and Poliomyelitis (R. R. Scobey), 359
Hydrodynamics of Non-Newtonian Fluids (R. S. Rivlin), 611
Hydrogen in Combustion Systems : Use of a Palladium Tube Technique in the Study of the Role of (J. R. Arthur and E. Sterling), 869
Hydrogen Atoms with Solid Carbon : Reaction of (Prof. G. M. Harris and A. W. Tickner), 871
Hydrogen Bond in Potassium Hydrogen Fluoride : Nature of the (D. Polder), 870
Hydrogen Ions produced by Gastric Mucosa : Source of the (Dr. R. E. Davies, N. M. Longmuir and E. E. Crane), 506 ; (Prof. Edward J. Conway and Thomas G. Brady), 506
Hydrogen Peroxide : Reaction between Catalase and (Dr. P. George), 41
Hydrogenation in the Fuel and Chemical Industries (Major Kenneth Gordon), 360
Hydrolysis of Bi^{3+} : Oxygen Bridging—a New Type of Ionic Equilibrium (Fredrik Granér and Dr. Lars Gunnar Sillén), 715
Hydrolysis of Cellulose by *Coniophora cerebella* : Enzymatic (Prof. F. F. Nord and J. C. Vitucci), 261
Hydrolysis of Conjugated Glucuronides : Formation of Glucuronic Acid during the Enzymic (Dr. G. A. Levvy), 54
Hydrotropic Substances : Influence of, on the Sol/Gel Transformation of Blood Plasma *in vitro* (Dr. Ch. Wunderly), 228
Hydroxy Compounds : Interaction of Thionyl Chloride and (D. Libermann), 903
Hydroxylammonium Chloride and Bromide : Crystal Structure of (Miss Bodil Jerslev), 641
Hyper- and Avitaminosis in Micro-organisms (Dr. M. N. Meissel), 269
Hypertension after Bilateral Nephrectomy in the Rat (E. Braun-Menéndez and Prof. U. S. v. Euler), 905
Hypertonic Solutions of Sodium Chloride and of Urea : Response of Newborn Children to (R. F. A. Dean and Prof. R. A. McCance), 904
Hyphomycete Fungi : Passive Movements of Newly Formed Acrogenous Spores in *Verticillium* and some other Genera of the (C. J. La Touche), 679
Hypoglycæmia : Effect of *l*(+)Glutamic Acid in (W. Mayer-Gross and J. W. Walker), 334
Hypophyseal Hormone and of Nervous Impulses on the Colour-dress of Hermaphrodite Teleostean Fish : Influence of (Dr. O. Peczenik and M. Zei), 788
Hypophysectomy on Blood-Sugar Levels after Injection of Alloxan : Effects of Anterior Pituitary Extract and (Mervyn Griffiths), 758
Hypothetical Alternative Energy Sources for the 'Second Meson' Events (Dr. F. C. Frank), 525

IDENTIFICATION of a Calculus from a Hippopotamus (Dr. F. A. Bannister, Dr. M. H. Hey and Dr. K. P. Oakley), 470
Identification of Creatine by Partition Chromatography (G. A. Maw), 261
Identity of Griseofulvin and 'Curling-Factor' (J. F. Grove and Dr. J. C. McGowan), 574
Ill in America : The Mentally (Albert Deutsch), *review* by Dr. G. W. T. H. Fleming, 279
Immigration into Britain of Continental Butterflies, 359
Immunological Investigations : Use of Radioactive Isotopes in (Dr. J. C. Boursnell, H. M. Dewey, Dr. G. E. Francis and Prof. A. Wormall), 339
Incentives in Industry (British Association, Sections F (Economics) and J. (Psychology) symposium on), 587
Incidence of the Sun's Rays : Angle of (P. J. H. Unna), 713
Incubation : Rook-Behaviour during (C. M. Ogilvie), 563
Indexing Practice—Trends in German, American and British Chemical Societies' Practice (R. Brightman), 615
India : Anthropological and Archæological Work in, 669
India (New) : Science in the (D. N. Wadia), 253
India, 1846 to 1947 : The Geological Survey of (Sir Cyril S. Fox), 889
India and Pakistan : The Profession of Chemistry in, 743
Indian Archipelago : Peoples of the, *review* by Prof. J. H. Hutton, 732
Indians of the South-Eastern United States (John R. Swanton), 898

Indicator in Acid-Alkali Titrations : Mercurochrome as an (Dr. J. W. Airan), 88
Individual : Society and the (British Social Hygiene Council conference on), 706
Individual Activity of Ants (Derek Wragge Morley), 122
Individual Belongs : A Statistical Criterion to Determine the Group to which an (C. Radhakrishna Rao), 835
Induced Polycythæmia by *l*-Ascorbic Acid in Albino Mice (Jui-Ming Chen), 681
Industrial Development in Scotland : Scientific Research and, 341
Industrial Productivity : Committee on, 896
Industrial Research : The Organisation of (Dr. R. P. Russell), 547
Industrial Research (Scientific and) : Organisation for, 883
Industrial Research in British Industry : Scientific and (Federation of British Industries), 770
Industrial Utilization of Agricultural Products and of Seaweed (Irish Chemical Association and the Dublin Section of the Royal Institute of Chemistry colloquium on), 373
Industry : Co-operative Research in (Dr. D. W. Hill), *review* by R. Brightman, 346
  Dutch Pioneers in Science and, *review* by Lieut.-Colonel Ernest Tillotson, 449
  Incentives in (British Association, Sections F (Economics) and J (Psychology) symposium on), 587
  Physical Science in Art and (Dr. E. G. Richardson), second edition, *review* by F. Ian G. Rawlins, 315
  Science, Government and (Sir Edward Appleton), 850
  'Sponsored' Research for (Sir Stafford Cripps), 150
  Standardization in (Percy Good), 618
  X-Rays in Research and (Dr. H. Hirst), second edition, *review* by Dr. W. A. Wood, 142
Industry (British) : Scientific and Industrial Research in (Federation of British Industries), 770
Industry in Scotland : Research and the Progress of (Federation of British Industries regional conference on), 341
Industry and Employment in Scotland (Scottish Office report on), 341
Inequality of (III) X-Ray Reflexions in Diamond (Dr. W. A. Wooster and G. L. Macdonald), 500
Inert Gas : Emission Spectrum of Iodine Molecules in the Presence of an (Jürg Waser and Dr. K. Wieland), 643
Infected Cooling Water and its Effect on the Spoilage of Canned Foods (T. E. Bashford), 584
Infection by the Vole Acid-Fast Bacillus : Notes on the Morphology of (Dr. A. H. T. Robb-Smith), 687
Infective Colour Transformation of Guinea Pig's Skin : Role of Dendritic Cells in the (R. E. Billingham and Prof. P. B. Medawar), 61
Infestation of Stored Foodstuffs (Food and Agriculture Organisation of the United Nations conference on), 51, 739
Influence of Choline and Ethanolamine on the Rate of Formation of Phospholipids in the Liver (Dr. A. P. Platt and R. R. Porter), 905
Influence of Water on the Lubrication of Metals (E. D. Tingle), 710
Influenza Group (Mumps) : Mucin as Substrate of Enzyme Action by Viruses of the (Dr. F. M. Burnet, J. F. McCrea and S. G. Anderson), 404
Information on Atomic Energy : Release of, 445
Information and Knowledge : Communication of, 621
Infra-Red Analysis : Use of Polarized Radiation in (Dr. G. B. B. M. Sutherland and A. Vallance Jones), 567
Infra-Red Gas Analyser (Grubb, Parsons and Co.), 220
Infra-Red Radiation : Polarized, as an Aid to Crystal Analysis (D. A. Crooks), 17
Infra-Red Radiation (Polarized) : Absorption Spectra with (J. Mann and Dr. H. W. Thompson), 17
Infra-Red Solar Spectrum : Use of the Cathode Ray Oscillograph for Studying the near (A. U. Momin), 130
Infra-Red Spectroscopy : Lead Selenide Cells for (D. E. Blackwell, O. Simpson and Dr. G. B. B. M. Sutherland), 793
Infra-Red Spectrum and Molecular Structure of Phthiocerane (S. Ställberg-Stenhagen and Prof. E. Stenhagen, and N. Sheppard, Dr. G. B. B. M. Sutherland and A. Walsh), 580
Inheritance : Mendelian, in New Zealand Romney Sheep (Dr. F. W. Dry, A. Stewart Fraser and G. M. Wright), 646
Inhibition of the Toxicity of 'Gammexane' for Insects (J. M. Thorp and Dr. Botha de Meillon), 264
Initial Parenchyma Cells in Dicotyledonous Woods (K. A. Chowdhury), 609
Initiating Point of the Detonation Wave in High Explosives : Speed Around the (W. C. F. Shepherd), 92
Injection of Adrenaline on the Anærobic Glycolysis of Rat Diaphragm : Effect of (Dr. J. A. Cohen), 871
Injection of Alloxan : Effects of Anterior Pituitary Extract and Hypophysectomy on Blood-Sugar Levels after (Mervyn Griffiths), 758
Innervation of Cutaneous Pain 'Spots' : Significance of Multiple, in relation to the Quality of Pain Sensibility (Dr. G. Weddell, D. C. Sinclair and W. H. Feindel), 27
Inoculation of an Equine Strain of Encephalomyelitis Virus : Chick Embryos Surviving the (Dr José J. Monteverde and Dr. Domingo H. Simeone), 680
Ionized Gases : Production of High-Frequency Energy by (J.-L. Steinberg), 833
Ionosphere : Geomagnetism and the (Sir Edward Appleton), 821
Insect Book for the Pocket (Edmund Sandars), *review* by A. D. I., 553
Insecticidal Effect of Surface Deposits of D.D.T. on Mud (A. B. Hadaway and F. Barlow), 363
Insecticides and Weed-killers : Development of, 743
Insects : The Corpus Allatum and the Control of Metamorphosis in (Dr. V. B. Wigglesworth), 16
  Inhibition of the Toxicity of 'Gammexane' for (J. M. Thorp and Dr. Botha de Meillon), 264
  Protective Coloration in, and its Interpretation (Prof. G. D. Hale Carpenter), 343
  Regulation of the Sodium-Potassium Ratio in (Dr. G. J. Boné), 679
Insects' Blood : Fructose and the Reducing Value of (L. Levenbook), 465
Insemination of Livestock (Artificial) : Stockbreeding and the (V. K. Milovanov and I. I. Sokolovskaya), translated by Dr. A. G. Morton, *review* by John Hammond, 209
Insulin : Oxidation of, by Performic Acid (Dr. F. Sanger), 295
Insulin (Oxidized): Adsorption Analysis of, (Prof. A. Tiselius and F. Sanger), 433
Integration : The Final, *review* by Prof. E. D. Adrian, 623
Integrative Action of the Nervous System (Sir Charles Sherrington), *review* by Prof. E. D. Adrian, 623
Intensity of Solar Radiation on 175 Mc./s and 80 Mc./s : Relation between the (M. Ryle and D. D. Vonberg), 157
Interaction of Styrene with Magnesium Perchlorate and other Salts (H. S. Lilley and G. L. Foster), 131
Interaction of Thionyl Chloride and Hydroxy Compounds (D. Libermann), 903
Interaction Terms in Molecular Vibrations (Prof. C. A. Coulson, Dr. Jules Duchesne and C. Manneback), 793
International Collaboration : The Social Sciences as a Factor in, 103
International Collection of Pure Chemical Substances, 822
International Conference on Colour Vision, 664
International Conference on Soil Mechanics and Foundation Engineering : Second, 360
International Conference for the Protection of Nature (Dr. J. Ramsbottom), 320
International Congress of Pure and Applied Chemistry : Eleventh, 14, 246
International Congress of Experimental Cytology : Sixth, 443
International Congress on Large Dams, 784
International Congress on the Family and on Population, 183
International Congress for Microbiology : Fourth (Dr. Ralph St. John-Brooks), 596
International Congress for Technical Education at the Technische Hochschule, Darmstadt (James T. Kendall), 721
International Congress of Zoology : Thirteenth, 326
International Control of Atomic Energy (Association of Scientific Workers discussion on), 436
International Control of Atomic Energy, 460
International Exhibition of Scientific Research and Industry, 766
International Physiological Congress : Seventeenth, 248
International School in Social Biology (British Social Hygiene Council), 803
International Standards and Units of Radioactivity, 778
International Timber Conference (Report of the Food and Agricultural Organisation of the United Nations), 878
International Understanding : Mass Education and, 689
Interpretation of the Exchange of Radio-Sodium in Isolated Muscle (Dr. Hans H. Ussing), 262
Interpretation of High Coercivity in Ferromagnetic Materials (Prof. E. C. Stoner and E. P. Wohlfarth), 650
Interpretation of Radio Echoes from Polar Auroras (N. Herlofson), 867
Interstellar Matter : Some Phenomena connected with (Prof. J. H. Oort), 203
Intramural Vessels in the Retina (*Vasa vasorum*), (Prof. Arnold Loewenstein), 124
Inventions, Patents and Monopoly (Peter Meinhardt), *review* by Sir William Jarratt, 482
Inverse Sampling : Errors of Estimation in (D. J. Finney), 195
Invertase (Prof. Carl Neuberg and Dr. Irene S. Roberts), *review*, 279
Invertebrates (Danish Marine Bottom) : Reproduction and Larval Development of (Dr. Gunnar Thorson), 766
Iodine Molecules in the Presence of an Inert Gas : Emission Spectrum of (Jürg Waser and Dr. K. Wieland), 643
Iodine Solutions : Colour of (Dr. F. Fairbrother), 87
Ion Beams : A Space-Charge Lens for the Focusing of (Dr. D. Gabor), 89
Ion Source : A Radio-Frequency, with High Percentage Yield of Protons (J. G. Rutherglen and J. F. I. Cole), 545
Ionic Equilibrium : Hydrolysis of Bi^{3+}. Oxygen Bridging— New Type of (Fredrik Granér and Dr. Lars Gunnar Sillén), 715
Ionization of β-particles in Alcohol Vapour and Argon : Primary (Dr. S. C. Curran and J. M. Reid), 866
Ionization (Meteoric) : Meteors, Comets and (Physical Society discussion on), 76
  Radio Reflexions from (Physical Society discussion on), 74
Ireland (Northern) : Agriculture in, 862
Irradiation Product from Stilbamidine : Constitution of the (Dr. J. D. Fulton and Dr. J. D. Dunitz), 161
Island : I Know an (R. M. Lockley), *review* by Frances Pitt, 735
iso-Agglutinin : A New Human, subdividing the *MN* Blood Groups (Dr. R. J. Walsh and Miss Carmel M. Montgomery), 504
iso-Amidone: Optical Isomers of Amidone, with a Note on (R. H. Thorp, E. Walton and P. Ofner), 605
iso-Octenes : Action of Per-Acids on the (Dr. J. G. M. Bremner), 575 ; (Dr. W. J. Hickinbottom), 576
Isobutene : Low-Temperature Polymerization of, by Titanium Chloride (Dr. P. H. Plesch), 868
Isolated Muscle : Interpretation of the Exchange of Radio-Sodium in (Dr. Hans H. Ussing), 262
Isolated Pine Roots : Influence of the Sugar Concentration on the Growth of (V. Slankis), 645
Isolation in Botanical Research : Co-operation versus (Dr. I. W. Bailey), 804
Isolation of a Quadrivalent Rhodium Complex (Dr. F. P. J. Dwyer and R. S. Nyholm), 502
'Isomantle' for the Heating of Flasks (Towers and Co., Ltd.), 862
Isomeric Trithioaldehydes : The (Dr. G. M. Bennett), 502
Isotherms : Adsorption, from Chromatographic Measurements (Dr. E. Glückauf), 301
Isotope of Tungsten : A New (Dr. G. Wilkinson), 864
Isotopes (Radioactive) : Use of, in Immunological Investigations (Dr. J. C. Boursnell, H. M. Dewey, Dr. G. E. Francis and Prof. A. Wormall), 339
Isotopic Analysis : Elementary—Determination of Nitrogen (A. D. Hirshenbaum, S. G. Hindin and A. V. Grosse), 187

JAW of the Male Sterkfontein Ape-man (Dr. R. Broom and J. T. Robinson), 153
  See *also under* Sterkfontein
Jewellery Industry : Research in the, 863

'Jobbins' : A New Blood Group Antigen (B. E. Gilbey), 362
Juvenile Delinquency : Biology and (Dr. E. R. Frey), 803

KALINOWSKI (Stanislaw) and the Swider Geophysical Observatory, 359
Kelvin Gold Medal for 1947 awarded to Air Commodore F. G. Whittle, 564
Kent and Sussex : Some Orchids of (E. J. Bedford), 343
Kenya : A Disease of Pyrethrum in (Dr. R. M. Nattrass), 120
Keratin : Chemical Constitution of (Dr. H. Lindley), 190
Keratin and Nylon : Effect of Polar Vapours on the Direct-Current Conductance of (G. King and J. A. Medley), 438
α-Ketoglutarate and Pyruvate : Computation of the Free Energy of, from Constants of the Transamination Process (S. Darling), 403
Kew : Recordings at, of the Brest Explosion (J. M. Stagg), 184
Kidney Efficiency : 'Water Excretory Threshold' as a Measurement of (J. A. Barclay, R. A. Kenney and Dr. W. T. Cooke), 432
Kinetics of the Bacterial Cell : The Chemical (Prof. C. N. Hinshelwood), *review* by Dr. J. Monod, 105
Kitchen : Bacteriology in the (Dr. Irene Hutchinson), 50
Knife for Causing Brain Lesions : An Ensheathed Rotating (Dr. P. Glees, P. D. Wall and T. A. Wright), 365
Knowledge : Communication of Information and, 621
Knowledge (Scientific) : Publication and Classification of (Association of Scientific Workers, Cambridge Senior Branch, conference on), 496, 649

LABILE Molecule : The (Faraday Society discussion on), 326, 778
Laboratory : Technique for Rearing Thrips in the (Dr. E. McC. Callan), 432
Laboratory Equipment : Catalogue of (Griffin and Tatlock, Ltd.), 635
Laboratory Technicians : Education and Training of, 635
Labrador Peninsula : Outlines of the Geography, Life and Customs of Newfoundland-Labrador, the Eastern Part of the (Prof. V. Tanner), *review*, 735
Lace Industry : Scientific Approach to the, 879
Lactating Rats (Adrenalectomized) : Decrease in the Arginase of the Liver and Mammary Gland in, as compared with Pair-fed Controls (Dr. S. J. Folley and A. L. Greenbaum), 364
Lakes and Streams : Some Aspects of the Bacteriology of (Dr. C. B. Taylor), 584
Land (Tillage) : Survey of Mineral Deficiencies on (Dr. William Plant), 336
Land in Britain : Use of the, 515
Land Classification : Problems of Soil and (British Society of Soil Science conference on), 686
Land Utilization in Britain, 809
Language and Culture : Sociological Significance of, 205
Larva of *Aedes aegypti* L. : Further Observations on the Nutritional Requirements of the (Dr. L. Golberg and Dr. B. De Meillon), 582
Larval Development of Danish Marine Bottom Invertebrates : Reproduction and (Dr. Gunnar Thorson), 766
Latitude (High) : A Short-lived Solar Phenomenon in (Dr. A. D. Thackeray), 439
Lattice : Random Association of Points on a (P. V. Krishna Iyer), 714
Lattice Strains in Plastically Deformed Metals : Residual (G. B. Greenough), 258
Law-making in Science (Society for Visiting Scientists discussion on), 530
Lead on White Rats : Nephrotoxic and Renotropic Effects of, and its Prevention by *B.A.L.* (Dr. Hugo Chiodi and Rodolfo A. Sammartino), 680
Lead Ions : Adsorption Isotherm of a Photographic Emulsion for Uranyl and (Dr. E. Broda), 231
Lead Selenide : Conductivity of Evaporated Films of (O. Simpson), 791
Lead Selenide Cells for Infra-Red Spectroscopy (D. E. Blackwell, O. Simpson and Dr. G. B. B. M. Sutherland), 793
Leaf Heteromorphism and Photoperiods in *Sesamum orientale* L. (Prof. J. C. Sen Gupta and Santosh Kumar Payne), 510
Leaves of Aquatic Plants : Diffusion of Dissolved Substances through Thalli and (Prof. E. Steemann Nielsen), 376
Leeches (Antarctic) : Two New (August Brinkmann, Jun.), 756
Legion of Honour : Cross of the Chevalier of the, awarded to Dr. E. Ashworth Underwood, 462
Length of Day : Influence of Variation in, upon the Breeding Season in Sheep (N. T. M. Yeates), 429
Lens for the Focusing of Ion Beams : A Space-Charge (Dr. D. Gabor), 89
Leverhulme Research Fellowships : Awards for 1947, 119
Leverhulme Research Scholarships : To be awarded by the Royal College of Surgeons, 530
Liberty and Peace : Science, (Aldous Huxley), 172 ; *review* by R. Brightman, 733
Libraries and their Use, 292
Library of the World : A Central, 562
Lie Groups, I : Theory of (Claude Chevalley), *review* by Dr. A. G. Walker, 854
Life (Daily) : Chemical Developments and our, 35
Life in the World : Science and (George Westinghouse Centennial Forum, May 16–18, 1946), Vol. I, Science and Civilization ; The Future of Atomic Energy ; Vol. 2, Transportation—a Measurement of Civilization ; Light, Life and Man ; Vol. 3, A Challenge to the World ; *review* by W. L. Sumner, 141
Life and Customs of Newfoundland-Labrador (the Eastern Part of the Labrador Peninsula) : Outlines of the Geography, (Prof. V. Tanner), *review*, 735
Light : Radiation Damping Theory and the Propagation of (B. Ferretti and Prof. R. E. Peierls), 531
Light (Polarized) : Starch Hydrolysis by (Dr. Elizabeth S. Semmens), 669
Light Units (Electrical and) : Introduction of New (Sir Charles Darwin), 167
Lightning Discharges : Occurrence of Upward Streamers in (R. H. Golde), 395
Lights (Coloured) : Some Fatigue Effects on the Human Retina produced by using (Prof. H. Hartridge), 538
Linear Accelerator for Electrons : Travelling-Wave (D. W. Fry, R. B. R.-S. Harvie, L. B. Mullett and W. Walkinshaw), 351
Linnean Herbarium : A Catalogue of the (compiled and annotated by Spencer Savage), *review* by Dr. W. B. Turrill, 73
Lipid Extracts (Liver) : Fluorescent Constituents of (R. Norman Jones and J. R. Jamieson), 677
Lipochromes in the Ova of *Pila* (Dr. Alex Comfort), 333
Lipoids (Cancerous and Non-Cancerous) : Fluorescence of (H. S. Penn and Prof. Joseph Kaplan), 18
Liquid Explosives : Properties of (R. G. Vines), 400
Liquid Helium and its Properties (Clarendon Laboratory, Oxford, conference on), 385
Liquid Helium II and the Rayleigh Line : Entropy Fluctuations in (B. K. Agarwala and A. G. Chowdri), 750
Liquids : Absorption of Ultrasonic Waves in (Acoustics Group of the Physical Society discussion on), 913
  A Pulse Method for the Measurement of Ultrasonic Absorption in—Results for Water (J. M. M. Pinkerton), 128
  Surface Tension in (C. Gurney), 166
Li_2, Na_2, K_2 and NaK : Absorption Bands of (Dr. R. W. B. Pearse and S. P. Sinha), 159
Little (Arthur Dehon) Memorial Lecture (Sir Edward Appleton), 850
Littorina saxatilis (Olivi) : Oviparity in (G. Seshappa), 335
Liver : Influence of Choline and Ethanolamine on the Rate of Formation of Phospholipids in the (Dr. A. P. Platt and R. R. Porter), 905
Liver Cell in Pregnancy : Composition and Structure of the (Dr. H. W. Kosterlitz and Rosa M. Campbell), 676
Liver Extracts : A Microbiological Method of Standardizing (Prof. S. Mahdihassan and Vasudev M. Bakshi), 404
Liver Extracts and Urine : Pteroylglutamic Acid in (Dr. L. Golberg, Dr. B. De Meillon and J. F. Murray), 22
Liver Lipid Extracts : Fluorescent Constituents of (R. Norman Jones and J. R. Jamieson), 677
Liver and Mammary Gland in Adrenalectomized Lactating Rats as compared with Pair-fed Controls : Decrease in the Arginase of the (Dr. S. J. Folley and A. L. Greenbaum), 364
Livestock : Raising (Walter H. Peters and Prof. George P. Deyoe), *review* by Prof. J. E. Nichols, 347
  Stockbreeding and the Artificial Insemination of (V. K. Milovanov and I. I. Sokolovskaya), translated by Dr. A. G. Morton, *review* by John Hammond, 209
Livestock Improvement in U.S.S.R., *review* by John Hammond, 209
Local Scientific Societies (Dr. J. Ramsbottom), 290
Locality for *Cyprinodon dispar* Rueppel : A New (Dr. H. Mendelsohn), 123
Location of the Currents causing the Solar and Lunar Diurnal Magnetic Variations (Dr. D. F. Martyn), 535
Locust (*Nomadacris septemfasciata*) in Africa, 1927–1945 : Migrations and Breeding of the Red (V. Morant), 67
Locust (*Schistocera gregaria*) in Eastern Africa: Seasonal Breeding and Migrations of the Desert (Z. Waloff), 67
Locust (Red) : The Habits and Control of the, in Outbreak Areas and Elsewhere (A. P. G. Michelmore), 67
Locusts : Recent Research on (Dr. A. D. Imms), 67
London : American Scientific Mission for, 633
  French Scientific Library in, 669
Loom of Prehistory (A. J. H. Goodwin), 393
Low-Angle X-Ray Scattering : Correction of Measurements of (Dr. A. Guinier and G. Fournet), 501
Low-Pressure Amplifier and Electro-pneumatic Converter (Negretti and Zambra, Ltd.), 325
Low-Temperature Cabinet : A Fully Automatic (J. and E. Hall, Ltd.), 359
Low-Temperature Physics (American Physical Society symposium on), 530
Low-Temperature Physics in North America (Prof. J. F. Allen), 736
Low-Temperature Polymerization of Isobutene by Titanium Chloride (Dr. P. H. Plesch), 868
Low Temperatures : Nuclear Magnetic Resonance at (B. V. Rollin, J. Hatton, A. H. Cooke and R. J. Benzie), 436
Lubrication of Metals : Influence of Water on the (E. D. Tingle), 710
Luminescence due to Forbidden Optical Transitions : Decay of (G. F. J. Garlick and A. F. Gibson), 303
Luminescence and Absorption Spectra of Ruby : Raman Spectrum of Alumina and the (Dr. R. S. Krishnan), 26
Lunar Diurnal Magnetic Variations : Location of the Currents causing the Solar and (Dr. D. F. Martyn), 535
Lung of an American Bison : Occurrence of *Aspergillus fumigatus* Fresen, in the (Dr. R. E. Rewell and Dr. G. C. Ainsworth), 362
Luzula purpurea Link : Chromosome Number and Behaviour in (Nydia Malheiros and Duarte de Castro), 156
Lymph (New York Academy of Sciences conference on), 845
Lymphocyte : Function of the (Dr. O. A. Trowell), 845
Lythrum salicaria : Spontaneous Occurrence in, of Plants Duplex for the Short-style Gene (Prof. R. A. Fisher and V. C. Martin), 541

MACH Waves in Shock Wave Systems from Detonating Explosives (D. W. Woodhead and R. Wilson), 672
Machines : Calculating (Prof. D. R. Hartree), *review*, 142
Macrofotografia : Microfotografia e (Prof. Edgardo Baldi), *review* by Dr. H. H. Hopkins, 553
Magnesium Benzene Sulphonates (Zinc and) : Crystal Structures of (J. M. Broomhead and A. D. I. Nicol), 795
Magnesium Perchlorate and other Salts : Interaction of Styrene with (H. S. Lilley and G. L. Foster), 131
Magnet : A Floating (Prof. V. Arkadiev), 330
Magnetic Energy Levels in Chrome Alum : Paramagnetic Resonance and (D. M. S. Bagguley and Dr. J. H. E. Griffiths), 532
Magnetic Field : Penetration of, into Superconductors (E. Laurmann and Dr. D. Shoenberg), 747
Magnetic Field (Earth's) : Blackett's Fundamental Theory of the (A. L. Hales and D. I. Gough), 746
Magnetic Field of the Moon ? : The (Prof. S. Chapman), 395
Magnetic Moment of the Deuteron : Nuclear Forces and the (Prof. H. S. W. Massey and T[illegible]-Ming Hu), 794

Magnetic Relaxation : Nuclear (N. Bloembergen, E. M. Purcell and R. V. Pound), 475
Magnetic Resonance : Nuclear, at Low Temperatures (B. V. Rollin, J. Hatton, A. H. Cooke and R. J. Benzie), 436
Magnetic Variations : Location of the Currents causing the Solar and Lunar Diurnal (Dr. D. F. Martyn), 535
Magnetism (Terrestrial) : Frenkel's Views on the Origin of (Prof. Louis B. Slichter and Dr. E. C. Bullard), 157
Magnetization : Probabilities of (G. C. Richer), 256
Magnets (Elementary) : Oscillations of (Prof. V. Arkadiew), 397
Malaya : Agriculture in, 50
Malaysia : The Peoples of (Fay-Cooper Cole), *review* by Prof. J. H. Hutton, 732
Malonate and Plant Respiration (Prof. J. S. Turner and V. Hanly), 296 ; *erratum*, 530
Mammal : Functional Anatomy of the (Asst. Prof. W. James Leach), *review* by Dr. N. B. Eales, 210
Mammals : Tryptophane as Precursor of Nicotinamide in (Dr. P. Ellinger and M. M. Abdel Kader), 675
Mammary Gland in Adrenalectomized Lactating Rats as compared with Pair-fed Controls : Decrease in the Arginase of the Liver and (Dr. S. J. Folley and A. L. Greenbaum), 364
Man : Brain and Body Weight in (Prof. E. W. Count), 805
  Genetics, Medicine and (H. J. Muller, C. C. Little and Laurence H. Snyder), *review* by Prof. F. A. E. Crew, 590
  Metabolism of Synthetic Œstrogens in (Dr. A. E. Wilder Smith), 787
  Subdivisions of the *MN* Blood Groups in (Dr. R. J. Walsh and Ruth Sanger), 505
Man of Science : Education of the (Sir John Lennard-Jones), 520
Man's Adaptability (Prof. S. J. F. Philpott), 288
Man-Power in Great Britain : Scientific and Technological, 742
Management : Education for (Report of a Special Committee of the Ministry of Education), 69
  Scientific Organisation and, 729
  Selection for (British Association for the Advancement of Science, Section J (Psychology) discussion on), 512
  Training for, 69
Management of Research, 547
Manitoba : Geological Age—the Extreme Antiquity of Pegmatites from (Dr. L. H. Ahrens), 874
Manual Control : The Nature of the Operator's Response in (Prof. A. Tustin), 341
Marconi Jubilee and Congress in Rome, 743
Marine Bottom Invertebrates (Danish) : Reproduction and Larval Development of (Dr. Gunnar Thorson), 766
Market Research (Manchester Joint Research Council conference on), 686
Marking Mosquitoes with Fluorescent Compounds and Watching them by Ultra-violet Light (Dr. Rajindar Pal), 298
Marriage : Army Education Courses—Preparation for (R. Weatherall), 684
Marrow Cultures (Bone) : Maturation of Megaloblasts in (Prof. St. Rusznyák, S. Löwinger and L. Lajtha), 757
Mass Education and International Understanding, 689
Mathematical Aids for Engineers (Raymond W. Dull), *review*, 349
Mathematical Physics : Methods of (Dr. Harold Jeffreys and Dr. Bertha Swirles Jeffreys), *review*, 139
Mathematical Statistics : Introduction to (Assoc. Prof. Paul G. Hoel), *review* by David G. Kendall, 625
Mathematics : Applied, for Engineers and Physicists (Dr. Louis A. Pipes), *review* by E. N. Fox, 552
Mathematics and Physics : The Union of, *review*, 139
Mathematics or Physics ?, *review* by Prof. L. Rosenhead, 886
Matter : Decay of Negative Mesons in (Dr. H. Fröhlich), 255
Matter-Radiation Cycle in the Cosmos (and the Second 'Law') : The—the Sun's Equilibrium (Alfred Lauck Parson), 906
Maturation of Megaloblasts in Bone Marrow Cultures (Prof. St. Rusznyák, S. Löwinger and L. Lajtha), 757
Mauritius : Introduction of a Beetle from Trinidad into, to Control *l'herbe Conde* (*Cordia macrostachya*), (Dr. S. Maulik), 194
Measurable and the Non-measurable : The (Dr. A. Vibert Douglas), 908 ; (Prof. Herbert Dingle), 908
Measurements of Low-Angle X-Ray Scattering : Correction of (Dr. A. Guinier and G. Fournet), 501
Measurements of Negative Adsorption : Calculation of Surface Areas from (Dr. R. Kenworthy Schofield), 408
Measurements of Short Life-Periods of Radioactive Sources : Application of the Cathode Ray Oscillograph to (Dr. S. Rowlands), 191
Mechanical Degradation of Large Molecules (William John Morris and Dr. Robert Schnurmann), 674
Mechanical Properties of Metals (Summer School and conference at the University of Bristol on), 696
Mechanics of Road-making Materials, *review*, 518
Mechanism for Colour Vision : A Possible Central (Prof. W. E. Le Gros Clark and L. Chacko), 123
Mechanism of Enzyme Specificity in the Domain of Carbohydrates (Dr. A. Gottschalk), 113
Mechanism of Ferromagnetic Dispersion (J. B. Birks), 535
Mechanism of the Oxidation of Gaseous Formaldehyde (D. W. E. Axford and Prof. R. G. W. Norrish), 537
Mechanism of Wood Decay : Enzyme Studies on the (Prof. F. F. Nord and J. C. Vitucci), 224
Medal of Freedom awarded by the Government of the United States to W. G. Busbridge, W. J. Challens and Prof. C. N. Hinshelwood, 513
Medal of Freedom with Bronze Palm awarded by the Government of the United States to Prof. J. D. Bernal, Dr. Henry G. Booker, A. Lang Brown, S. J. Grose, Dr. Hubert G. Hopkins, Dr. E. Talbot Paris, (291), Dr. William J. Richards, William Ross and John M. C. Scott, 513
Medal of Freedom with Silver Palm awarded by the Government of the United States to Dr. H. J. Gough, Prof. A. V. Hill, Sir Frank Smith and Dr. R. L. Smith-Rose, 513
Medal of Honour with Silver Palm awarded by the Government of the United States to Dr. H. Roxbee Cox, 291
Medal for Merit awarded by the Government of the United States to Dr. R. V. Jones, 513
Medical Curriculum : Recommendations as to the (General Medical Council), 481
Medical Dictionary : English–Spanish Chemical and (Morris Goldberg), *review*, 418
Medical Man : An Early Nineteenth Century American, *review* by Dr. E. Ashworth Underwood, 38
Medical Rehabilitation, 220
Medical Research : Beit Memorial Fellowships for, 152
Medical Students : Biology for (C. C. Hentschel and Dr. W. R. Ivimey Cook), fourth edition, *review* by A. S., 853
Medicine : The Application of Artificial Radioactivity to Biology and (Dr. John H. Lawrence), 51
Medicine (Experimental Biology and) : State Laboratory for, Novi Sad, Yugoslavia (Dr. Petar N. Martinovitch), 476
Medicine (Preventive) : Advances in, during the War of 1939–45 (Sir Arthur MacNalty), 631
Medicine and Man : Genetics, (H. J. Muller, C. C. Little and Laurence H. Snyder), *review* by Prof. F. A. E. Crew, 590
Mediterranean Coast of Palestine : Erythrean Fishes on the (Dr. G. Haas and H. Steinitz), 28
Mediterranean Region : Plant Cover of the, *review*, 416
Megaloblasts in Bone Marrow Cultures : Maturation of (Prof. St. Rusznyák S. Löwinger and L. Lajtha), 757
Meiosis in Bougainvillea (G. B. Wilson), 121
Melchett Medal for 1947 of the Institute of Fuel awarded to Major Kenneth Gordon, 360
Meldola Medal of the Society of Maccabæans to be awarded in 1948, 360
Men of Science (British) : American Awards to, 291, 513
Mendelian Inheritance in New Zealand Romney Sheep (Dr. F. W. Dry, A. Stewart Fraser and G. M. Wright), 646
Mentally Ill in America : The (Albert Deutsch), *review* by Dr. G. W. T. H. Fleming, 279
Mercaptoimidazole Derivatives : Reported Preparation of, by Methylation of 3 : 5-Disubstituted Thiohydantoins (Dr. R. E. Stuckey), 189
Mercurochrome as an Indicator in Acid-Alkali Titrations (Dr. J. W. Airan), 88
Mercury Tube Effect (Dr. J. O'M. Bockris and Roger Parsons), 232
Meson Decay and the Theory of Nuclear Forces (J. Leite Lopes), 866
Meson' Events ('Second) : Hypothetical Alternative Energy Sources for the (Dr. F. C. Frank), 525
Meson Theory of Nuclear Forces (Wolfgang Pauli), *review* by Prof. Max Born, 418
Mesons (Artificial) : Cross-Sections for Production of (Cécile Morette and Dr. W. H. Peng), 59
Mesons (Negative) : Decay of, in Matter (Dr. H. Fröhlich), 255
Mesons (Slow) : Observations on the Tracks of, in Photographic Emulsions (C. M. G. Lattes, Dr. G. P. S. Occhialini and Dr. C. F. Powell), 453, 486
Mesozoic Faunas of Peru, 118
Metabolism : Carbohydrate (Prof. Samuel Soskin and Dr. Rachmiel Levine), *review* by Prof. J. H. Quastel, 107
Metabolism of Synthetic Œstrogens in Man (Dr. A. E. Wilder Smith), 787
Metal (Titanium) : Smears of (Dr. W. A. Wooster and G. L. Macdonald), 260
Metallic Mirrors by Free Radicals : A New Technique for Following the Attack of (Dr. G. Whittingham), 671
Metallurgical Problems involved in the Generation of Useful Power from Atomic Energy (Sir Wallace Akers), 182
Metallurgy (Powder) : Abstracts on, 705
Metallurgy (Process) : The Physical Chemistry of (Faraday Society general discussion on), 564
Metals : Influence of Water on the Lubrication of (E. D. Tingle), 710
  Mechanical Properties of (Summer School and conference at the University of Bristol on), 696
  New, for Old (Sir Edward Appleton), 308
  The Structure and Physical Properties of (Institute of Physics, Midlands Branch and the X-Ray Analysis Group, joint conference on), 601
Metals (Plastically Deformed) : Residual Lattice Strains in (G. B. Greenough), 258
Metals and Alloys : War-Time Developments in (F. C. T.), 308
Metamorphosis in Insects : The Corpus Allatum and the Control of (Dr. V. B. Wigglesworth), 16
Metaphosphate in Yeast : Physiological Heterogeneity of (E. Juni, Prof. M. D. Kamen, S. Spiegelman and J. M. Wiame), 717
Meteor Shower : Detection by Radar of a New, 118
Meteor Trails : Electron Density in (Dr. A. C. B. Lovell), 670
Meteoric Ionization : Meteors, Comets and (Physical Society discussion on), 76
  Radio Reflexions from (Physical Society discussion on), 74
Meteors : Evaporation of (T. L. Eckersley), 91
Meteors, Comets and Meteoric Ionization (Physical Society discussion on), 76
Methionine in Urine (Edward G. Tomich), 604
Methyl-Iodine and Methyl-Magnesium : Bond-Strengths of (Prof. A. R. Ubbelohde and H. Mackle), 303
Methylation of 3 : 5-Disubstituted Thiohydantoins : Reported Preparation of Mercaptoimidazole Derivatives by (Dr. R. E. Stuckey), 189
Mice : Electron Microscope Studies of Normal and Malignant Tissues of High- and Low-Breast-Cancer Strains of (Prof. R. D. Passey, Dr. L. Dmochowski, Prof. W. T. Astbury and Dr. R. Reed), 565
Mice (Albino) : Induced Polycythæmia by *l*-Ascorbic Acid in (Jui-Ming Chen), 681
Microbes : l'Organisme en lutte contre les (André Boivin et Albert Delaunay), *review*, 735
Microbiological Assay Procedure : A Modified (A. L. Bacharach), 640
Microbiological Assays : General Equation for the Serial Dilution Technique in (A. M. Wild), 57
Microbiological Method of Standardizing Liver Extracts (Prof. S. Mahdihassan and Vasudev M. Bakshi), 404
Microbiological Oxidation of Cholesterol with *Azotobacter* (J. Horváth and A. Krámli), 639
Microbiology : Fourth International Congress for (Dr. Ralph St. John-Brooks), 596
Micro-Estimation of Sugars separated on the Filter Paper Chromatogram (J. R. Hawthorne), 714
Microflora in the Salt Pseudomorph Beds, Salt Range, Punjab : Occurrence of (A. K. Ghosh and A. Bose), 796
Microfotografia e Macrofotografia (Prof. Edgardo Baldi), *review* by Dr. H. H. Hopkins, 553

Micro-organisms : Hyper- and Avitaminosis in (Dr. M. N. Meissel), 269
Micropalaeontology : Principles of (Martin F. Glaessner), *review* by Prof. B. Sahni, 771
Micropalaeontology in Geology, *review* by Prof. B. Sahni, 771
Microscopy : A Variable Phase-Contrast System for (E. Wilfred Taylor and B. O. Payne), 338
Microscopy (Electron) : Progress in (Electron Microscopy Group of the Institute of Physics conference on), 762
Microseisms : Relations between Sea Waves and (Dr. G. E. R. Deacon), 419
Microseisms and Atmospheric Oscillations (Ernest Tillotson), 321
Migrations of Salmon in the Sea (J. W. Menzies), 33
Mild Steel : X-Ray Diffraction Studies of Yielding in (Dr. E. W. Fell), 259
Mild Steel in Strongly Alkaline Solutions : Anodic Behaviour of (Chas. D. Weir), 259
Milk : Contribution of the Major Constituents to the Refractive Index of (K. S. Rangappa), 719
Milk (Raw and Heated) : Limitations of the Colony Count Test for Assessing the Total Number of Viable Bacteria in (C. S. Morris and M. A. Edwards), 434
Milk (Whale's) : Ascorbic Acid Content of (Dr. Michael Begg), 430
Milk, Tinned Foods and Bread (Royal Sanitary Institute, Food and Nutrition Section, and the Society of Chemical Industry, Food Group, joint meeting on), 307
Million-Volt Accelerating Equipment of the Cavendish Laboratory, Cambridge : The One (Dr. W. E. Burcham), 316
'Mimicry' in Fishes (Dr. Ethelwynn Trewavas), 120, 509 ; (Prof. G. D. Hale Carpenter), 508
Mineral Balance in the Domestic Fowl : Gonadal Hormones and (Dr. R. H. Common, W. A. Rutledge and R. W. Hale), 541
Mineral Content and Growth of Plants : Effect of 4-Chloro-2-Methyl Phenoxyacetic Acid on the (A. Rhodes and Dr. W. G. Templeman), 825
Mineral Deficiencies on Tillage Land : Survey of (Dr. William Plant), 336
Mineral Industry in 1945 : The Canadian, 846
Mineral Production of Canada, 846
Mining and Metallurgy at Adelaide, 150
Mint : Newton at the (Sir John Craig), *review* by Prof. E. N. da C. Andrade, 589
Miocene Expedition : The British-Kenya (Prof. W. E. Le Gros Clark), 891
Miracle Drug, the Inner History of Penicillin (David Masters), *review* by Prof. L. P. Garrod, 38
Miracles, a Preliminary Study (C. S. Lewis), *review* by Sir John Myres, 275, 648
Mirrors (Metallic) : A New Technique for Following the Attack of, by Free Radicals (Dr. G. Whittingham), 671
Missing Factor in Science (Prof. Herbert Dingle), 108, 613 ; (Prof. J. D. Bernal), 612
Mittelmeerländer : Das Pflanzenkleid der (Prof. Dr. M. Rikli), *review*, 416
Mixtures of Sugars : Quantitative Estimation of, by the Paper Chromatogram Method (A. E. Flood, Prof. E. L. Hirst and Dr. J. K. N. Jones), 86
Models of Physical Processes : Demonstration (Dr. F. A. Ward), 151
Moisture Content of Dehydrated Stockfish : Critical (G. F. van Wyk), 872
Molecular Compounds involving Copper Diphenylacetate (Dr. Malcolm Crawford), 19
Molecular Structure of Phthiocerane : Infra-Red Spectrum and (S. Ställberg-Stenhagen and Prof. E. Stenhagen, and N. Sheppard, Dr. G. B. B. M. Sutherland and A. Walsh), 580
Molecular Vibrations : Interaction Terms in (Prof. C. A. Coulson, Dr. Jules Duchesne and C. Manneback), 793
Molecular Weight of *a*-Amylase (Carl-Erik Danielsson), 899
Molecule : The Labile (Faraday Society discussion on), 326, 778
Molecules (Chain) : Configuration and Packing of, of Native Starch in the *B*-Modification (Dr. D. Kreger), 369
Molecules (Hæmocyanin) : Shape of (Dr. A. Polson and Dr. Ralph W. G. Wyckoff), 153
Molecules (Large) : Mechanical Degradation of (William John Morris and Dr. Robert Schnurmann), 674
Molten Electrolytes : Anode Phenomena in (A. J. Rudge, W. N. Howell and H. Hill), 504
Monopoly : Inventions, Patents and (Peter Meinhardt), *review* by Sir William Jarratt, 482
Moon ? : The Magnetic Field of the (Prof. S. Chapman), 395
Morphology of *B. megatherium* Bacteriophage (T. A. McLauchlan, Elna M. Clark and F. W. Boswell), 755
Morphology of Infection by the Vole Acid-Fast Bacillus : Notes on the (Dr. A. H. T. Robb-Smith), 687
Mortality of *Aedes aegypti* Feeding on Rabbits receiving Oral 'Gammexane' (P. C. C. Garnham), 156
Mosquitoes : Marking, with Fluorescent Compounds and Watching them by Ultra-violet Light (Dr. Rajindar Pal), 298
Mosquitoes and Yellow Fever in the Sudan : Relationship of (Dr. J. Lewis), 185
Motion (Accelerated) : Relativity of (Dr. D. Meksyn), 834
Moulds : Action of 2-Aminofluorene on (Dr. Elisa Morelli and Dr. Giacomo Misler), 21
Moustached Warbler in Britain : Breeding of the (R. A. Hinde and A. S. Thom), 636
Movements : Passive, of Newly Formed Acrogenous Spores in *Verticillium* and some other Genera of the Hyphomycete Fungi (C. J. La Touche), 679
Mucin as Substrate of Enzyme Action by Viruses of the Mumps Influenza Group (Dr. F.-M. Burnet, J. F. McCrea and S. G. Anderson), 404
Mud : Insecticidal Effect of Surface Deposts of D.D.T. on (A. B. Hadaway and F. Barlow), 363
Multiple Innervation of Cutaneous Pain 'Spots' in relation to the Quality of Pain Sensibility : Significance of (Dr. G. Weddell, D. C. Sinclair and W. H. Feindel), 27
Mumps Influenza Group : Mucin as Substrate of Enzyme Action by Viruses of the (Dr. F. M. Burnet, J. F. McCrea and S. G. Anderson), 404
Murine Type of Tubercle Bacillus (the Vole Acid-Fast Bacillus), (Dr. A. Q. Wells), 687
Muscle (Isolated) : Interpretation of the Exchange of Radio-Sodium in (Dr. Hans H. Ussing), 262
Muscular Contraction : Chemistry of (A. Szent-Györgyi), *review* by Dr. Kenneth Bailey, 550
Muse : Newton Demands the, Newton's *Opticks* and the Eighteenth Century Poets (Marjorie Hope Nicolson), *review* by Prof. E. N. da C. Andrade, 517
Museums : Appeal of, *review* by T. H. Hawkins, 734
Musical Acoustics (Conference at Liège on), 765
Mutants of Diptera : White-eyed (Prof. A. H. Sturtevant), 754
Mutation of the Blow-fly (*Calliphora erythrocephala*) : A Sex-linked and Sex-limited White-eyed (Dr. P. Tate), 361
Mutations in Dried Bacteria : X-Ray Induced (Miss P. Devi, Dr. G. Pontecorvo and Dr. C. Higginbottom), 503
Mycological Periodical : A New, 292
Mycorrhiza Pigment : Corticrocin, a (Prof. Holger Erdtman), 331
Myosin : Electron Microscope Investigation of the Action of Salt Solutions on (Prof. Silvio Ranzi), 712

'NAGANA' Film available on loan from the South African Scientific Liaison Office, 706
Names into Cipher, *review* by R. Brightman, 175
Nation's Food : The (edited by A. L. Bacharach and Theodore Rendle), *review* by Dr. Leslie J. Harris, 242
National Economy : Patents and the, *review* by Sir William Jarratt, 482
National Health : Present-Day Social and Economic Aspects of (American Philosophical Society symposium on), 360
National Parks, 447
National Parks in England and Wales : Report of the Hobhouse Committee on, 809
National Parks and the Conservation of Nature in Scotland : Report of the Scottish National Parks Committee on, 809
Native Animals of New Zealand (A. W. B. Powell), *review* by T. H. Hawkins, 734
Native Starch in the *B*-Modification : Configuration and Packing of Chain Molecules of (Dr. D. Kreger), 369
Natural Frequencies of Vibration : The Prediction of, *review* by Prof. W. J. Duncan, 623
Natural History : The Possibilities of (Prof. W. A. F. Balfour-Browne), 342
  Wonders of (E. L. Grant Watson), *review*, 775
Natural Structures : Structures Produced in Clays by Electric Potentials and their relation to (Leo Casagrande), 470
Naturalist Again : Highland (Dugald Macintyre), *review* by Seton Gordon, 693
Naturalist's Notes : A, *review* by Seton Gordon, 693
Nature : International Conference for the Protection of (Dr. J. Ramsbottom), 320
Nature in England and Wales : Conservation of (Report of the Huxley Committee on), 809
Nature in Scotland : National Parks and the Conservation of (Report of the Scottish National Parks Committee on), 809
Nature Protection in Great Britain (Dr. G. F. Herbert Smith), 457
Nautical Almanac : The Navigational Work of the (D. H. Sadler), 427
Naval Vessel : Gas-Turbine Propulsion in a (Metropolitan-Vickers Electrical Co., Ltd.), 392
Navigational Work of the Nautical Almanac (D. H. Sadler), 427
Nederlandsche Baanbrekers der Wetenschap (J. C. Alders), *review* by Lieut.-Colonel Ernest Tillotson, 449
Negative Adsorption : Calculation of Surface Areas from Measurements of (Dr. R. Kenworthy Schofield), 408
Negative Mesons in Matter : Decay of (Dr. H. Fröhlich), 255
Neon Isotopes Bombarded with Protons : Gamma-Ray Yield Curves of Separated (K. J. Broström, T. Huus and J. Koch), 498
*neo*Pentyl Alcohol and Steric Hindrance (I. Dostrovsky, Prof. E. D. Hughes and Prof. C. K. Ingold), 901
Neostrychnine : Oxidation of (Dr. R. N. Chakravarti and Sir Robert Robinson), 18
Nephrectomy in the Rat (Bilateral) : Hypertension after (E. Braun-Menéndez and Prof. U. S. v. Euler), 905
Nephrotoxic and Renotropic Effects of Lead on White Rats and its Prevention by *B.A.L.* (Dr. Hugo Chiodi and Rodolfo A. Sammartino), 680
Neptune : John Couch Adams and the Discovery of (Sir Harold Spencer Jones), 324
Neptunium (239) : Radiations from Uranium (239) and (Prof. N. Feather), 749
  β- and γ-Radiation from U^{239} and (Prof. Hilding Slätis), 579
Nerve Cells (Chromatolytic) : Osmophilic Granules in (Dr. P. Glees), 194
Nervous Impulses on the Colour-dress of Hermaphrodite Teleostean Fish : Influence of Hypophyseal Hormone and of (Dr. O. Peczenik and M. Zei), 788
Nervous System : The Integrative Action of the (Sir Charles Sherrington), *review* by Prof. E. D. Adrian, 623
Netherlands, 1940–1945 : Experimental Embryology in the (Prof. M. W. Woerdeman and Prof. Chr. P. Raven), *review*, 626
Neurotic Personality : The, *review* by Dr. Clifford Allen, 887
Neutron Chain Reaction : Controlled Fast, 426
Neutrons : Evidence against Spontaneous Emission of, by Uranium X (Dr. Hl. de Vries and H. Groendijk), 435
New Zealand : Native Animals of (A. W. B. Powell), *review* by T. H. Hawkins, 734
New Zealand Romney Sheep : Mendelian Inheritance in (Dr. F. W. Dry, A. Stewart Fraser and G. M. Wright), 646
Newborn: Determination of Bilirubin in the Umbilical Blood as an aid in the Early Diagnosis of Hæmolytic Disease in the (Dr. A. Sadowski, Y. M. Bromberg and A. Brzezinski), 192
New-born Children : Response of, to Hypertonic Solutions of Sodium Chloride and of Urea (R. F. A. Dean and Prof. R. A. McCance), 904
Newfoundland : Report on Nutrition in (Dr. D. P. Cuthbertson), 135
Newfoundland-Labrador (the Eastern Part of the Labrador Peninsula) : Outlines of the Geography, Life and Customs of (Prof. V. Tanner), *review*, 735
Newton Demands the Muse, Newton's *Opticks* and the Eighteenth Century (Marjorie Hope Nicolson), *review* by Prof. E. N. da C. Andrade, 517
Nickel-Thoria-Kieselguhr Catalyst for Fischer-Tropsch Synthesis : X-Ray Diffraction Studies of a (Dr. K. M. Chakravarty and Ranjit Sen), 907
Nicotinamide in Mammals : Tryptophane as Precursor of (Dr. P. Ellinger and M. M. Abdel Kader), 675

Nigeria : Botanical Expedition to, 785
Nightmare : Noah's, *review* by G. H. S. Bushnell, 852
Nigrosine Method for Chromosome Counts applicable to Growing Plant Tissues : A Rapid (Dr. Gösta von Rosen), 121
Nile Basin : The, Vol. 7, The Future Conservation of the Nile (Dr. H. E. Hurst, R. P. Black and Y. M. Simaika), 215
  A Long-Term Plan for the (Dr. C. E. P. Brooks), 215 ; (Dr. H. E. Hurst, R. P. Black and Y. M. Simaika), 611
Nineteenth Century American Medical Man : An Early, *review* by Dr. E. Ashworth Underwood, 38
Nitrates (Organic) : Thermal Decomposition of (L. Phillips), 753
Nitrogen : Elementary Isotopic Analysis—Determination of (A. D. Hirshenbaum, S. G. Hindin and A. V. Grosse), 187
Nitrous Acid with Chlorophyll : Reaction of (M. L. Sapiro), 796
Noah's Nightmare, *review* by G. H. S. Bushnell, 852
Nobel Prize for Chemistry for 1947 awarded to Sir Robert Robinson, 703
Nobel Prize for Physics for 1947 awarded to Sir Edward Appleton, 703
Nobel Prize for Physiology and Medicine for 1947 awarded to Prof. Bernardo A. Houssay and Prof. Carl F. and Mrs. Cori, 599
Nomadacris septemfasciata in Africa, 1927–1945 : Migrations and Breeding of the Red Locust (V. Morant), 67
Nomenclature : Elemental (Prof. Charles H. Blake), 648
Nomogram for the Tetrachoric Correlation Coefficient (Max Hamilton), 473
Non-Cancerous Lipoids (Cancerous and) : Fluorescence of (H. S. Penn and Prof. Joseph Kaplan), 18
Non-measurable : The Measurable and the (Dr. A. Vibert Douglas), 908 ; (Prof. Herbert Dingle), 908
Non-Newtonian Fluids : Hydrodynamics of (R. S. Rivlin), 611
Non-Specific Resistance Factor in the Albumin Residue revealed by the Serial Cephalin Flocculation Curve (Dr. Jack G. Makari), 201
Norges fjellbeiter : Sikilsdalen og (Prof. Rolf Nordhagen), *review* by Prof. I. Manton, 4
Norman Times : Sussex and Normandy in (J. E. Ray), 343
Normandy in Norman Times : Sussex and (J. E. Ray), 343
North America : The Arboretums and Botanical Gardens of (Dr. Donald Wyman), *review*, 775
  The Grasshopper Problem in (Dr. B. P. Uvarov), 857
  Low-Temperature Physics in (Prof. J. F. Allen), 736
North-South and East-West Rooms : Radiant Temperatures of Walls in (J. Neumann), 472
Northern Ireland : Agriculture in, 862
Norway : Ecology of, *review* by Prof. I. Manton, 4
Notation and Enumeration System for Organic Compounds : A New (Dr. G. Malcolm Dyson), *review* by R. Brightman, 175
Nuclear Age : From Galileo to the (Prof. Harvey Brace Lemon), *review* by Lieut.-Colonel H. D. Anthony, 210
Nuclear Explosion Recorded by Photographic Emulsion Method (Dr. R. R. Roy), 498
Nuclear Fission : Peaceful Applications of (British Association, Section A (Mathematics and Physics), symposium on), 451
Nuclear Forces : Meson Decay and the Theory of (J. Leite Lopes), 866
  Meson Theory of (Wolfgang Pauli), *review* by Prof. Max Born, 418
Nuclear Forces and the Magnetic Moment of the Deuteron (Prof. H. S. W. Massey and Tsi-Ming Hu), 794
Nuclear Magnetic Relaxation (N. Bloembergen, E. M. Purcell and R. V. Pound), 475
Nuclear Magnetic Resonance at Low Temperatures (B. V. Rollin, J. Hatton, A. H. Cooke and R. J. Benzie), 436
Nuclear Physics : (Atomic Energy Research Establishment conference on), 492
Nuclear Quadrupole Moments : Definition of (E. H. Rhoderick), 255
Nuclear Reactions : New, 897
Nuclear Transformations in the New High Energy Ranges (Prof. Glenn T. Seaborg), 897
Nucleation during Recrystallation of Aluminium : Growth of 'Stimulated Crystals' and Rate of (Prof. W. G. Burgers), 398
Nuclei : Excitation of, by Electrons (Dr. Bruno Touschek), 500
Nuclei (Heavy) : 'Evaporation' of (D. H. Perkins), 299
Nucleic Acid (Society for Experimental Biology, Symposia No. 1), *review* by N. W. Pirie, 852
Numbers : A Chapter in the Theory of (Prof. L. J. Mordell), *review* by H. T. H. P., 315
Nutrition : Animal (Prof. Leonard A. Maynard), second edition, *review* by Dr. D. P. Cuthbertson, 854
Nutrition in Newfoundland : Report on (Dr. D. P. Cuthbertson), 135
Nutrition and Symbiosis (Dr. E. C. Owen), 78
Nutritional Requirements of the Larva of *Aedes aegypti* L. : Further Observations on the (Dr. L. Golberg and Dr. B. De Meillon), 582
Nylon : Effect of Polar Vapours on the Direct-Current Conductance of Keratin and (G. King and J. A. Medley), 438

OBSERVATIONS Underground of Penetrating Cosmic Ray Showers (Dr. E. P. George and A. C. Jason), 327
Oceanic Birds, a Pictorial Survey, *review* by R. M. Lockley, 591
'Octa-Benzene', Cyclo-octatetraene (C_8H_8), (O. Bastiansen, Prof. O. Hassel and Prof. A. Langseth), 128
Oddities : Some Human (E. J. Dingwall), *review*, 39
Œstrogenic Hormones : Nature of the C/D-Ring Union in the (Dr. C. W. Shoppee), 64
Œstrogens in Man : Metabolism of Synthetic (Dr. A. E. Wilder Smith), 787
Oil : A Terpene-type Essential, from a Fern (*Paesia scaberula*), (Dr. Lindsay H. Briggs and Maurice D. Sutherland), 333
Olefines : Co-ordination Complexes containing (Prof. A. E. A. Werner), 644
Olefins : Co-ordinate Bond Formation by (L. Bateman), 56
  Oxidation of, by Chromic Acid (A. Byers and Dr. W. J. Hickinbottom), 402
  Polymerization of, by Friedel-Crafts Catalysts (Dr. A. G. Evans, G. W. Meadows and Prof. M. Polanyi), 869
Oliarius : Symbiosis in (Prof. P. Buchner), 264
Onslaught on a Superstition, *review* by Joshua C. Gregory, 276
Operational Research in War and Peace (British Association, Division of the Social and International Relations of Science, discussion on), 660
Operator's Response in Manual Control : The Nature of the (Prof. A. Tustin), 341
Optical Image Formation : Diffraction and (Prof. F. Zernicke), 394
Optical Isomers of Amidone, with a Note on *iso*Amidone (R. H. Thorp, E. Walton and P. Ofner), 605
Optical Rotatory Power and Atomic Dimension (Dr. W. Gerrard and W. Lessing), 467
Optical Systems for Television : Plastic (Dr. D. Starkie), 99
Optical Transitions (Forbidden) : Decay of Luminescence due to (G. F. J. Garlick and A. F. Gibson), 303
Optics : X-Ray (Dr. W. Ehrenberg), 330
Orchids of Kent and Sussex : Some (E. J. Bedford), 343
Organic Acids on a Paper Sheet Support : Partition Chromatography of (J. W. H. Lugg and B. T. Overell), 87
Organic Bases (Strong and Weak) : Uptake of Water by Collagen in Solutions of Alkalis and (Dr. J. H. Bowes and R. H. Kenten), 827
Organic Compounds : A New Notation and Enumeration System for (Dr. G. Malcolm Dyson), *review* by R. Brightman, 175
Organic Nitrates : Thermal Decomposition of (L. Phillips), 753
Organisation of the Cell Walls of Tracheids and Wood Fibres (A. B. Wardrop and Dr. R. D. Preston), 911
Organisation of Industrial Research (Dr. R. P. Russell), 547
Organisation for Scientific and Industrial Research, 883
l'Organisme en lutte contre les microbes (André Boivin et Albert Delaunay), *review*, 735
Origin of Terrestrial Magnetism : Frenkel' Views on the (Prof. Louis B. Slichter and Dr. E. C. Bullard), 157
Orobanche minor : Flowering Responses in a Strain of (M. Holdsworth and P. S. Nutman), 223
Oscillations : Plasma-Electron (Dr. E. B. Armstrong), 713
Oscillations of Elementary Magnets (Prof. V. Arkadiew), 397
Osmophilic Granules in Chromatolytic Nerve Cells (Dr. P. Glees), 194
Outdoor Air : Sublimation in (Dr. B. M. Cwilong), 198
Ova of *Pila* : Lipochromes in the (Dr. Alex Comfort), 333
Over-estimation of Probable Errors (R. T. Leslie), 751
Over-population as a World Problem (Sir John Megaw), 783
Over-summering and Over-wintering of the Cereal Rust Fungi (Dr. P. D. Critopoulos), 507
Oviparity in *Littorina saxatilis* (Olivi), (G. Seshappa), 335
Ox Spleen : β-Glucuronidase Activity of (Dr. G. T. Mills), 638
Oxford : The Geology of (Dr. W. J. Arkell), *review* by Prof. H. L. Hawkins, 243
Oxidation : Microbiological, of Cholesterol with *Azotobacter* (J. Horváth and A. Krámli), 639
Oxidation of Gaseous Formaldehyde : Mechanism of the (D. W. E. Axford and Prof. R. G. W. Norrish), 537
Oxidation of Insulin by Performic Acid (Dr. F. Sanger), 295
Oxidation of Neostrychnine (Dr. R. N. Chakravarti and Sir Robert Robinson), 18
Oxidation of Olefins by Chromic Acid (A. Byers and Dr. W. J. Hickinbottom), 402
Oxidation Product of 4 : 4-Diethoxydinaphthyl : A Semi-Quinonoid (G. Baddeley, P. Graddon and Prof. J. Kenner), 187
Oxidation and Reduction : Activation of Copper by (F. C. Aldred and Dr. F. Happey), 267
Oxide-Coated Cathodes : Thermionic Emission from (Electronics Group of the Institute of Physics summer meeting on), 725
Oxidized Insulin : Adsorption Analysis of (Prof. A. Tiselius and F. Sanger), 433
Oxygen : Effect of, on the Frequency of the Chromosome Aberrations produced by X-Rays (Dr. J. M. Thoday and John Read), 608
Oxygen Bridging—a New Type of Ionic Equilibrium: Hydrolysis of B^{3+}. (Fredrik Granér and Dr. Lars Gunnar Sillén), 715

PACKING of Chain Molecules of Native Starch in the B-Modification : Configuration and (Dr. D. Kreger), 369
Pæonia (Genus) : A Study of the (F. C. Stern), *review* by Dr. George Taylor, 551
Paesia scaberula : A Terpene-type Essential Oil from a Fern (Dr. Lindsay H. Briggs and Maurice D. Sutherland), 333
Pagham Harbour : Some Interesting Birds of (S. J. Teideman), 343
Pain Sensibility : Significance of Multiple Innervation of Cutaneous Pain 'Spots' in relation to the Quality of (Dr. G. Weddell, D. C. Sinclair and W. H. Feindel), 27
Pakistan : The Profession of Chemistry in India and, 743
Palæobotany for Everyman, *review* by Prof. John Walton, 734
Palestine : Erythrean Fishes on the Mediterranean Coast of (Dr. G. Haas and H. Steinitz), 28
Palladium Tube Technique in the Study of the Role of Hydrogen in Combustion Systems : Use of a (J. R. Arthur and E. Sterling), 869
Paludrine : Benziminazoles related to (R. M. Acheson, Dr. F. E. King and P. C. Spensley), 53
  Mode of Action of (Dr. P. B. Marshall), 463
Panda : The Giant, 635
Paper for Technical Journals (H. Wilson), 636
Paper Chromatogram Method : Quantitative Estimation of Mixtures of Sugars by the (A. E. Flood, Prof. E. L. Hirst and Dr. J. K. N. Jones), 86
Paper-Making : Modern (Robert Henderson Clapperton and William Henderson), third edition, *review* by Dr. Julius Grant, 814
Paper Sheet Support : Partition Chromatography of Organic Acids on a (J. W. H. Lugg and B. T. Overell), 87
Para-Bromochlorobenzene : Crystal Structure of (A. Klug), 570
para-Dinitrobenzene and *para*-Nitraniline : Crystal Structures of (S. C. Abrahams and Prof. J. Monteath Robertson), 569
para-Nitraniline : Crystal Structures of *para*-Dinitrobenzene (S. C. Abrahams and Prof. J. Monteath Robertson), 569
Paramagnetic Resonance and Magnetic Energy Levels in Chrome Alum (D. M. S. Bagguley and Dr. J. H. E. Griffiths), 532
Parenchyma Cells in Dicotyledonous Woods : Initial (K. A. Chowdhury), 609
Paris : Rutherford Celebrations in (Prof. M. L. Oliphant), 806
Parks : National, 447
Parks in England and Wales : National (Report of the Hobhouse Committee on), 809

Parks and the Conservation of Nature in Scotland : National (Report of the Scottish National Parks Committee on), 809
Parliament : Audibility of Members of, 185
Particles : Elementary, and the Geomagnetic Field (Prof. T. G. Cowling), 847 ; (Dr. J. Barnóthy), 847
β-Particles in Alcohol Vapour and Argon : Primary Ionization of (Dr. S. C. Curran and J. M. Reid), 866
Particles (New Unstable Elementary) : Evidence for the Existence of (Dr. G. D. Rochester and Dr. C. C. Butler), 855
Partition Chromatography : Detection of the Free Amino-Acids of Plant Cells by (Dr. C. E. Dent, W. Stepka and Prof. F. C. Steward), 682
  Identification of Creatine by (G. A. Maw), 261
Partition Chromatography (Filter Paper) : Application of, to Radioactive Tracer Studies (Dr. R. M. Fink, Dr. C. E. Dent and K. Fink), 801
Partition Chromatography of Organic Acids on a Paper Sheet Support (J. W. H. Lugg and B. T. Overell), 87
Passive Movements of Newly Formed Acrogenous Spores in *Verticillium* and some other Genera of the Hyphomycete Fungi (C. J. La Touche), 679
Patella coerula L. and *Diodora gibberula* (Lam.) : Sex Reversal in (G. Bacci), 94
Patents and Monopoly : Inventions, (Peter Meinhardt), *review* by Sir William, Jarratt, 482
Pathology of Glasshouse Crops, 915
Peace : Geography in War and (Prof. E. G. R. Taylor), 285
  Operational Research in War and (British Association, Division of the Social and International Relations of Science, discussion on), 660
  Central Planning in War and (Sir Oliver Franks), 1
  Science and, *review* by R. Brightman, 733
  Science in War and (Sir Henry Dale), 280
  Science, Liberty and (Aldous Huxley), 172 ; *review* by R. Brightman, 733
  Zoologists in War and (Dr. Edward Hindle), 285
Peaceful Applications of Nuclear Fission (British Association, Section A (Mathematics and Physics), symposium on), 451
Peach Orchards in England (Justin Brooke), *review*, 814
Pearls of *Tridacna squamosa* Lam. and *Hippopus hippopus* (Linn.) : On the Structure of the Shells and (Dr. A. Reyne), 653
Pedler Lecture of the Chemical Society (Sir Ian Heilbron), 706
Pegmatites from Manitoba : Geological Age—the Extreme Antiquity of (Dr. L. H. Ahrens), 874
Pellets (Filter Paper) : Use of, in the Spectrochemical Analysis of Solutions (Prof. N. S. Bayliss and D. J. David), 334
Penetrating Cosmic Ray Showers : Observations Underground of (Dr. E. P. George and A. C. Jason), 327
Penetration of Magnetic Field into Superconductors (E. Laurmann and Dr. D. Shoenberg), 747
Penicillic Acid : Synthesis of the Antibiotic (R. A. Raphael), 261
Penicillin : Miracle Drug, the Inner History of (David Masters), *review* by Prof. L. P. Garrod, 38
Penicillin at the University of Oxford : Chemistry of (Sir Robert Robinson), 745
Penicillin and other Antibiotics (British Association, Sections B (Chemistry), I (Physiology) and K (Botany), symposium on), 554
Penicillin Resistance and Assimilation Affinity in *Staphylococcus aureus* : Correlation between (Dr. Ernest F. Gale), 407
Penicillin-Salt Solutions with Sodium Citrate : Stabilization of (Dr. L. Hahn), 639
Penicillinase : Biochemistry of *Escherichia coli* and the Production of (Dr. Luigi Corini and Annamaria Torriani), 332, *errata*, 394
Penicillium : Production of Citrinin by Five Species of (Dr. A. V. Pollock), 331
Penicillium nigricans-janczewskii Series : A Fungistatic and Bacteriostatic Red Pigment produced by a Strain of the (P. J. Curtis and J. F. Grove), 574
Peonies, *review* by Dr. George Taylor, 551
Peoples of the Indian Archipelago, *review* by Prof. J. H. Hutton, 732
Peoples of Malaysia (Fay-Cooper Cole), *review* by Prof. J. H. Hutton, 732
Per-Acids on the Iso-Octenes : Action of the (Dr. J. G. M. Bremner), 575 ; (Dr. W. J. Hickinbottom), 576
Perception of Fine Detail : The Visual (Prof. H. Hartridge), 880
Performic Acid : Oxidation of Insulin by (Dr. F. Sanger), 295
Perivascular Spaces of the Brain : Phylogenesis of the (L. Bakay, Jun.), 789
Permeability of Ferromagnetic Materials : High-Frequency (G. Eichholz and G. F. Hodsman), 302
Personality : Dimensions of (Dr. H. J. Eysenck), *review* by Dr. Clifford Allen, 887
Peru : Mesozoic Faunas of, 118
Pests of Stored Foods (Food and Agriculture Organisation of the United Nations conference on), 51, 739
Petroleum Geology in Germany (Dr. W. Rühl), 724
Pflanzenkleid der Mittelmeerländer : Das (Prof. Dr. M. Rikli), *review*, 416
*p*H and Temperature : Optimum, and Energy of Activation of the Transamination between Glutamic Acid and Pyruvic Acid (S. D[illegible]rling), 838
Pharmacognosy : Textbook of (Dr. T. E. Wallis), *review* by Dr. W. O. Howarth, 4
Pharmacology and Therapeutics (Prof. Arthur R. Cushny), thirteenth edition, thoroughly revised by Prof. Arthur Grollman and Dr. Donald Slaughter, *review* by Prof. J. H. Gaddum, 887
Pharmacopœia of the United States of America (the United States Pharmacopœia), thirteenth revision, *review* by Prof. J. H. Gaddum, 449
Phase-Contrast System for Microscopy : A Variable (E. Wilfred Taylor and B. O. Payne), 338
Phenazine Synthesis (Prof. G. R. Clemo and A. F. Daglish), 752
Phenazines and Benzcinnolines (Mrs. P. Z. Slack and R. Slack), 437, *erratum*, 497
Philosophic Addresses, 1700–1900 : American (Edited by Joseph L. Blau), *review* by Prof. A. D. Ritchie, 37
Philosophy : Essays in Science and (Alfred North Whitehead), *review* by Sir Edmund Whittaker, 415
  Soviet (Dr. John Somerville), *review* by Lord Lindsay of Birker, 36
Philosophy (American) : A History of (Herbert W. Schneider), *review* by Prof. A. D. Ritchie, 37
Phosphate : Urinary Excretion of, with $^{32}_{15}\text{P}$ as Indicator (Dr. J. Govaerts), 53
Phosphate in Enzymatic Syntheses : Aspects of the Biological Function of (Dr. Herman M. Kalckar), 143
Phospholipids in the Fœtus : Synthesis of (G. Popják), 841
Phospholipids in the Liver : Influence of Choline and Ethanolamine on the Rate of Formation of (Dr. A. P. Platt and R. R. Porter), 905
Phosphorescence : Fluorescence et (Prof. Maurice Curie), *review* by Prof. J. T. Randall, 483
$^{32}_{15}\text{P}$ as Indicator : Urinary Excretion of Phosphate with (Dr. J. Govaerts), 53
Photoconductive Layers : Occurrence of Random Photovoltaic Barriers in (L. Sosnowski, B. W. Soole and J. Starkiewicz), 471
Photo-Disintegration of the Deuteron (W. M. Gibson, L. L. Green and D. L. Livesey), 534
Photoelectric Cells (Dr. A. Sommer), *review* by Dr. L. E. C. Hughes, 854
Photo-electric Fourier Transformer and its Application to Sound-Films (Dr. D. Brown and J. W. Lyttleton), 709
Photogrammetry : Manual of (edited by P. G. McCurdy, L. A. Woodward, J. L. Davidson, R. M. Wilson and R. E. Ask), *review* by Prof. C. A. Hart, 659
Photographic Emulsion : Adsorption Isotherm of a, for Uranyl and Lead Ions (Dr. E. Broda), 231
Photographic Emulsion Method : Nuclear Explosion Recorded by (Dr. R. R. Roy), 498
Photographic Emulsions : Observations on the Tracks of Slow Mesons in (C. M. G. Lattes, Dr. G. P. S. Occhialini and Dr. C. F. Powell), 453, 486
Photography : Technique of X-Ray Powder (H. P. Rooksby), 7
Photoperiods in *Sesamum orientale* L. : Leaf Heteromorphism and (Prof. J. C. Sen Gupta and Santosh Kumar Payne), 510
Photostat Copies of German Scientific and Technical Papers, 427
Photovoltaic Barriers (Random) : Occurrence of, in Photoconductive Layers (L. Sosnowski, B. W. Soole and J. Starkiewicz), 471
Phthiocerane : Infra-Red Spectrum and Molecular Structure of (S. Ställberg-Stenhagen and Prof. E. Stenhagen, and N. Sheppard, Dr. G. B. B. M. Sutherland and A. Walsh), 580
Phyllotaxis (Fern) : Tensile Stress as a Factor in (Prof. C. W. Wardlaw), 678
Phylogenesis of the Perivascular Spaces of the Brain (L. Bakay, Jun.), 789
Physical Chemistry : Summer School in (University of Cambridge Department of Physical Chemistry), 292
Physical Chemistry at Durham, 291
Physical Chemistry in Great Britain : The Work of the Royal Institution in (Prof. E. K. Rideal), 245
Physical Chemistry of Process Metallurgy (Faraday Society general discussion on), 564
Physical Methods of Gas Analysis (Society of Public Analysts and other Analytical Chemists, Physical Methods Group, discussion on), 441
Physical Principles of Wave Guide Transmission and Antenna Systems (Prof. W. H. Watson), *review* by Dr. R. L. Smith-Rose, 206
Physical Processes : Demonstration Models of (Dr. F. A. Ward), 151
Physical Properties of Metals : The Structure and (Institute of Physics, Midlands Branch and the X-Ray Analysis Group, joint conference on), 601
Physical Science in Art and Industry (Dr. E. G. Richardson), second edition, *review* by F. Ian G. Rawlins, 315
Physical Theory : Fundamental (Conference at Birmingham), 627
Physicists : Applied Mathematics for Engineers and (Dr. Louis A. Pipes), *review* by E. N. Fox, 552
Physico-Chemical aspects of Chemical Carcinogenesis (William Anderson), 892
Physics : Atomic (G.-B. Instructional, Ltd., film on), 822
  Low Temperature (American Physical Society symposium on), 530
  Mathematics or, *review* by Prof. L. Rosenhead, 886
  Nuclear (Atomic Energy Research Establishment conference on), 492
  Publication of Papers on, 636
  The Union of Mathematics and, *review*, 139
Physics (Mathematical) : Methods of (Dr. Harold Jeffreys and Dr. Bertha Swirles Jeffreys), *review*, 139
Physics (Modern) : An Introduction to, *review* by Lieut.-Colonel H. D. Anthony, 210
Physics of Electric Contacts, *review* by Prof. F. Llewellyn Jones, 417
Physics in North America : Low-Temperature (Prof. J. F. Allen), 736
Physics and the Steel Industry, 684
Physics of Surface Phenomena (American Physical Society symposium on), 530
Physiological Activator of the Reticulo-Endothelial System : Histamine as a (Dr. Miklós Jancsó), 227
Physiological Congress : Seventeenth International, 248
Physiological Effects of Alkyl Polyphosphates (A. S. V. Burgen and C. A. Keele ; Mary Chennells, J. del Castillo, W. F. Floyd, D. Slome and Prof. Samson Wright), 760
Physiological Heterogeneity of Metaphosphate in Yeast (E. Juni, Prof. M. D. Kamen, S. Spiegelman and J. M. Wiame), 717
Physiology : Wider Applications of Teaching of (Prof. Winifred Cullis), 287
Physiology at Charing Cross Hospital Medical School, 561
Physiology and the Community, 345
Physiology at St. Bartholomew's Hospital Medical College, 599
Physiology at St. Thomas's Hospital Medical School, 704
Physiology at University College, Dundee, 291
Pictures : Cleaned, at the National Gallery (Dr. H. J. Plenderleith), 523
Piezo-Electricity (Prof. Walter Guyton Cady), *review* by Dr. P. Vigoureux, 348
Pigmentation of Trout : Carotenoid (D. M. Steven), 540
Pila : Lipochromes in the Ova of (Dr. Alex Comfort), 333
Pine Roots (Isolated) : Influence of the Sugar Concentration on the Growth of (V. Slankis), 645
Piston Core-Sampler (Dr. B. Kullenberg), 410
Pitfall in Correlation Theory : A (Miss S. P. Vaswani), 405
Pituitary : A New Blood-Pressure Principle of the Anterior Lobe of the (Dr. Hans Hase), 787
Pituitary Extract and Hypophysectomy (Anterior) : Effects of, on Blood-Sugar Levels after Injection of Alloxan (Mervyn Griffiths), 758

Planning : Central, in War and Peace (Sir Oliver Franks), 1
  Centralized, and the Human Factor, 1
Plant Breeders' Conference at Cambridge, 423
Plant Cells : Detection of the Free Amino-Acids of, by Partition Chromatography (Dr. C. E. Dent, W. Stepka and Prof. F. C. Steward), 682
Plant Cover of the Mediterranean Region, *review*, 416
Plant Form : The History of (Dr. H. Hamshaw Thomas), 288
Plant Physiology : Role of Trace Elements in (International Union of Biological Sciences symposium on), 564
Plant Respiration : Malonate and (Prof. J. S. Turner and V. Hanly), 296, *erratum*, 530
Plant Tissues (Growing) : A Rapid Nigrosine Method for Chromosome Counts applicable to (Dr. Gösta von Rosen), 121
Plant Tumours and Animal Cancer (R. S. de Ropp), 780
Plantes et la vie : Les (Prof. Florian Cosandey), *review*, 814
Plants : Effect of 4-Chloro-2-Methyl Phenoxyacetic Acid on the Mineral Content and Growth of (A. Rhodes and Dr. W. G. Templeman), 825
  Selective Toxic Action of Thiosulphate on (Dr. L. J. Audus and Prof. J. H. Quastel), 263
  Ancient, and the World they Lived in (Assoc. Prof. Henry N. Andrews, Jr.), *review* by Prof. John Walton, 734
Plants (Aquatic) : Diffusion of Dissolved Substances through Thalli and Leaves of (Prof. E. Steemann Nielsen), 376
Plants (Vascular) : New Divisions of (Dr. I. V. Newman), 836
Plants Duplex for the Short-style Gene : Spontaneous Occurrence in *Lythrum salicaria* of (Prof. R. A. Fisher and V. C. Martin), 541
Plasma-Electron Oscillations (Dr. E. B. Armstrong), 713
Plasmodium gallinaceum : Acquired Resistance (Twofold) to Quinine in (Dr. A. Th. Knoppers), 606
Plasmodium gallinaceum in Tissue Cultures of Embryonic Chicken Brain : Cultivation of the Erythrocytic Form of (Herta Meyer), 155
Plastic Optical Systems for Television (Dr. D. Starkie), 99
Plastically Deformed Metals : Residual Lattice Strains in (G. B. Greenough), 258
Plesianthropus : Further Remains of the Sterkfontein Ape-man (Dr. R. Broom and J. T. Robinson), 430
Plots (Small-size) : Use of, in Yield Surveys (Dr. P. V. Sukhatme), 542
Ploughshares : Swords into, 273
'Plutonium' : Naming the Elements—a Former Suggested Use of (Dr. K. R. Webb), 164
Poets' View of Newton, *review* by Prof. E. N. da C. Andrade, 517
Points on a Lattice : Random Association of (P. V. Krishna Iyer), 714
Poland : Science in (Prof. Adam Malicki), 219
Polar Auroras : Interpretation of Radio Echoes from (N. Herlofson), 867
Polar Vapours on the Direct-Current Conductance of Keratin and Nylon : Effect of (G. King and J. A. Medley), 438
Polarized Infra-Red Radiation : Absorption Spectra with (J. Mann and Dr. H. W. Thompson), 17
Polarized Infra-Red Radiation as an Aid to Crystal Analysis (D. A. Crooks), 17
Polarized Light : Starch Hydrolysis by (Dr. Elizabeth S. Semmens), 669
Polarized Radiation in Infra-Red Analysis : Use of (Dr. G. B. B. M. Sutherland and A. Vallance Jones), 567
Police Court and the Community (Miss J. E. R. Kennedy), 803
Poliomyelitis : Hydrocyanic Acid and (R. R. Scobey), 359
Pollution by Trade Wastes from Food Industries (Dr. B. A. Southgate and Dr. S. H. Jenkins), 200
Polycythæmia : Induced, by *l*-Ascorbic Acid in Albino Mice (Jui-Ming Chen), 681
Polymerization : Friedel-Crafts Catalysts in—Kinetic Measurements and the Role of Water (Prof. R. G. W. Norrish and K. E. Russell), 543
Polymerization of Isobutene by Titanium Chloride : Low-Temperature (Dr. P. H. Plesch), 868
Polymerization of Olefins by Friedel-Crafts Catalysts (Dr. A. G. Evans, G. W. Meadows and Prof. M. Polanyi), 869
Polymers : Butalastic (Frederick Marchionna), *review* by Prof. H. W. Melville, 851
Polyolefins (Cyclic Conjugated) : Synthesis of (D. H. S. Horn, J. R. Nunn and Dr. W. S. Rapson), 829
Population : International Congress on the Family and on, 183
  Number of S-Alleles in a (A. J. Bateman), 337
Population of the Soviet Union (Frank Lorimer), *review* by Prof. H. J. Fleure, 888
'Positex' : The Compounding, Pigmenting and Thickening of (Dr. C. M. Blow), 50
Position Control : Elements of (Prof. K. A. Hayes), 340
Positrons produced by a 20-MeV. Betatron : Some Experiments with Fast Electrons and (W. Bosley, Dr. J. D. Craggs and W. F. Nash), 790
Post-Primary Education : Science in (Association of Women Science Teachers Report, Part 3), 783
Potassium in Composts and Sewage Sludges : Estimate of (P. Garrick), 434
K$_2$ and NaK : Absorption Bands of Li$_2$, Na$_2$, (Dr. R. W. B. Pearse and S. P. Sinha), 159
Potassium Hydrogen Fluoride : Nature of the Hydrogen Bond in (D. Polder), 870
Potassium Ion : Antagonism between Curare and the (J. P. Quilliam and Dr. D. B. Taylor), 603
Potassium Permanganate in the Presence of Glass : Reduction of (C. B. Taylor), 56
Potato : Classification, Breeding and Preservation of the (Association of Applied Biologists symposium on), 843
Powder Metallurgy : Abstracts on, 705
Powder Photography : Technique of X-Ray (H. P. Rooksby), 7
Power from Atomic Energy : Metallurgical Problems involved in the Generation of Useful (Sir Wallace Akers), 182
Power Exhibition : Home and Factory (Science Museum), 600
Pre-capillaries and Capillaries (Retinal) : Cushion Cells in (Prof. Arnold Loewenstein), 229
Precipitation of Serum Proteins : Fractional (Dr. Tage Astrup and Aksel Birch-Andersen), 637
Precursor of Nicotinamide in Mammals : Tryptophane as (Dr. P. Ellinger and M. M. Abdel Kader), 675
Prediction of Natural Frequencies of Vibration, *review* by Prof. W. J. Duncan, 623
Pregnancy : Composition and Structure of the Liver Cell in (Dr. H. W. Kosterlitz and Rosa M. Campbell), 676
Prehistory : The Loom of (A. J. H. Goodwin), 393
Preparation and Properties of 3-Ethyl-5 : 5-dimethyloxazolidine-2 : 4-dione (W. H. Hook), 610
Preparations Rich in Cholesterol : Carcinogenic Activity of (Dr. I. Hieger), 270
Preparative Electrophoresis : An Apparatus for (Dr. J. A. V. Butler and Miss J. M. L. Stephen), 469
Present-Day Social and Economic Aspects of National Health (American Philosophical Society symposium on), 360
Press : A Free and Responsible (Commission on Freedom of the Press), 312, 413
  Freedom of the, 413
Press the Public Wants : The (Kingsley Martin), 413
Pressure : Radiation (Dr. Alexander R. Stokes), 532
Preventive Medicine during the War of 1939–45 : Advances in (Sir Arthur MacNalty), 631
Principles of Bridges (Strip Slide No. 47/1), 393
Prix Arnold Reymond : Offered by the University of Lausanne, 745
Probabilities of Magnetization (G. C. Richer), 256
Probable Errors : Over-estimation of (R. T. Leslie), 751
Process of Puberty : The, *review* by Prof. S. Zuckerman, 591
Process Control : Theoretical Foundations of (G. H. Farrington), 340
Process Metallurgy : The Physical Chemistry of (Faraday Society general discussion on), 564
Production of Artificial Mesons : Cross-Sections for (Cécile Morette and Dr. W. H. Peng), 59
Production of Citrinin by Five Species of *Penicillium* (Dr. A. V. Pollock), 331
Production of Penicillinase : Biochemistry of *Escherichia coli* and the (Dr. Luigi Gorini and Annamaria Torriani), 332, *errata*, 394
Productivity (Industrial) : Committee on, 896
Professional Electrical Engineers : The Practical Training of (Institution of Electrical Engineers), 585
Propagation of Light : Radiation Damping Theory and the (B. Ferretti and Prof. R. E. Peierls), 531
Properties of 3-Ethyl-5 : 5-dimethyloxazolidine-2 : 4-dione : Preparation and (W. H. Hook), 610
Properties of the Fibrinokinase-Fibrinolysin System (Per M. Permin), 571
Properties of Liquid Explosives (R. G. Vines), 400
Protection of Nature : International Conference for the (Dr. J. Ramsbottom), 320
Protective Coloration in Insects, and its Interpretation (Prof. G. D. Hale Carpenter), 343
Protein and Calcium : British Needs and Resources of Calories, (Nutrition Society conference on), 700
Protein-Precipitating Agents : Purification of Renin by means of (Dr. Tage Astrup and Aksel Birch-Andersen), 570
Proteins : An Improved Biuret Reaction of, and the Two-Standard Colorimetry (Dr. A. Sols), 89
Proteins (Serum) : Fractional Precipitation of (Dr. Tage Astrup and Aksel Birch-Andersen), 637
Protons : Gamma-Ray Yield Curves of Separated Neon Isotopes Bombarded with (K. J. Broström, T. Huus and J. Koch), 498
  A Radio-Frequency Ion Source with High Percentage Yield of (J. G. Rutherglen and J. F. I. Cole), 545
Protostele from a Dictyostele in *Dryopteris aristata* : Experimental Production of a (Prof. C. W. Wardlaw), 539
Psammechinus miliaris : Respiration and Cell-Division in Eggs of the Sea Urchin (Dr. Erik Zeuthen), 577
Psycho-Analysis and its Derivatives (Dr. H. Crichton-Miller), second edition, *review*, 142
Psycho-Hygiene : Social (Dr. St. Zurukzoglu), 803
Psychology of Social Change (Prof. Donald C. Marquis), 622
Psychrometric Observations in the Lower Atmosphere (Richard A. Craig), 546
Pteroylglutamic Acid in Liver Extracts and Urine (Dr. L. Golberg, Dr. B. De Meillon and J. F. Murray), 22
Puberty : The Process of, *review* by Prof. S. Zuckerman, 591
Public Expenditure : Scientific Research and, 849
Public Health Nurse and the Family Unit (Miss M. M. West), 803
Public Wants : The Press the (Kingsley Martin), 413
Public Welfare Medal for 1947 of the Marcellus Hartley Fund of the U.S. National Academy of Sciences awarded to Dr. Karl T. Compton, 169
Publication and Classification of Scientific Knowledge (Association of Scientific Workers, Cambridge Senior Branch, conference on), 496, 649
Pulse Method : Gyro-Interaction of Radio-Waves obtained by the (Dr. Mario Cutolo), 834
Pulse Method for the Measurement of Ultrasonic Absorption in Liquids—Results for Water (J. M. M. Pinkerton), 128
Pulverized Fuel (T. F. Hurley), 318
Punjab Salt Range : Occurrence of Microflora in the Salt Pseudomorph Beds (A. K. Ghosh and A. Bose), 796
Purification of Humus and Allied Materials : Freezing as an Aid in the Drying and (Dr. W. G. C. Forsyth and G. K. Fraser), 607
Purification of Renin by means of Protein-Precipitating Agents (Dr. Tage Astrup and Aksel Birch-Andersen), 570
Pyrethrum in Kenya : A Disease of (Dr. R. M. Nattrass), 120
Pyruvate : Computation of the Free Energy of α-Ketoglutarate and, from Constants of the Transamination Process (S. Darling), 403
Pyruvic Acid : Optimum *p*H and Temperature, and Energy of Activation of the Transamination between Glutamic Acid and (S. Darling), 838

QUADRIVALENT Rhodium Complex : Isolation of a (Dr. F. P. J. Dwyer and R. S. Nyholm), 502
Quadrupole Moments (Nuclear) : Definition of (E. H. Rhoderick), 255
Qualitative Quanta, *review* by G. Wyllie, 692
Quality of Pain Sensibility : Significance of Multiple Innervation of Cutaneous Pain 'Spots' in relation to the (Dr. G. Weddell, D. C. Sinclair and W. H. Feindel), 27

Quanta : Qualitative, *review* by G. Wyllie, 692
Quantitative Aspects of Free Radical Chemistry (Prof. H. W. Melville), 778
Quantitative Estimation of Mixtures of Sugars by the Paper Chromatogram Method (A. E. Flood, Prof. E. L. Hirst and Dr. J. K. N. Jones), 86
Quantum : The Strange Story of the (Banesh Hoffmann), *review* by G. Wyllie, 692
Quantum Electrodynamics : Developments in (Prof. P. A. M. Dirac), 135
Quantum Mechanics : The Principles of (Prof. P. A. M. Dirac), third edition, *review* by Dr. W. Heitler, 812
Quartz in the Ultra-Violet Region : Temperature Coefficient of Rotation of (A. W. Crook and Prof. A. M. Taylor), 396
Quinine : Acquired Resistance (Twofold) to, in *Plasmodium gallinaceum* (Dr. A. Th. Knoppers), 606

RABBITS receiving Oral 'Gammexane' : Mortality of *Aedes aegypti* Feeding on (P. C. C. Garnham), 156
Radar : Dectection by, of a New Meteor Shower, 118
Radiant Temperatures of Walls in North-South and East-West Rooms (J. Neumann), 472
Radiation (Annihilation) : Angular Correlation Effects with (Prof. M. H. L. Pryce and J. C. Ward), 435
Radiation (Polarized) : Use of, in Infra-Red Analysis (Dr. G. B. B. M. Sutherland and A. Vallance Jones), 567
β- and γ-Radiation from U^{239} and Np^{239} (Prof. Hilding Slätis), 579
Radiation Damping Theory and the Propagation of Light (B. Ferretti and Prof. R. E. Peierls), 531
Radiation Pressure (Dr. Alexander R. Stokes), 532
Radiations from the Earth's Atmosphere (Prof. S. Chapman and D. R. Bates), 250
Radiations from Uranium (239) and Neptunium (239), (Prof. N. Feather), 749
Radical Chemistry (Free) : Quantitative Aspects of (Prof. H. W. Melville), 778
Radicals (Free) : A New Technique for Following the Attack of Metallic Mirrors by (Dr. G. Whittingham), 671
Radio : Earth, Stars and (Sir Edward Appleton), 283
  Information on Solar Activity by, 293
Radio Antennæ : Theory of, *review* by Dr. H. G. Booker, 277
Radio Disturbances : Solar and Terrestrial (J. S. Hey, S. J. Parsons and J. W. Phillips), 371
Radio Echoes from the Aurora Borealis (Dr. A. C. B. Lovell, J. A. Clegg and C. D. Ellyett), 372
Radio Echoes from Polar Auroras : Interpretation of (N. Herlofson), 867
Radio Fade-out, April 15, 1947 : Solar Limb Flare and Associated (E. T. Pierce), 59
Radio Frequencies : Relative Times of Arrival of Bursts of Solar Noise on Different (Ruby Payne-Scott, D. E. Yabsley and J. G. Bolton), 256
Radio-Frequency Ion Source with High Percentage Yield of Protons (J. G. Rutherglen and J. F. I.-Cole), 545
Radio-Frequency Noise Fluctuations and Chromospheric Flares : Solar (Dr. S. E. Williams), 708
Radio Reflexions from Meteoric Ionization (Physical Society discussion on), 74
Radio Transmission Lines and Wave Guides, *review* by Dr. R. L. Smith-Rose, 206
Radio-Waves : Gyro-interaction of, obtained by the Pulse Method (Dr. Mario Cutolo), 834
Radioactive Isotopes in Immunological Investigations : Use of (Dr. J. C. Boursnell, H. M. Dewey, Dr. G. E. Francis and Prof. A. Wormall), 339
Radioactive Sources : Application of the Cathode Ray Oscillograph to Measurements of Short Life-Periods of (Dr. S. Rowlands), 191
Radioactive Tracer Studies : Application of Filter Paper Partition Chromatography to (Dr. R. M. Fink, Dr. C. E. Dent and K. Fink), 801
Radioactivity : International Standards and Units of, 778
Radioactivity (Artificial) : The Application of, to Biology and Medicine (Dr. John H. Lawrence), 51
Radio-sodium in Isolated Muscle : Interpretation of the Exchange of (Dr. Hans H. Ussing), 262
Radish (*Raphanus sativus*) : Raphanin, an Antibacterial Principle of the (Prof. George Ivánovics and Stephan Horváth), 297
Rainfall Records of Australia, 393
Raman Spectra of Crystals : Second-Order (Dr. R. S. Krishnan), 230
Raman Spectrum of Alumina and the Luminescence and Absorption Spectra of Ruby (Dr. R. S. Krishnan), 26
Raman Spectrum of Crystals (Second-Order) : Temperature Variation in the (Prof. E. Gross and A. Stehanov), 568
Random Association of Points on a Lattice (P. V. Krishna Iyer), 714
Random Photovoltaic Barriers in Photoconductive Layers : Occurrence of (L. Sosnowski, B. W. Soole and J. Starkiewicz), 471
Raphanin, an Antibacterial Principle of the Radish (*Raphanus sativus*), (Prof. George Ivánovics and Stephan Horváth), 297
Rapid Method of Analysis for certain Surface-Active Agents (T. Barr, J. Oliver and W. V. Stubbings), 909
Rare-Earth Double Sulphates : Coprecipitation of Uranous Sulphate with (Dr. A. W. Wylie), 830
Raspberry Viruses (European) : Aphid Vectors of (C. H. Cadman and A. R. Hill), 837
Rat : Hypertension after Bilateral Nephrectomy in the (E. Braun-Menéndez and Prof. U. S. v. Euler), 905
Rat Diaphragm : Effect of Injection of Adrenaline on the Anerobic Glycolysis of (Dr. J. A. Cohen), 871
Rate of Formation of Phospholipids in the Liver : Influence of Choline and Ethanolamine on the (Dr. A. P. Platt and R. R. Porter), 905
Rats : Alloxan Diabetes and Glycogen Phosphorolysis in (Dr. D. Staehelin and Dr. W. Voegtli), 363
Rats (Adrenalectomized Lactating) : Decrease in the Arginase of the Liver and Mammary Gland in, as compared with Pair-fed Controls (Dr. S. J. Folley and A. L. Greenbaum), 364
Rats (White) : Nephrotoxic and Renotropic Effects of Lead on, and its Prevention by *B.A.L.* (Dr. Hugo Chiodi and Rodolfo A. Sammartino), 680
Raw Materials of Vegetable and Animal Origin : Crude Drugs and other, *review* by Dr. W. O. Howarth, 4
Rayleigh Line : Entropy Fluctuations in Liquid Helium II and the (B. K. Agarwala and A. G. Chowdri), 750
Rayon (Seaweed) : The Production, Properties and Uses of (Prof. J. B. Speakman), 373
R.C.A. Technical Papers : Index to Vol. 1, and Vol. 2a, 529
Reaction (Biuret) : An Improved, of Proteins and the Two-Standard Colorimetry (Dr. A. Sols), 89
Reaction between Catalase and Hydrogen Peroxide (Dr. P. George), 41
Reaction of Hydrogen Atoms with Solid Carbon (Prof. G. M. Harris and A. W. Tickner), 871
Reaction of Nitrous Acid with Chlorophyll (M. L. Sapiro), 796
Reaction of Tryptophane : A Fluorescent (Dr. J. V. Kostir), 266
Reaction for the D Vitamins : A New Colour (V. Villar Palasi), 88
Reactions : New Nuclear, 897
Reactions (Unimolecular) : Absolute Values of the Rates of (Dr. H. Pelzer), 576 ; (N. B. Slater), 576
Reactions of Carbon Compounds : The Development of Electrochemical Theories of the Course of (Sir Robert Robinson), 245
Reagents : Coiling of Wool Induced by certain (Martin R. Freney), 799
Real Variables : The Theory of Functions of (Prof. Lawrence M. Graves), *review* by T. M. M., 592
Reality : Science and (T. Bedford Franklin), *review* by F. Ian G. Rawlins, 349
Rearing Thrips in the Laboratory : Technique for (Dr. E. McC. Callan), 432
Reception : Transient, and the Degree of Resonance of the Human Ear (Dr. R. J. Pumphrey and T. Gold), 124
Recessiveness in the Human Blood Groups : Dominance and (Dr. A. E. Mourant), 353
Recruitment and Efficiency in the Civil Service, 239
Recrystallization of Aluminium : Growth of 'Stimulated Crystals' and Rate of Nucleation during (Prof. W. G. Burgers), 398
Rectifier Disks (Selenium) : Effect of Bending on (Dr. P. Sélenyi and Nicholas Székely), 197, *erratum*, 326
Red Locust (*Nomadacris septemfasciata*) in Africa, 1927–1945 : Migrations and Breeding of the (V. Morant), 67
Red Locust in Outbreak Areas and Elsewhere : The Habits and Control of the (A. P. G. Michelmore), 67
Red Pigment produced by a Strain of the *Penicillium nigricans-janczewskii* Series : A Fungistatic and Bacteriostatic (P. J. Curtis and J. F. Grove), 574
Red-Green Colour Vision Defects : Frequencies of Sex-Linked (Dr. R. W. Pickford), 335.
Reducing Value of Insects' Blood : Fructose and the (L. Levenbook), 465
Reduction : Activation of Copper by Oxidation and (F. C. Aldred and Dr. F. Happey), 267
Reduction of Aniline in Ammonia (Dr. Arthur J. Birch), 754
Reduction of Potassium Permanganate in the Presence of Glass (C. B. Taylor), 56
Redwood Medal of the Institute of Petroleum awarded to H. S. Gibson, 117
Reflexion : Total Internal, and Huyghens' Construction—the Immersion Grating (Dr. G. L. Rogers), 25
Refractive Index of Milk : Contribution of the Major Constituents to the (K. S. Rangappa), 719
Regionalism : City Region and (Robert E. Dickinson), *review*, 854
Register for the Year 1946 : The Annual (edited by H. T. Montague Bell), *review*, 735
Regulation of the Sodium-Potassium Ratio in Insects (Dr. G. J. Boné), 679
Rehabilitation : Medical, 220
Relapsing Fever Tick in African Houses : Economic Control of the (W. F. Jepson), 874
Relationship between the Dissociation Constants of Unsymmetrical Dicarboxylic Acids (Dr. D. H. R. Barton), 752
Relativity of Accelerated Motion (Dr. D. Meksyn), 834
Relaxation Methods, a Method for the Engineer (Dr. R. V. Southwell), 462
Renin : Purification of, by means of Protein-Precipitating Agents (Dr. Tage Astrup and Aksel Birch-Andersen), 570
Renotropic Effects of Lead on White Rats and its Prevention by *B.A.L.* : Nephrotoxic and (Dr. Hugo Chiodi and Rodolfo A. Sammartino), 680
Replacement of Fibres in Sheep (L. Auber and Macra Burns), 836
Reproduction in Woodlice : Abnormal (Dr. Walter E. Collinge), 509
Reproduction and Larval Development of Danish Marine Bottom Invertebrates (Dr. Gunnar Thorson), 766
Reptilian Testes : Absence of Hyaluronidase from (G. I. M. Swyer), 433
Research : Archæological, in South Africa, 393
  Co-operative, in Industry (Dr. D. W. Hill), *review* by R. Brightman, 346
  Glaciological (Gerald Seligman), 66
  Hop, in Britain, 668
  Management of, 547
  Market (Manchester Joint Research Council conference on), 686
  Operational, in War and Peace (British Association, Division of the Social and International Relations of Science, discussion on), 660
  Scientific, and Industrial Development in Scotland, 341
  Scientific and Industrial, in British Industry (Federation of British Industries), 770
  Scientific, and Public Expenditure, 849
  Typhus (Dr. G. Lapage), 726
Research (Botanical) : Co-operation in (Prof. C. W. Wardlaw), 804
  Co-operation versus Isolation in (Dr. I. W. Bailey), 804
Research (Industrial) : The Organisation of (Dr. R. P. Russell), 547
Research (Medical) : Beit Memorial Fellowships for, 152
Research (Scientific and Industrial) : Organisation for, 883
Research in Germany on the Technical Application of Atomic Energy (Prof. W. Heisenberg), 211
Research in the Jewellery Industry, 863
Research on Locusts : Recent (Dr. A. D. Imms), 67
Research on Toxicology, 634
Research Fellowship for work on the structure of the human foot (University College London and the British Boot, Shoe and Allied Trades Research Association), 497
Research Fellowships : Beit Memorial, 152
Research Fellowships, Leverhulme : Awards for 1947, 119
Research Scholarships, Leverhulme : To be awarded by the Royal College of Surgeons, 530

Research Studentships and Dominion and Colonial Exhibitions (Trinity College, Cambridge), 898
Research and Development in Great Britain : Government, 379
Research and Industry : X-Rays in (Dr. H. Hirst), second edition, *review* by Dr. W. A. Wood, 142
Research for Industry : 'Sponsored' (Sir Stafford Cripps), 150
Research and the Progress of Industry in Scotland (Federation of British Industries regional conference on), 341
Research Institutions (Scottish) : Science in Scotland, the Work of the (Dr. W. P. H. Wightman), 252
Reservoirs of Water, Wheat and Gold. *review* by Charles F. Carter, 383
Residual Effects in Titanates : Dielectric (Prof. J. R. Partington, G. V. Planer and I. I. Boswell), 877
Residual Lattice Strains in Plastically Deformed Metals (G. B. Greenough), 258
Resistance to *Antigastra* (Lepidoptera—Pyralidæ) Attack : Relation of Total Soluble Solids in the Cell Sap of *Sesamum* Species to the Degree of Susceptibility and (Dr. S. Mukherji), 95
Resistance (Twofold) to Quinine in *Plasmodium gallinaceum* : Acquired (Dr. A. Th. Knoppers), 606
Resistance Factor in the Albumin Residue revealed by the Serial Cephalin Flocculation Curve : A Non-Specific (Dr. Jack G. Makari), 201
Resonance : Gyromagnetic, in Ferrites (Dr. J. L. Snoek), 90
  Nuclear Magnetic, at Low Temperatures (B. V. Rollin, J. Hatton, A. H. Cooke and R. J. Benzie), 436
  Paramagnetic, and Magnetic Energy Levels in Chrome Alum (D. M. S. Bagguley and Dr. J. H. E. Griffiths), 532
Resonance of the Human Ear : Transient Reception and the Degree of (Dr. R. J. Pumphrey and T. Gold), 124
Resonant Cavity : Flow of Smoke through a Hole in (F. W. Simpson), 93 ; (Dr. Robert W. Lawson), 440
Respiration and Cell-Division in Eggs of the Sea Urchin, *Psammechinus miliaris* (Dr. Erik Zeuthen), 577
Response of New-born Children to Hypertonic Solutions of Sodium Chloride and of Urea (R. F. A. Dean and Prof. R. A. McCance), 904
Responsibility of Social Science (Dr. Louis Wirth), 622
Reticulo-Endothelial System : Histamine as a Physiological Activator of the (Dr. Miklós Jancsó), 227
Retina (*Vasa vasorum*) : Intramural Vessels in the (Prof. Arnold Loewenstein), 124
Retina (Human) : Some Fatigue Effects on the, produced by using Coloured Lights (Prof. H. Hartridge), 538
Retinal Pre-capillaries and Capillaries : Cushion Cells in (Prof. Arnold Loewenstein), 229
Rheological Behaviour and Classification (Prof. F. H. Garner and Dr. Afred H. Nissan), 329
Rheology of Clay : The Chemistry and (Rheological Club and the South-Western Branch of the Chemical Society discussion on), 511
Rhodium Complex (Quadrivalent) : Isolation of a (Dr. F. P. J. Dwyer and R. S. Nyholm), 502
Rhodnius prolixus (Hemiptera) : A Method for Observing Growing Epithelial Tissue in (Dr. M. Lüscher), 873
Ribonuclease : Demonstration of Bacterial Nuclei with (Dr. R. Tulasne and Dr. R. Vendrely), 225
Rice : Wild and Cultivated (Dr. C. D. Darlington), 756 ; (Dr. D. Chatterjee), 757
Rice (Milled Raw and Parboiled) : Thiamine of (Dr. Lucius Nicholls), 298
Rices (Wild and Cultivated) : Botany of the (Dr. D. Chatterjee), 234
Risk of Contamination in Experimental Carcinogenesis (Wm. Anderson), 338
Road Back to Health : The (Ministry of Health), 220
Road-making Materials : Mechanics of, *review*, 518
Role of Hydrogen in Combustion Systems : Use of a Palladium Tube Technique in the Study of the (J. R. Arthur and E. Sterling), 869
Romney Sheep (New Zealand) : Mendelian Inheritance in (Dr. F. W. Dry, A. Stewart Fraser and G. M. Wright), 646
Röntgenographisch-analytische Chemie (Prof. Dr. E. Brandenberger), *review* by Dr. M. F. Perutz, 208
Rook Behaviour during Incubation (C. M. Ogilvie), 563
Rooms (North-South and East-West) : Radiant Temperatures of Walls in (J. Neumann), 472
Rotating Knife : An Ensheathed, for Causing Brain Lesions (Dr. P. Glees, P. D. Wall and T. A. Wright), 365
Rotation of Quartz in the Ultra-Violet Region : Temperature Coefficient of (A. W. Crook and Prof. A. M. Taylor), 396
Rotatory Power : Optical, and Atomic Dimension (Dr. W. Gerrard and W. Lessing), 467
Royal Air Force : Education in the, 253
Royal Art of Astrology (Robert Eisler), *review* by Joshua C. Gregory, 276
Royal Institution : The Work of the, in Physical Chemistry in Great Britain (Prof. E. K. Rideal), 245
Royal Medals for 1947 of the Royal Society awarded to Prof. C. N. Hinshelwood and Dr. F. M. Burnet, 704, 839
Royal Society Empire Scientific Conference : Preliminary Report of the, 185
Royal Wedding : The, 667
Rubber : Synthetic, *review* by Prof. H. W. Melville, 851
Ruby : Raman Spectrum of Alumina and the Luminescence and Absorption Spectra of (Dr. R. S. Krishnan), 26
Ruffed Grouse : The (Henry Marion Hall), *review* by Frances Pitt, 418
Rust Fungi (Cereal) : Over-summering and Over-wintering of the (Dr. P. D. Critopoulos), 507
Rutherford Celebrations in Paris (Prof. M. L. Oliphant), 806

SALIVA/Cane-sugar Solutions : Acid Production in (E. Føyn and A. Hobaek), 758
Salivary Gland Chromosomes of *Anopheles* (Dr. Guido Frizzi), 226
Salmine : Constitution of (Dr. G. R. Tristram), 637
Salmon in the Sea : The Migrations of (J. W. Menzies), 33
Salt across the Frog Skin : Influence of Adenohypophysectomy on the Transfer of (C. Barker Jørgensen), 872
Salt Pseudomorph Beds, Salt Range, Punjab : Occurrence of Microflora in the (A. K. Ghosh and A. Bose), 796
Salt Solutions on Myosin : Electron Microscope Investigation of the Action of (Prof. Silvio Ranzi), 712
Salts : Interaction of Styrene with Magnesium Perchlorate and other (H. S. Lilley and G. L. Foster), 131
Sampling (Inverse) : Errors of Estimation in (D. J. Finney), 195
Schistocera gregaria in Eastern Africa : Seasonal Breeding and Migrations of the Desert Locust, (Z. Waloff), 67
Scholarship in Aeronautical Engineering for Women (Women's Legion and the Women's Engineering Society), 428
Scholarships : Leverhulme Research (To be awarded by the Royal College of Surgeons), 530
  Technical State, 394
School Broadcasting in Britain (Richard Palmer), *review*, 774
Schools (Secondary) : Examinations in (Secondary School Examinations Council report on), 497
Science : Some Economic Consequences of (Dr. Sumner H. Slichter), 622
  Ethics and (Conference on), 706
  The Expansion of the Scope of (Dr. Leslie A. White), 743
  Law-making in (Society for Visiting Scientists discussion on), 530
  The Missing Factor in (Prof. Herbert Dingle), 108, 613 ; (Prof. J. D. Bernal), 612
  The Place of Scientific Societies in the Promotion of (Dr. J. Ramsbottom), 343
Science in the Colonies (Dr. J. L. Simonsen), 284
Science in the New India (D. N. Wadia), 253
Science in Poland (Prof. Adam Malicki), 219
Science in Post-Primary Education (Association of Women Science Teachers Report, Part 3), 783
Science in Progress (Frank B. Jewett, James B. Macelwane, Donald W. Kerst, Hugh S. Taylor, L. Michaelis, Michael Heidelberger, G. W. Beadle, Peyton Rous, E. C. Stakman, Carl Caskey Speidel, Herbert M. Evans), edited by George A. Baitsell, Fifth Series, *review* by W. L. Sumner, 519
Science in Scotland, the Work of the Scottish Research Institutions (Dr. W. P. H. Wightman), 252, 341
Science and the Soviet State (Society for Cultural Relations with the U.S.S.R. (Science Section) symposium on), 636
Science in the U.S.S.R., 636
Science in War and Peace (Sir Henry Dale), 280
Science and the Creative Arts (W.B.Honey), *review* by F. Ian G. Rawlins, 418
Science, Government and Industry (Sir Edward Appleton), 850
Science and Industry : Dutch Pioneers in, *review* by Lieut.-Colonel Ernest Tillotson, 449
Science, Liberty and Peace (Aldous Huxley), 172 ; *review* by R. Brightman, 733
Science and Life in the World (George Westinghouse Centennial Forum, May 16–18, 1946), Vol. 1, Science and Civilization ; The Future of Atomic Energy ; Vol. 2, Transportation—a Measurement of Civilization ; Light, Life and Man ; Vol. 3, A Challenge to the World ; *review* by W. L. Sumner, 141
Science and Peace, *review* by R. Brightman, 733
Science and Philosophy : Essays in (Alfred North Whitehead), *review* by Sir Edmund Whittaker, 415
Science and Reality (T. Bedford Franklin), *review* by F. Ian G. Rawlins, 349
Science and Technical Education in Germany, 721
Scientific Approach to the Lace Industry, 879
Scientific Development in China, 600
Scientific Freedom *versus* Secrecy, 311
Scientific Journals : New, 394
Scientific Knowledge : Publication and Classification of (Association of Scientific Workers, Cambridge Senior Branch, conference on), 496, 649
Scientific Library in London : French, 669
Scientific Mission for London : American, 633
Scientific Organisation and Management, 729
Scientific Research and Industrial Development in Scotland, 341
Scientific Research and Industry : International Exhibition of, 766
Scientific Research and Public Expenditure, 849
Scientific Service (Government) : Conditions in the, 392
Scientific Societies : British (Royal Society to compile a list of), 898
  Local (Dr. J. Ramsbottom), 290
Scientific Societies in the Promotion of Science : The Place of (Dr. J. Ramsbottom), 343
Scientific and Industrial Research : Organisation for, 883
Scientific and Industrial Research in British Industry (Federation of British Industries), 770
Scientific and Technical Papers (German) : Photostat Copies of, 427
Scientific and Technological Man-Power in Great Britain, 742
Sclerotinia Porri on *Allium* spp. in England (James F. H. Cronshey), 798
Scope of Science : The Expansion of the (Dr. Leslie A. White), 743
Scotland : Industry and Employment in (Scottish Office report on), 341
  National Parks and the Conservation of Nature in (Report of the Scottish National Parks Committee on), 809
  Research and the Progress of Industry in (Federation of British Industries regional conference on), 341
  Science in, the Work of the Scottish Research Institutions (Dr. W. P. H. Wightman), 252, 341
  Scientific Research and Industrial Development in, 341
Scottish Research Institutions : Science in Scotland, the Work of the (Dr. W. P. H. Wightman), 252, 341
Sea : The Migrations of Salmon in the (J. W. Menzies), 33
Sea Birds : British (C. A. Gibson-Hill), *review* by R. M. Lockley, 591
Sea Level : Origin of Cosmic Ray Stars at (D. H. Perkins), 707
Sea Urchin, *Psammechinus miliaris* : Respiration and Cell-Division in Eggs of the (Dr. Erik Zeuthen), 577
Sea Waves and Microseisms : Relations between (Dr. G. E. R. Deacon), 419
Seaweed : Industrial Utilization of Agricultural Products and of (Irish Chemical Association and the Dublin Section of the Royal Institute of Chemistry colloquium on), 373
Seaweed Rayon : The Production, Properties and Uses of (Prof. J. B. Speakman), 373
Seaweed Research : The Institute of (Dr. H. R. Fletcher), 662
'Second Meson' Events : Hypothetical Alternative Energy Sources for the (Dr. F. C. Frank), 525
Secondary Education in Britain : The Evolution of (Lynda Grier), 289
Secondary Schools : Examinations in (Secondary School Examinations Council report on), 497
Secrecy : Scientific Freedom *versus*, 311

Sedimentation Phenomenon : A (R. Johnson and Dr. F. Smithson), 26
Seedling Growth : Toxic Effects of Amino-Acids and Amines on (Dr. L. J. Audus and Prof. J. H. Quastel), 222
Seismic Aspects of the Heligoland Explosion (P. L. Willmore), 350
Seismological Observatories : New, 530
Seismology at Oxford, 220
Selection for Management (British Association for the Advancement of Science, Section J (Psychology) discussion on), 512
Selective Toxic Action of Thiosulphate on Plants (Dr. L. J. Audus and Prof. J. H. Quastel), 263
Selenium Rectifier Disks : Effect of Bending on (Dr. P. Selényi and Nicholas Székely), 197, *erratum*, 326
Self-Sterility Alleles : Number of (Prof. R. A. Fisher), 797
Semi-Quinonoid Oxidation Product of 4 : 4-Diethoxydinaphthyl (G. Baddeley, P. Graddon and Prof. J. Kenner), 187
Seminal Fructose : Effect of Testicular Hormone on the Formation of (Dr. T. Mann and Ursula Parsons), 294
Serial Cephalin Flocculation Curve : A Non-Specific Resistance Factor in the Albumin Residue revealed by the (Dr. Jack G. Makari), 201
Serial Dilution Technique in Microbiological Assays : General Equation for the (A. M. Wild), 57
Serum Proteins : Fractional Precipitation of (Dr. Tage Astrup and Aksel Birch-Andersen), 637
Servo (Human) : The Design and Performance of the (Dr. J. A. V. Bates), 341
Servo Mechanisms : Automatic Regulators and (Institution of Electrical Engineers convention on), 340
Servo Simulators : Electronic (Prof. F. C. Williams), 340
Sesamum Species : Relation of Total Soluble Solids in the Cell Sap of, to the Degree of Susceptibility and Resistance to *Antigastra* (Lepidoptera-Pyralidæ) Attack (Dr. S. Mukherji), 95
Sesamum orientale L. : Leaf Heteromorphism and Photoperiods in (Prof. J. C. Sen Gupta and Santosh Kumar Payne), 510
Sewage Sludges : Estimation of Potassium in (P. Garrick), 434
Sex Reversal : Abnormal Flower Development in Barley involving (Prof. F. G. Gregory and O. N. Purvis), 221
Sex Reversal in *Patella coerula* L. and *Diodora gibberula* (Lam.), (G. Bacci), 94
Sex-Linked Red-Green Colour Vision Defects : Frequencies of (Dr. R. W. Pickford), 335
Sex-linked and Sex-limited White-eyed Mutation of the Blow-fly (*Calliphora erythrocephala*), (Dr. P. Tate), 361
Sheep : Influence of Variation in Length of Day upon the Breeding Season in (N. T. M. Yeates), 429
  Replacement of Fibres in (L. Auber and Marca Burns), 836
Sheep (New Zealand Romney) : Mendelian Inheritance in (Dr. F. W. Dry, A. Stewart Fraser and G. M. Wright), 646
Shells and Pearls of *Tridacna squamosa* Lam. and *Hippopus hippopus* (Linn.) : On the Structure of the (Dr. A. Reyne), 653
Ships : Reduction of Fire Risks in (Dr. L. A. Jordan), 216
Shirley Fellowship of the British Cotton Industry Research Association awarded to B. J. Mason, 428
Shock Wave in Glass (K. M. Baird), 24
Shock Wave Phenomena (American Physical Society symposium on), 530
Shock Wave Systems from Detonating Explosives : Mach Waves in (D. W. Woodhead and R. Wilson), 672
Shock-induced Stomatal Movements (W. T. Williams), 364
Short Life-Periods of Radioactive Sources : Application of the Cathode Ray Oscillograph to Measurements of (Dr. S. Rowlands), 191
Short-style Gene : Spontaneous Occurrence in *Lythrum salicaria* of Plants Duplex for the (Prof. R. A. Fisher and V. C. Martin), 541
Shorthorn Cow : A Tri-colour (Mosaic), (I. Chester Jones), 337
Shrews : Tuberculosis of Voles and (Dr. G. Lapage), 687
Shrubs and Trees as Fodder : The Use and Misuse of (Imperial Agricultural Bureaux Joint Publication No. 10), 862
Side-chains in Amylopectin : Structure of Starch—Mode of Attachment of the (T. G. Halsall, Prof. E. L. Hirst, Dr. J. K. N. Jones and A. Roudier), 899
Silicon Flame Bands (A. R. Downie and R. F. Barrow), 198
Silicon-Metal Contact Resistance : A (E. H. Putley), 710
Skin : Atlas of Histopathology of the (Prof. G. H. Percival, Prof. A. Murray Drennan and T. C. Dodds), *review*, 553
Skin (Frog) : Influence of Adenohypophysectomy on the Transfer of Salt across the (C. Barker Jørgensen), 872
Skin (Guinea Pig's) : Role of Dendritic Cells in the Infective Colour Transformation of (R. E. Billingham and Prof. P. B. Medawar), 61
Sky : The Night, in August 119 ; in September, 293 ; in October, 428 ; in November, 564 ; in December, 744
Sky and Aurorae (Night) : Emission Spectra of the (Royal Society, Gassiot Sub-Committee B, conference on), 16
Sikilsdalen og Norges fjellbeiter (Prof. Rolf Nordhagen), *review* by Prof. I. Manton, 4
Silicic Acid (Prof. F. H. Constable and S. Tegul), 55
Sligo : Cobalt Deficiency in (Dr. E. J. Sheehy), 873
Slip Flow in Granular Beds (Dr. P. C. Carman), 301
Slow Mesons in Photographic Emulsions : Observations on the Tracks of (C. M. G. Lattes, Dr. G. P. S. Occhialini and Dr. C. F. Powell), 453, 486
Sludges (Sewage) : Estimation of Potassium in (P. Garrick), 434
Small-size Plots in Yield Surveys : Use of (Dr. P. V. Sukhatme), 542
Smears of Titanium Metal (Dr. W. A. Wooster and G. L. Macdonald), 260
Smoke : Flow of, through a Hole in Resonant Cavity (F. W. Simpson), 93 ; (Dr. Robert W. Lawson), 440
Snowy River Region of Victoria, Australia, 48
Soap Film Method : A New Apparatus for Gas Analysis by the (W. J. Gooderham), 441
Social Biology : International School in (British Social Hygiene Council), 803
Social Change : Psychology of (Prof. Donald C. Marquis), 622
Social Evils in Switzerland : Some Ways of Facing (Dr. H. Revilliod), 803
Social Improvement by Education, *review*, 625
Social Psycho-Hygiene (Dr. St. Zurukzoglu), 803
Social Science : Anthropological Approach in (Prof. C. Daryll Forde), 286
  Responsibility of (Dr. Louis Wirth), 622
Social Sciences as a Factor in International Collaboration, 103
Social Workers : Training of, 137
  Report on the Employment and Training of (Eileen L. Younghusband), 137
Social and Economic Aspects of National Health : Present-Day (American Philosophical Society symposium on), 360
Society and the Individual (British Social Hygiene Council conference on), 706
Sociological Significance of Language and Culture, 205
Sociology : Current Aspects of (*Pilot Papers*, Vol. 2, No. 1), 219
Na_2, K_2 and NaK : Absorption Bands of Li_2, (Dr. R. W. B. Pearse and S. P. Sinha), 159
NaK : Absorption Bands of Li_2, Na_2, K_2 and (Dr. R. W. B. Pearse and S. P. Sinha), 159
Sodium Chloride and of Urea : Response of New-born Children to Hypertonic Solutions of (R. F. A. Dean and Prof. R. A. McCance), 904
Sodium Citrate : Stabilization of Penicillin-Salt Solutions with (Dr. L. Hahn), 639
Sodium-Potassium Ratio in Insects : Regulation of the (Dr. G. J. Boné) 679
Soil : Effect of Cetyl Pyridinium Bromide on the Water Absorption and Swelling of (K. E. Clare), 828
Soil in Civil Engineering (A. H. Toms,) 343
Soil Mechanics and Foundation Engineering : Second International Conference on, 360
Soil Surveys in the Caribbean, 634
Soil and Land Classification : Problems of (British Society of Soil Science conference on), 686
Soils, Concrete and Bituminous Materials, *review*, 518
Soils and Health (Dr. W. G. Ogg), 290
Sol/Gel Transformation of Blood Plasma *in vitro* : Influence of Hydrotropic Substances on the (Dr. Ch. Wunderly), 228
Solar Activity by Radio : Information on, 293
Solar Eclipse of May 20 : Total (Preliminary Reports of the), 49
Solar Limb Flare and Associated Radio Fade-out, April 15, 1947 (E. T. Pierce), 59
Solar Noise on Different Radio Frequencies : Relative Times of Arrival of Bursts of (Ruby Payne-Scott, D. E. Yabsley and J. G. Bolton), 256
Solar Phenomenon in High Latitude : A Short-lived (Dr. A. D. Thackeray), 439
Solar Radiation on 175 Mc./s and 80 Mc./s : Relation between the Intensity of (M. Ryle and D. D. Vonberg), 157
Solar Radiation Work : Unit for (Loyal B. Aldrich, Dr. Harry Wexley, Sigmund Fritz, I. F. Hand, Arnold Court and William P. Millen), 327
Solar Radio-Frequency Noise Fluctuations and Chromospheric Flares (Dr. S. E. Williams), 708
Solar and Lunar Diurnal Magnetic Variations : Location of the Currents causing the (Dr. D. F. Martyn), 535
Solar and Terrestrial Radio Disturbances (J. S. Hey, S. J. Parsons and J. W. Phillips), 371
Solar Spectrum (Infra-Red) : Use of the Cathode Ray Oscillograph for Studying the near (A. U. Momin), 130
Solar Variation of 6.6456 Days (Dr. C. G. Abbot), 49
Solid Carbon : Reaction of Hydrogen Atoms with (Prof. G. M. Harris and A. W. Tickner), 871
Solids : Conduction of Heat in (Prof. H. S. Carslaw and J. C. Jaeger), *review* by Prof. L. Rosenhead, 886
Solids (Total Soluble) : Relation of, in the Cell Sap of *Sesamum* Species to the Degree of Susceptibility and Resistance to *Antigastra* (Lepidoptera—Pyralidæ) Attack (Dr. S. Mukherji), 95
Solution of a Four-cusped Wake : Analytical (Dr. D. N. de G. Allen), 509
Solutions : Use of Filter Paper Pellets in the Spectrochemical Analysis of (Prof. N. S. Bayliss and D. J. David), 334
Solutions of Acrylonitrile (Dilute Aqueous) : Effect of Gamma- and X-Rays on (Dr. F. S. Dainton), 268
Soochow Astronomical Chart (W. Carl Rufus and Hsing Chih Tien), *review*, 279
Sound Emitted by Dolphins (B. Kullenberg), 648 ; (Dr. F. C. Fraser), 759
Sound-Films : Photo-electric Fourier Transformer and its Application to (Dr. D. Brown and J. W. Lyttleton), 709
South Africa : Archæological Research in, 393
  D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in (Dr. P. J. du Toit), 485
South-East England : Some Archæological Problems in (Dr. A. E. Wilson), 343
South-Eastern United States : Indians o the (John R. Swanton), 898
Soviet Philosophy (Dr. John Somerville), *review* by Lord Lindsay of Birker, 36
Soviet State : Science and the (Society for Cultural Relations with the U.S.S.R. (Science Section), symposium on), 636
Soviet Union : The Population of the (Frank Lorimer), *review* by Prof. H. J. Fleure, 888
Space-Charge Lens for the Focusing of Ion Beams (Dr. D. Gabor), 89
Spark Discharge : The (Physical Society discussion on), 110
Special Libraries in Australia, 897
Speciation in Cichlid Fishes of East African Lakes (Dr. Ethelwynn Trewavas), 96
Specimen Changes due to Electron Bombardment in the Electron Microscope (Prof. E. F. Burton, R. S. Sennett and S. G. Ellis), 565
Spectra : Absorption, with Polarized Infra-Red Radiation (J. Mann and Dr. H. W. Thompson), 17
  Emission, of the Night Sky and Aurarae (Royal Society, Gassiot Sub-Committee B, conference on), 16
  Vibration, of the Alkali Halides (Prof. R. S. Krishnan), 711
Spectra of Ruby (Absorption) : Raman Spectrum of Alumina and the Luminescence and (Dr. R. S. Krishnan), 26
Spectral Lines : Structure of, *review* by Dr. D. A. Jackson, 244, 909; (Prof. S. Tolansky), 909
Spectrochemical Analysis : Index to the Literature on, Part 2, 1940–1945 (American Society for Testing Materials), 563
Spectrochemical Analysis of Solutions : Use of Filter Paper Pellets in the (Prof. N. S. Bayliss and D. J. David), 334
Spectroscopy : High Resolution (Dr. S. Tolansky), *review* by Dr. D. A. Jackson, 244
Spectroscopy (Infra-Red) : Lead Selenide Cells for (D. E. Blackwell, O. Simpson and Dr. G. B. B. M. Sutherland), 793
Spectrum : Raman, of Alumina and the Luminescence and Absorption Spectra of Ruby (Dr. R. S. Krishnan), 26

Spectrum (Infra-Red Solar) : Use of the Cathode Ray Oscillograph for Studying the near (A. U. Momin), 130
Spectrum of ρ-Cassiopeiæ (Dr. A. D. Thackeray), 370
Speed Around the Initiating Point of the Detonation Wave in High Explosives (W. C. F. Shepherd), 92
Spermatozoal Motility in Dilute Suspension : Maintenance of (Dr. C. W. Emmens and G. I. M. Swyer), 718
Spherical Electronic Waves ? (W. E. Benham), 160
Spermatogenesis : Functional Development of Accessory Glands and (Dr. D. V. Davies and Dr. T. Mann), 295
Spiral Cracks in Glass Tubing (I. C. P. Smith), 232
Spoilage of Canned Foods : Infected Cooling Water and its Effect on the (T. E. Bashford), 584
'Sponsored' Research for Industry (Sir Stafford Cripps), 150
Spontaneous Electrical Fluctuations in Thermionic Valves : A Unified Theory of (Dr. R. Fürth), 832
Spontaneous Emission of Neutrons by Uranium X : Evidence against (Dr. Hl. de Vries and H. Groendijk), 435
Spores in *Verticillium* and some other Genera of the Hyphomycete Fungi : Passive Movements of Newly Formed Acrogenous (C. J. La Touche), 679
Stabilization of Penicillin-Salt Solutions with Sodium Citrate (Dr. L. Hahn), 639
Standardization in Industry (Percy Good), 618
Standardizing Liver Extracts : A Microbiological Method of (Prof. S. Mahdihassan and Vasudev M. Bakshi), 404
Staphylococcus aureus : Correlation between Penicillin Resistance and Assimilation Affinity in (Dr. Ernest F. Gale), 407
Star Positions, *review* by Dr. M. Davidson, 519
Starch : Structure of—Mode of Attachment of the Side-chains in Amylopectin (T. G. Halsall, Prof. E. L. Hirst, Dr. J. K. N. Jones and A. Roudier), 899
Starch (Native) : Configuration and Packing of Chain Molecules of, in the B-Modification (Dr. D. Kreger), 369
Starch Hydrolysis by Polarised Light (Dr. Elizabeth S. Semmens), 669
Stars : Chemical Composition of the (F. Hoyle), 744
Stars, 1947 (Fundamental) : Apparent Places of, *review* by Dr. M. Davidson, 519
Stars and Radio : Earth, (Sir Edward Appleton), 283
State Scholarships : Technical, 394
Statistical Criterion to Determine the Group to which an Individual Belongs (C. Radhakrishna Rao), 835
Statistical Methods in Germany (Dr. S. Vajda), 724
Statistics (Mathematical) : Introduction to (Assoc. Prof. Paul G. Hoel), *review* by David G. Kendall, 625
Steel (Mild) : Anodic Behaviour of, in Strongly Alkaline Solutions (Chas. D. Weir), 259
    X-Ray Diffraction Studies of Yielding in (Dr. E. W. Fell), 259
Steel Industry : Physics and the, 684
Steels (Plain Carbon) : Structure of Retained Austenite in (Dr. W. J. Wrazej), 93
Steepest Descents to X-Ray Structure Analysis : Application of the Method of (A. D. Booth), 196
Stemphylium : Danish Species of *Alternaria* and (Paul Neergaard), *review* by Dr. S. P. Wiltshire, 313
Steric Hindrance : *neo*Pentyl Alcohol and (I. Dostrovsky, Prof. E. D. Hughes and Prof. C. K. Ingold), 901
Sterility : Adolescent (Prof. M. F. Ashley-Montagu), *review* by Prof. S. Zuckerman, 591
Sterkfontein Ape-man (Male) : Jaw of the (Dr. R. Broom and J. T. Robinson), 153
Sterkfontein Ape-man, *Plesianthropus* : Further Remains of the (Dr. R. Broom and J. T. Robinson), 430
Stilbamidine : Constitution of the Irradiation Product from (Dr. J. D. Fulton and Dr. J. D. Dunitz), 161
'Stimulated Crystals' and Rate of Nucleation during Recrystallization of Aluminium : Growth of (Prof. W. G. Burgers), 398
Stock-Raising : Straightforward Instruction in, *review* by Prof. J. E. Nichols, 347
Stockbreeding and the Artificial Insemination of Livestock (V. K. Milovanov and I. I. Sokolovskaya), translated by Dr. A. G. Morton, *review* by John Hammond, 209
Stockfish (Dehydrated) : Critical Moisture Content of (G. F. van Wyk), 872
Stomatal Movements : Shock-Induced (W. T. Williams), 364
Stored Foods : Pests of (Food and Agriculture Organisation of the United Nations conference on), 51, 739
Strains and Displacements in Stress-Strain Problems : Large (Dr. K. H. Swainger), 399
Strawberry Virus Diseases : Etiology of (Dr. Conway A. Wood and Dr. T. Whitehead), 761
Streams : Some Aspects of the Bacteriology of Lakes and (Dr. C. B. Taylor), 584
Stress : Tensile, as a Factor in Fern Phyllotaxis (Prof. C. W. Wardlaw), 678
Stress-Strain Problems : Large Strains and Displacements in (Dr. K. H. Swainger), 399
Structure of Amylopectin (Prof. Kurt H. Meyer, P. Gürtler and Dr. P. Bernfeld), 900 ; (Sir W. Norman Haworth), 901
Structure of Cyclopropane (Dr. H. A. Skinner), 902 ; (Dr. A. D. Walsh), 902
Structure of Cyclopropane and Ethylene Oxide (T. M. Sugden), 367
Structure of Dimethylnitramine (Dr. W. Costain and Prof. E. G. Cox), 825
Structure of Ethylene Oxide and Cyclopropane (Dr. J. W. Linnett), 162
Structure of the Liver Cell in Pregnancy : Composition and (Dr. H. W. Kosterlitz and Rosa M. Campbell), 676
Structure of Phthiocerane (Molecular) : Infra-Red Spectrum and (S. Ställberg-Stenhagen and Prof. E. Stenhagen, and N. Sheppard, Dr. G. B. B. M. Sutherland and A. Walsh), 580
Structure of the Shells and Pearls of *Tridacna squamosa* Lam. and *Hippopus hippopus* (Linn.) : On the (Dr. A. Reyne), 653
Structure of Spectral Lines, *review* by Dr. D. A. Jackson, 244, 909 ; (Prof. S. Tolansky), 909
Structure of Starch—Mode of Attachment of the Side-chains in Amylopectin (T. G. Halsall, Prof. E. L. Hirst, Dr. J. K. N. Jones and A. Roudier), 899
Structure of the Sydnones : Dipole Moments and (Prof. Wilson Baker, W. D. Ollis, V. D. Poole, J. A. Barltrop, R. A. W. Hill and L. E. Sutton), 366
Structure and Diamagnetic Susceptibility of Cyclo-octatetraene (R. C. Pink and Prof. A. R. Ubbelohde), 502
Structure and Physical Properties of Metals (Institute of Physics, Midland Branch and the X-Ray Analysis Group, joint conference on), 601
Structure Analysis (X-Ray) : Application of the Method of Steepest Descents to (A. D. Booth), 196
Structure-Factors : Relations between (Dr. J. Gillis), 866
Structures : The Experimental Study of (Prof. A. J. S. Pippard), *review* by E. K. Frankl, 349
Structures Produced in Clays by Electric Potentials and their relation to Natural Structures (Leo Casagrande), 470
Students (Medical) : Biology for (C. C. Hentschel and Dr. W. R. Ivimey Cook), fourth edition, *review* by A. S., 853
Students in British Universities, 861
Studentships : Research, and Dominion and Colonial Exhibitions (Trinity College, Cambridge), 898
Styrene with Magnesium Perchlorate and other Salts : Interaction of (H. S. Lilley and G. L. Foster), 131
Sublimation in Outdoor Air (Dr. B. M. Cwilong), 198
Substances (Dissolved) : Diffusion of, through Thalli and Leaves of Aquatic Plants (Prof. E. Steemann Nielsen), 376
Substrate of Enzyme Action : Mucin as, by Viruses of the Mumps Influenza Group (Dr. F. M. Burnet, J. F. McCrea and S. G. Anderson), 404
Succinate and α-Glycerophosphate Oxidase Systems : The Constitution of the (Dr. A. O. M. Stoppani), 52
Sudan : Relationship of Mosquitoes and Yellow Fever in the (Dr. J. Lewis), 185
Sugar Concentration : Influence of the, on the Growth of Isolated Pine Roots (V. Slankis), 645
Sugars : Quantitative Estimation of Mixtures of, by the Paper Chromatogram Method (A. E. Flood, Prof. E. L. Hirst and Dr. J. K. N. Jones), 86
Sugars separated on the Filter Paper Chromatogram : Micro-Estimation of (J. R. Hawthorne), 714
Sulphatase of Clarase (Dr. L. M. Dzialoszynski), 464
Sulphate-reducing Bacteria : Autotrophic Growth of (K. R. Butlin and M. E. Adams), 154
Sulphates (Rare-Earth Double) : Coprecipitation of Uranous Sulphate with (Dr. A. W. Wylie), 830
Sun's Equilibrium : The Matter-Radiation Cycle in the Cosmos (and the Second 'Law')—the (Alfred Lauck Parson), 906
Sun's Rays : Angle of Incidence of the (P. J. H. Unna), 713
Sun-Bathing by Birds (John Gibb), 785
Sunlight : Dimerization Reactions in (Prof. Alexander Schönberg, Ahmed Mustafa and Mohamed Zaki Barakat), 401
Superconductors : Penetration of Magnetic Field into (E. Laurmann and Dr. D. Shoenberg), 747
Superman : The Cult of the (Eric Bentley), *review* by A. D. R., 592
Supersonic Speed Flight Investigation, 529
Superstition : Onslaught on a, *review* by Joshua C. Gregory, 276
Surface Areas : Calculation of, from Measurements of Negative Adsorption (Dr. R. Kenworthy Schofield), 408
Surface Deposits of D.D.T. on Mud : Insecticidal Effect of (A. B. Hadaway and F. Barlow), 363
Surface Phenomena : Physics of (American Physical Society symposium on), 530
Surface Phenomenon on Flowing Water : The 'Floating Thread', a (I. Kuščer), 673
Surface Tension in Liquids (C. Gurney), 166
Surface Tension and Detergency (Dr. C. C. Addison), 467
Surface-Active Agents : A Rapid Method of Analysis for certain (S. R. Epton), 795 ; (T. Barr, J. Oliver and W. V. Stubbings), 909
Susceptibility and Resistance to *Antigastra* (Lepidoptera—Pyralidæ) Attack : Relation of Total Soluble Solids in the Cell Sap of *Sesamum* Species to the Degree of (Dr. S. Mukherji), 95
Suspension (Dilute) : Maintenance of Spermatozoal Motility in (Dr. C. W. Emmens and G. I. M. Swyer), 718
Sussex : Some Orchids of Kent and (E. J. Bedford), 343
Sussex and Normandy in Norman Times (J. E. Ray), 343
Swedish Deep-Sea Expedition (Prof. Hans Pettersson), 559
Swelling of Soil : Effect of Cetyl Pyridinium Bromide on the Water Absorption and (K. E. Clare), 828
Swiss Earthquakes during 1945, 636
Switzerland : Some Ways of Facing Social Evils in (Dr. H. Revilliod), 803
Swords into Ploughshares, 273
Symbiosis : Nutrition and (Dr. E. C. Owen), 78
Symbiosis in *Oliarius* (Prof. P. Buchner), 264
Sydnones (Prof. J. C. Earl, Eleanor W. Leake and Prof. R. J. W. Le Fèvre), 366
    Dipole Moments and Structure of the (Prof. Wilson Baker, W. D. Ollis, V. D. Poole, J. A. Barltrop, R. A. W. Hill and L. E. Sutton), 366
Syntheses (Enzymatic) : Aspects of the Biological Function of Phosphate in (Dr. Herman M. Kalckar), 143
Synthesis : Phenazine (Prof. G. R. Clemo and A. V. Daglish), 752
Synthesis of the Antibiotic, Penicillic Acid (R. A. Raphael), 261
Synthesis of Cholesterol : Towards the (Dr. J. W. Cornforth and Sir Robert Robinson), 737
Synthesis of Cyclic Conjugated Polyolefins (D. H. S. Horn, J. R. Nunn and Dr. W. S. Rapson), 829
Synthesis of Phospholipids in the Fœtus (G. Popják), 841
Synthesis of Vitamin A Aldehyde (Dr. D. A. van Dorp and Dr. J. F. Arens), 189
Synthetic Œstrogens in Man : Metabolism of (Dr. A. E. Wilder Smith), 787
Synthetic Rubber, *review* by Prof. H. W. Melville, 851
Synthetic Vitamin K Substitute : Combination of some Effects of X-Radiation and a (Prof. J. S. Mitchell and Mrs. I. Simon-Ruess), 98

TANTALUM : Annealing Temperature and Hardness of (Prof. J. Neill Greenwood and R. H. Myers), 675
Taraxerol : A New Source of (W. J. Dunstan, G. K. Hughes and N. L. Smithson), 577
Taxonomy : The Principles and Methods of (Linnean Society in conjunction with the Systematics Association course of lectures on), 564
Teachers in Technical Colleges and Schools, 549
Teaching in Agriculture and Horticulture : University, 151
Teaching of Physiology : Wider Applications of (Prof. Winifred Cullis), 287
Teak Forests of Burma (Prof. E. P. Stebbing), 818
Technical Application of Atomic Energy : Research in Germany on the (Prof. W. Heisenberg), 211
Technical Colleges and Schools : Teachers in, 549
Technical Education : International Congress at the Technische Hochschule, Darmstadt (James T. Kendall), 721
Technical Education in Germany : Science and, 721
Technical Journals : Paper for (H. Wilson), 636
Technical State Scholarships, 394
Technicians (Laboratory) : Education and Training of, 635
Technique of the Analysis of Variance (Dr. S. Vajda), 27 ; (Dr. F. Yates), 472
Technique of X-Ray Powder Photography (H. P. Rooksby), 7
Technological Man-Power in Great Britain : Scientific and, 742
Technology : X-Ray Analysis as a Tool in Chemistry and, *review* by Dr. M. F. Perutz, 208
Teleostean Fish (Hermaphrodite) : Influence of Hypophyseal Hormone and of Nervous Impulses on the Colour-dress of (Dr. O. Peczenik and M. Zei), 788
Television : Pioneering in (Brig.-General David Sarnoff), 118
  Plastic Optical Systems for (Dr. D. Starkie), 99
  Bibliography of Technical Papers on (Radio Corporation of America), 118
Television in the United States, 118
Temnocephala novae-zealandiae Haswell : Embryology of (Roy A. Harrison), 798
Temperature : Optimum *p*H and, and Energy of Activation of the Transamination between Glutamic Acid and Pyruvic Acid (S. Darling), 838
Temperature Coefficient of Rotation of Quartz in the Ultra-Violet Region (A. W. Crook and Prof. A. M. Taylor), 396
Temperature Variation of the Second-Order Raman Spectrum of Crystals (Prof. E. Gross and A. Stehanov), 568
Temperatures (Low) : Nuclear Magnetic Resonance at (B. V. Rollin, J. Hatton, A. H. Cooke and R. J. Benzie), 436
Temperatures of Walls : Radiant, in North-South and East-West Rooms (J. Neumann), 472
Tensile Stress as a Factor in Fern Phyllotaxis (Prof. C. W. Wardlaw), 678
Terpene Chemistry, *review* by Prof. John Read, 384
Terpene-type Essential Oil from a Fern (*Paesia scaberula*) : A (Dr. Lindsay H. Briggs and Maurice D. Sutherland), 333
Terpenes ; The (Dr. J. L. Simonsen), Vol. I, The Simpler Acyclic and Monocyclic Terpenes and their Derivatives, second edition, revised by Dr. L. J. Simonsen and Dr. L. N. Owen, *review* by Prof. John Read, 384
Terrestrial Conditions : Thermo-nuclear Reactions under (Dr. J. H. J. Poole), 635
Terrestrial Magnetism : Frenkel's views on the Origin of (Prof. Louis B. Slichter and Dr. E. C. Bullard), 157
Terrestrial Radio Disturbances : Solar and (J. S. Hey, S. J. Parsons and J. W. Phillips), 371
Testes (Reptilian) : Absence of Hyaluronidase from (G. I. M. Swyer), 433
Testicular Hormone on the Formation of Seminal Fructose : Effect of (Dr. T. Mann and Ursula Parsons), 294
Tetrachoric Correlation Coefficient : Nomogram for the (Max Hamilton), 473
Text-book Organic Chemistry (A. T. Austin; Prof. E. D. Hughes and Prof. C. K. Ingold), 406 ; (Dr. Neil Campbell), 875
Textile Industry and the University of Leeds, 185
Thalli and Leaves of Aquatic Plants : Diffusion of Dissolved Substances through (Prof. E. Steemann Nielsen), 376
Theoretical Foundations of Process Control (G. H. Farrington), 340
Theoretical Physics at Manchester, 83
Theory of Functions of Real Variables (Prof. Lawrence M. Graves), *review* by T. M. M., 592
Theory of Nuclear Forces : Meson Decay and the (J. Leite Lopes), 866
Theory of Numbers : A Chapter in the (Prof. L. J. Mordell), *review* by H. T. H. P., 315
Therapeutics : Pharmacology and (Prof. Arthur R. Cushny), thirteenth edition thoroughly revised by Prof. Arthur Grollman and Dr. Donald Slaughter, *review* by Prof. J. H. Gaddum, 887
Thermal Decomposition of Organic Nitrates (L. Phillips), 753
Thermal Hardening of Cadmium Crystals (Dr. C. L. Smith), 466
Thermionic Emission from Oxide-Coated Cathodes (Electronics Group of the Institute of Physics summer meeting on), 725
Thermionic Properties of Thoria (D. A. Wright), 129
Thermionic Valves : A Unified Theory of Spontaneous Electrical Fluctuations in (Dr. R. Fürth), 832
Thermo-nuclear Reactions under Terrestrial Conditions (Dr. J. H. J. Poole), 635
Thermochor : The, a New Additive and Constitutive Property (Hervasio G. de Carvalho), 370
Thermodynamic Test for the Internal Consistency of Experimental Data on Volatility Ratios (Dr. E. F. G. Herington), 610
Thermodynamics : Time and (A. R. Ubbelohde), *review* by Dr. J. A. V. Butler, 72
Thermodynamics and Humanism, *review* by Dr. J. A. V. Butler, 72
Thiamine of Milled Raw and Parboiled Rice (Dr. Lucius Nicholls), 298
Thiohydantoins (3 : 5-Disubstituted) : Reported Preparation of Mercapto-imidazole Derivatives by Methylation of (Dr. R. E. Stuckey), 189
Thionyl Chloride and Hydroxy Compounds : Interaction of (D. Libermann), 903
Thiosulphate on Plants : Selective Toxic Action of (Dr. L. J. Audus and Prof. J. H. Quastel), 263
Thiourea on the Endostyle of Ammocœtes : Effect of (Miss R. P. Jones), 638
Third-Order Elastic Coefficients of Crystals (Prof. S. Bhagavantam and D. Suryanarayana), 750
Thoria : Thermionic Properties of (D. A. Wright), 129
Thorium X Salts : Escape of Thoron from (Dr. F. Behounek and J. Klumpar), 640
Thoron from Thorium X Salts : Escape of (Dr. F. Behounek and J. Klumpar), 640
Thread' : The 'Floating, a Surface Phenomenon on Flowing Water (I. Kuščer), 673
Thrips in the Laboratory : Technique for Rearing (Dr. E. McC. Callan), 432
l- and *dl*-Thyroxine : Relative Activities of (W. E. Griesbach, T. H. Kennedy and H. D. Purves), 192
Tiahuanaco Ruins : Built Before the Flood, the Problem of the (H. S. Bellamy), revised edition, *review* by G. H. S. Bushnell, 852
Tick in African Houses : Economic Control of the Relapsing Fever (W. F. Jepson), 874
Tilden Lecture of the Chemical Society (Prof. E. G. Cox), 428
Tillage Land : Survey of Mineral Deficiencies on (Dr. William Plant), 336
Timber Conference : International (Report of the Food and Agricultural Organisation of the United Nations on the), 878
Time and Thermodynamics (A. R. Ubbelohde), *review* by Dr. J. A. V. Butler, 72
Times of Arrival of Bursts of Solar Noise on Different Radio Frequencies : Relative (Ruby Payne-Scott, D. E. Yabsley and J. G. Bolton), 256
Tinned Foods and Bread : Milk, (Royal Sanitary Institute, Food and Nutrition Section, and the Society of Chemical Industry, Food Group, joint meeting on), 307
Tissue Cultures of Embryonic Chicken Brain : Cultivation of the Erythrocytic Form of *Plasmodium gallinaceum* in (Herta Meyer), 155
Tissue Damage : β-Glucuronidase and (Lynda M. H. Kerr and Dr. G. A. Levvy), 463
Tissue Proliferation : β-Glucuronidase and (Lynda M. H. Kerr, Dr. G. A. Levvy and J. G. Campbell), 572
Tissues of High- and Low-Breast-Cancer Strains of Mice : Electron Microscope Studies of Normal and Malignant (Prof. R. D. Passey, Dr. L. Dmochowski, Prof. W. T. Astbury and Dr. R. Reed), 565
Titanates : Dielectric Residual Effects in (Prof. J. R. Partington, G. V. Planer and I. I. Boswell), 877
Titanium Chloride : Low-Temperature Polymerization of Isobutene by (Dr. P. H. Plesch), 868
Titanium Metal : Smears of (Dr. W. A. Wooster and G. L. Macdonald), 260
Toluene and Xylenes : The C—H Bond Energy in (Dr. M. Szwarc), 403
Tones : Combination (H. G. Yates and R. Catherall), 198
Tool in Chemistry and Technology : X-Ray Analysis as a, *review* by Dr. M. F. Perutz, 208
Toxic Action of Thiosulphate on Plants : Selective (Dr. L. J. Audus and Prof. J. H. Quastel), 263
Toxic Effects of Amino-Acids and Amines on Seedling Growth (Dr. L. J. Audus and Prof. J. H. Quastel), 222
Toxic Properties of ω-Fluorocarboxylic Acids and Derivatives (Dr. B. C. Saunders), 179
Toxicity of 'Gammexane' for Insects : Inhibition of the (J. M. Thorp and Dr. Botha De Meillon), 264
Toxicology : Research on, 634
Trace Elements in Plant Physiology : Role of (International Union of Biological Sciences symposium on), 564
Tracer Studies (Radioactive) : Application of Filter Paper Partition Chromatography to (Dr. R. M. Fink, Dr. C. E. Dent and K. Fink), 801
Tracheids and Wood Fibres : Organisation of the Cell Walls of (A. B. Wardrop and Dr. R. D. Preston), 911
Tracks of Slow Mesons in Photographic Emulsions : Observations on the (C. M. G. Lattes, Dr. G. P. S. Occhialini and Dr. C. F. Powell), 453, 486
Trade Wastes from Food Industries : Pollution by (Dr. B. A. Southgate and Dr. S. H. Jenkins), 200
Training of Laboratory Technicians : Education and, 635
Training for Management, 69
Training of Professional Electrical Engineers : The Practical (Institution of Electrical Engineers), 585
Transamination between Glutamic Acid and Pyruvic Acid : Optimum *p*H and Temperature, and Energy of Activation of the (S. Darling), 838
Transamination Process : Computation of the Free Energy of α-Ketoglutarate and Pyruvate from Constants of the (S. Darling), 403
Transfer of Salt across the Frog Skin : Influence of Adenohypophysectomy on the (C. Barker Jørgensen), 872
Transformation of Trichromatic Distribution Curves (A. Marriage), 197
Transient Reception and the Degree of Resonance of the Human Ear (Dr. R. J. Pumphrey and T. Gold), 124
Travelling-Wave Linear Accelerator for Electrons (D. W. Fry, R. B. R.-S. Harvie, L. B. Mullett and W. Walkinshaw), 351
Trees : British Forest, *review* by Prof. H. G. Champion, 106
Trees as Fodder : The Use and Misuse of Shrubs and (Imperial Agricultural Bureaux Joint Publication No. 10), 862
Trichromatic Distribution Curves : Transformation of (A. Marriage), 197
Tri-colour (Mosaic) Shorthorn Cow : A (I. Chester Jones), 337
Tridacna squamosa Lam. and *Hippopus hippopus* (Linn.) : On the Structure of the Shells and Pearls of (Dr. A. Reyne), 653
Trinidad into Mauritius : Introduction of a Beetle from, to Control *l'herbe Conde* (*Cordia macrostachya*), (Dr. S. Maulik), 194
Triphenylethylene Derivatives : Highly Active (Dr. Wadie Tadros and Dr. J. M. Robson), 20
Trithioaldehydes : The Isomeric (Dr. G. M. Bennett), 502
Trochoidal Electronic Motion : Valve with (Prof. H. Alfvén and H. Romanus), 614
Trombicula acuscutellaris Walch : Rearing of (Dr. S. H. Jayewickreme and W. J. Niles), 578
Trout : Carotenoid Pigmentation of (D. M. Steven), 540
Trout (Brown) : Astacene in the (D. M. Steven), 507

Trypanosomiasis in South Africa : D.D.T. and the Aeroplane in the Control of the Tsetse Fly and (Dr. P. J. du Toit), 485
Tryptophane : A Fluorescent Reaction of (Dr. J. V. Koštir), 266
Tryptophane as Precursor of Nicotinamide in Mammals (Dr. P. Ellinger and M. M. Abdel Kader), 675
Tsetse Fly and Trypanosomiasis in South Africa : D.D.T. and the Aeroplane in the Control of the (Dr. P. J. du Toit), 485
Tubercle Bacillus (the Vole Acid-Fast Bacillus) : The Murine Type of (Dr. A. Q. Wells), 687
Tuberculosis (Experimental) : Gonads and (Prof. R. A. Izzo and V. H. Cicardo), 155
Tuberculosis of Voles and Shrews (Dr. G. Lapage), 687
Tuberculostatic Activity of 5-Amino-2-butoxypyridine : Antagonistic Effect by certain Growth-Stimulants of the (H. S. Forrest, Dr. P. D'Arcy Hart and Dr. James Walker), 94
Tubular Charge of Explosive : Velocity of Detonation of a (D. W. Woodhead), 644
Tungsten : A New Isotope of (Dr. G. Wilkinson), 864
Turbulent Flow in Alluvium (Gerald Lacey), 61
  Effect of Charge in (Sir Claude Inglis), 60
Two-Standard Colorimentry : An Improved Biuret Reaction of Proteins and the (Dr. A. Sols), 89
Typhus : Chemotherapeutic and other Studies of (M. van den Ende, C. H. Stuart-Harris, F. Fulton and J. S. F. Niven, with C. H. Andrewes, A. M. Begg, W. J. Elford, M. H. Gleeson White, W. L. Hawley, K. C. Mills, F. Hamilton and C. C. Thomas), 726
Typhus Research (Dr. G. Lapage), 726

UGANDA : A Development Plan for (Dr. E. B. Worthington), 172 ; *review* by Prof. Walter Fitzgerald, 691
Ultrasonic Absorption in Liquids—Results for Water : A Pulse Method for the Measurement of (J. M. M. Pinkerton), 128
Ultrasonic Waves in Liquids : Absorption of (Acoustics Group of the Physical Society discussion on), 913
Ultra-Violet : Christiansen Filters for (R. L. Sinsheimer and Prof. J. R. Loufbourow), 674
Ultra-Violet Light : Marking Mosquitoes with Fluorescent Compounds and Watching them by (Dr. Rajindar Pal), 298
Ultra-Violet Region : Temperature Coefficient of Rotation of Quartz in the (A. W. Crook and Prof. A. M. Taylor), 396
Ultrafiltration Analysis, *review* by Dr. W. J. Elford, 313
Umbilical Blood : Determination of Bilirubin in the, as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn (Dr. A. Sadowski, Y. M. Bromberg and A. Brzezinski), 192
Underground Observations of Penetrating Cosmic Ray Showers (Dr. E. P. George and A. C. Jason), 327
Unified Theory of Spontaneous Electrical Fluctuations in Thermionic Valves (Dr. R. Fürth), 832
Unimolecular Reactions : Absolute Values of the Rates of (Dr. H. Pelzer), 576 ; (N. B. Slater), 576
Union of Mathematics and Physics, *review*, 139
Unit for Solar Radiation Work (Loyal B. Aldrich, Dr. Harry Wexley, Sigmund Fritz, I. F. Hand, Arnold Court and William P. Millen), 327
United States : Television in the, 118
  Vocational Education in the, 326
United States of America : The Pharmacopœia of the (the United States Pharmacopœia), thirteenth revision, *review* by Prof. J. H. Gaddum, 449
United States (South-Eastern) : Indians of the (John R. Swanton), 898
United States Pharmacopœia : The, *review* by Prof. J. H. Gaddum, 449
Universal Constants in Blackett's Formula (H. Y. Tzu), 746
Universities (British) : Students in, 861
Universities of the Empire : Congress of the, 51
Universities of Great Britain (Prof. R. C. McLean), 522
University City : York as a, 218
University Expansion in Great Britain, 769
University Teaching in Agriculture and Horticulture, 151
Unstable Elementary Particles : Evidence for the Existence of New (Dr. G. D. Rochester and Dr. C. C. Butler), 855
Unsymmetrical Dicarboxylic Acids : Relationship between the Dissociation Constants of (Dr. D. H. R. Barton), 752
Uptake of Water by Collagen in Solutions of Alkalis and Strong and Weak Organic Bases (Dr. J. H. Bowes and R. H. Kenten), 827
Upward Streamers in Lightning Discharges : Occurrence of (R. H. Golde), 395
U^{239} and Np^{239} : β- and γ-Radiation from (Prof. Hilding Slätis), 579
  Radiations from (Prof. N. Feather), 749
Uranium Hydride : Formation of (Dr. J. Guéron and Dr. L. Yaffe), 575
Uranium X : Evidence against Spontaneous Emission of Neutrons by (Dr. Hl. de Vries and H. Groendijk), 435
Uranous Sulphate with Rare-Earth Double Sulphates : Coprecipitation of (Dr. A. W. Wylie), 830
Uranyl and Lead Ions : Adsorption Isotherm of a Photographic Emulsion for (Dr. E. Broda), 231
Urceolarian Epizoites of Flatworms (Dr. T. B. Reynoldson), 265
Urea : Response of New-born Children to Hypertonic Solutions of Sodium Chloride and of (R. F. A. Dean and Prof. R. A. McCance), 904
Urinary Excretion of Phosphate with $^{32}_{15}P$ as Indicator (Dr. J. Govaerts), 53
Urine : Methionine in (Edward G. Tomich), 604
  Pteroylglutamic Acid in Liver Extracts and (Dr. L. Golberg, Dr. B. De Meillon and J. F. Murray), 22
Ursprung und von den Grenzen der Freiheit : Vom (Gustav Bally), *review*, 315
U.S.S.R. : Livestock Improvement in, *review* by John Hammond, 209
  Science in the, 636

VACUUM : High (National Research Corporation and the American Chemical Society, Division of Industrial and Engineering Chemistry, symposium on), 220
Values : Absolute, of the Rates of Unimolecular Reactions (Dr. H. Pelzer), 576 ; (N. B. Slater), 576
Valve with Trochoidal Electronic Motion (Prof. H. Alfvén and H. Romanus), 614
Variable (Complex) : Functions of a (Prof. Thomas M. Macrobert), third edition, *review* by J. H. Pearce, 626
Variable Phase-Contrast System for Microscopy : A (E. Wilfred Taylor and B. O. Payne), 338
Variables (Real) : The Theory of Functions of (Prof. Lawrence M. Graves), *review* by T. M. M. 592
Variance : Technique of the Analysis of (Dr. S. Vajda), 27 ; (Dr. F. Yates), 472
Variation in Length of Day upon the Breeding Season in Sheep : Influence of (N. T. M. Yeates), 429
Vascular Plants : New Divisions of (Dr. I. V. Newman), 836
Vegetable Cultivation in Hong Kong (G. A. C. Herklots), *review* by Dr. John Grainger, 658
Vegetable Culture : Fruit and, 881
Vegetable and Animal Origin : Crude Drugs and other Raw Materials of, *review* by Dr. W. O. Howarth, 4
Vegetation Growth in Northern Finland during 1890–1939 : Climatic Fluctuations and (Dr. I. Hustich), 478 ; (E. W. Jones), 479
Velocity of Detonation of a Tubular Charge of Explosive (D. W. Woodhead), 644
Vertebrate Anatomy : Atlas of Outline Drawings for (Prof. Samuel Eddy, Prof. Clarence P. Oliver and Asst. Prof. John P. Turner), *review* by Dr. W. S. Bullough, 813
Vertebrates (Lower) : Hermaphroditism in the (Dr. W. S. Bullough), 9
Verticillium and some other Genera of the Hyphomycete Fungi : Passive Movements of Newly Formed Acrogenous Spores in (C. J. La Touche), 679
Vessel (Naval) : Gas-Turbine Propulsion in a (Metropolitan-Vickers Electrical Co., Ltd.), 392

CENTRALIZED PLANNING AND THE HUMAN FACTOR

THE lectures on "Central Planning and Control in War and Peace", which were delivered by Sir Oliver Franks at the London School of Economics and Political Science during February and March and have since been published*, are a notable contribution to the discussion of forms of government required to serve our post-war needs. The outcome of the war-time experience of a philosopher who proved himself a successful administrator in the Ministry of Supply, they bear closely on the issues involved in numerous questions of current debate. Sir Oliver indeed limits himself to one topic, which he chose because of its fundamental importance in relation to the general pattern of economic activities in Britain during the coming decade; but much of what he has written is as relevant to discussions in other fields, such as the use of the scientific resources of Britain, and the numerous issues in town and country planning which have led to recent controversies.

The whole question of central planning and control is in fact controversial, and Sir Oliver recognizes that the application of central planning and control in peace must alter traditional conceptions and methods so extensively as to change the whole framework of economic activity. Central planning and control in peace are likely to be just as disturbing to the thoughts and habits of Governments dealing with business as to business itself. Whether such planning and control of the economic life of Britain is inevitable in the next decade is far too serious a question to be settled without deliberate and reflective discussion.

Sir Oliver draws on his war-time experience for his contribution to the discussion, and his reflexions lead him to conclude that some form of central planning and control is inevitable, and that the issue is not one which may be decided one way or the other according to the general political views of the party from which the Government is formed. This does not mean that the vast fabric of control organisations created during the War has to be re-created in peace, or that control in detail over so wide a field will be necessary. It is a question, too, which affects equally both private and public enterprise; but does not raise any issue between them or advocate a doctrine of nationalization. But it does mean that, so far as matters of principle are concerned, the subject should be withdrawn from political controversy.

This conclusion is based on consideration of military security, of the fear of unemployment and of the general condition of the world, all of which, conjoined with the special relation in which foreign trade stands to the British economy, suggest that no Government in the foreseeable future is likely to dare to do without export programmes and import programmes centrally planned and controlled. That is the position reached in the first lecture; but there is much more in the lecture. In his survey of the activities of the raw materials organisation of the Government to illustrate the way central planning and control worked in a particular field, Sir Oliver makes clear some most important points.

---

* Central Planning in War and Peace: Three Lectures delivered at the London School of Economics and Political Science on the invitation of the Senate of the University of London. By Sir Oliver Franks. Pp. 61. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1947.) 2*s.* 6*d.*

This type of central planning only works if those who are involved in the decision feel bound by it and are convinced by rational considerations that what is proposed is as fair and reasonable as can be in the circumstances. A general plan or allocation is a practical directive for ensuing action, and it is necessary that the principal agents should acknowledge a commitment to the decision. Again, after planning comes the problem of control. Here the first function is verification of fact, and the second to ensure enactment; and what Sir Oliver brings out is the flexible character of the organisation built up for such purposes during the War.

Now if Sir Oliver is right in his conclusion that some form of central planning and control must in future characterize British economy, much that is done in the transitional years could be a constructive preparation for the longer years of peace. The essence of planning and control by the State in relation to productive industry and commercial activity is the same in war and in peace: decisions of policy quantitatively expressed in the form of programmes and such measures as in particular circumstances are necessary to ensure the performance of these programmes. Such planning and control, in fact, are normal characteristics of all practical activity that is in any way reflective, and in the field discussed by Sir Oliver the decisions which the State takes on its own responsibility and initiative are industrial and commercial decisions, and diminish the field in which business can display the same qualities by providing a framework of policies within which other similar but less general decisions must be made.

It is for this reason that what Sir Oliver has to say in his second lecture on the weaknesses of really large-scale organisation is important. Such weaknesses could scarcely have been explained better; the Civil Service has no monopoly of bureaucracy. The dangers of woolliness and inflexibility and inertia are admirably set forth, and special stress is laid upon the importance of effective communication and of foresight. Here again Sir Oliver draws on our war-time experience to find some clues to the principles upon which central planning and control could be organised in peace to have a reasonable prospect of success in the economic field.

The first and essential problem is that of purpose; and the main difficulty in central planning in peace is that of finding a common purpose understood and accepted by the nation and compelling support as the common objective. That involves much intelligent work in what may be described as the field of public relations; but it also involves much on the Government side that at present appears to be commonly disregarded. Central planning means, for example, that it is no longer possible for a Government to have a number of policies each of which can be pursued independently of the others. Housing, social security, exports, education, and defence are all factors in the general plan; the extent to which resources can be devoted to each is determined when the general balance is struck. It is also the Government's responsibility to create the necessary unity of purpose by the deliberate application of human intelligence and will.

There are other implications. Adoption of central planning and control in peace commits the Government to selecting and defining the ends of the national economy as an essential part of its planning and controlling activities. It engages the Government to a radical re-definition of its function in the economic field and to the shaping of situations before they arise. All this demands a real revolution in traditional habits of thought and makes a heavy call on leadership; and Sir Oliver makes it clear that reasonable success depends on the diffusion of initiative throughout the organisation and not on the Government side only. The Government, it is true, must take the general decisions involved in the programmes, but these should be kept as few as possible.

If initiative is to be diffused, clear and understood division of function is also essential. There must be no doubt where Government leaves off and business begins, and allocation of responsibility must follow. Exercise of initiative requires not only a job to do but also knowledge of responsibility for it. Responsibility for different functions must be placed, without equivocation and without strings, on those who perform them; and not the least valuable part of this admirable lecture is the way in which Sir Oliver drives home the implications. Beyond doubt he points the way to the establishment of that mutual confidence and understanding between industry and business and Government, whether Ministers or Civil servants, which are at the very root of effective planning and control.

The stress which Sir Oliver lays here on precision of thought and definition of responsibility, if the inherent woolliness of bureaucracy is to be overcome and the temptation resisted to avoid mistakes rather than to seize opportunities, makes a pertinent comment on current affairs. No less important, however, are his observations on what is involved in this method of agreement, which as he truly says is that of democratic procedure, reconciling equality of status with difference of function. It means that the Government must refrain from treating industry and commerce as instruments of its policy, and regard them instead as equal partners in the national enterprise with different but complementary functions. Agreement, moreover, is only possible when each party understands the mind of the other and full explanations are given of what is proposed, and there is free discussion on the basis of full information.

It would be idle to pretend that there at present exists either the full confidence in which such discussion and partnership can be fruitful or the balance of policies on the Government side which is essential to central planning. In his concluding lecture, however, Sir Oliver discusses the practical possibilities of achieving such a solution as he suggests, and the advantages which Great Britain has derived from its war-time experience and which, if used intelligently, could ease the transition. Chief among these he puts the more extensive and detailed knowledge of industry and commerce which the Government now possesses, the contacts between the Civil Service and industrialists, the experience which Government departments have gained in the methods and techniques needed for central planning. Moreover, many of the younger men who have returned to business life with a knowledge of the Civil Service from inside are now missing the satisfaction of doing a job which is related in a direct and intelligible way to the national need.

This question of incentive is more important than is yet generally realized, and Sir Oliver Franks is profoundly right in suggesting that for the future of Britain it would be a good thing to add to the dignity of work. He writes pertinently also on that vital factor, the co-ordination of Ministerial action, and leans to the idea of a Minister without departmental responsibilities as chairman of a committee of the Ministries concerned. Equally his own experience lends weight to Sir Oliver's comments on the functions of Civil servants in central planning, and his suggestions that it should be a first concern of the Civil Service to increase the number of experts at its disposal who are qualified both by training and knowledge of the world for the forecasting and estimating on which programmes must be framed and decisions based, and his reminder that right decisions and sound judgment depend on a fresh mind with some degree of leisure, are timely. The tendency to overload both Ministers and departments is probably the most serious consequence of the present tempo of the Government's programme, and may well be one of the hindrances to securing much freer and more spontaneous interdepartmental co-operation.

Sir Oliver is sceptical as to the value of an economic general staff, and suggests rather that the Government should encourage the formation of groups of industrialists and businessmen, strengthened by the inclusion of an academic economist and a trade union leader, with a Civil servant as chairman and terms of reference supplied by the Government. Such groups could do something to lessen the burden which planning imposes on the Civil Service, and the appointment of special assistants relieved of administrative departmental duties and free to think and plan might also lighten the burden of permanent secretaries and their deputies, if such assistants can work effectively with the main organisation.

These suggestions admittedly only touch the fringe of the difficulty, but to lighten the strain on senior Civil servants is one of the most urgent problems if central planning is adopted; and it is not the less imperative because of the responsibility which will also rest on the Civil Service for bringing industry and commerce effectively into the formation as well as the execution of plans. It is true that a new outlook on the part of industry and commerce will be required, and no matter how clearly the problem of communication is handled from the Government side a large responsibility must fall on the trade associations. Such bodies must be prepared to forward the initiative of their members within the general plans of the Government, and they must be much more concerned with the calibre of their representatives.

Nothing in these lectures encourages facile optimism as to the elaboration of the necessary organisation for planning. The stress is indeed on the human aspect and the time factor which must be allowed if we are to arrive at the sense of the meeting and collaboration which lies at the root of the democratic method.

These organic and human aspects of government are, indeed, the critical factors in any system which is to preserve the essential freedoms and the great intellectual and cultural traditions of civilization in any sphere of life, and not the less so in that the agenda of government is increasingly concerned with scientific and technical matters. Sir Oliver makes it abundantly clear that scientific method has much to contribute to the task of government, although he does not bring out so clearly as Sir Ernest Barker has done how much the method of democracy has in common with the procedure of science itself. The controversies over the Bankside Power Station and military training areas, or the development of a university policy or the most effective utilization of the nation's scientific resources in materials or man-power must indeed be resolved in part at least on a basis of fact, for the determination of which the method of science is required. But they also demand consideration of the human and social factors, if there is to be laid bare the common interest which will call forth the loyalty and the voluntary co-operation on which democratic planning depends for its success.

Sir Oliver Franks does not take us very far in his discussion as to how this is to be achieved. Prof. K. C. Wheare recently reminded us of the potential value of advisory bodies, and Sir Oliver's proposal for the formation of groups recalls some of the proposals for constitutional reform issued by a group of the Conservative Party last year. These proposals also included drawing on war-time experience to build up a system of sub-committees designed to secure the co-operation of able men from industry and trade and organised labour and to provide Government with something in the nature of an informal economic advisory staff, in addition to the existing Economic and Statistical Sections of the Cabinet Secretariat. Here, too, the emphasis is laid on quality rather than on the representation of interests, and the ultimate test of democratic planning will come just at this point of its capacity to develop the sense of the common interest which will secure the consent and co-operation of the Government.

That is brought out as soon as we examine in detail any problem of practical planning, whether in such diverse fields as the utilization of land, power and hydro-electric schemes or the expansion of the universities. There must indeed be some adequate and efficient administrative organisation, with resources and authority to execute the policy decided. But the means by which that policy is decided is the all-important factor in a democracy. It must include not merely the fact-finding facilities, but with them a technique and system of discussion which will assist in the formation of a public opinion and a general sense of common interest ensuring agreement and support for what is decided. In these lectures Sir Oliver Franks has set forth very faithfully some of the grave dangers inherent in any bureaucracy, no matter how great its merits. But while he reminds us of the importance of efficient organisation and respect for proved principles, he does not fail to point out that the man is more important than the machine. Whether our post-war organisation of Government proves equal to the immense tasks confronting it does not depend primarily upon the wisdom of our planning in the technical sense. It depends largely upon the men and women to whom the execution of those plans is entrusted. Nor is it simply a matter of their personal integrity, administrative ability and scientific and technical knowledge. It is a question of their physical ability to meet the strain. That, in turn, depends in part only on their numbers. Above all, success depends on whether in the preparation of plans and the formulation of policy the right steps have been taken to secure the approval and co-operation of the general body of citizens whose interests are to be served.

ECOLOGY OF NORWAY

Sikilsdalen og Norges fjellbeiter

En plantesosiologisk monografi. Av Rolf Nordhagen. (Bergens Museums, Skrifter Nr. 22.) Pp. xvi+607. (Bergen: A/s John Griegs Boktryckkeri, 1943.) 30 kr.

LOVERS of Norway, plant geographers, ecologists and systematists in many countries have cause for gratitude that Prof. Nordhagen's monumental study of Norwegian mountain vegetation in general and of Sikilsdal in particular was successfully published in 1943 in spite of enemy occupation of the country. The book is the culmination of twenty years indefatigable pioneer work, and the only cause for regret is that its weight and quarto size preclude its being carried in the pocket by a visitor. In every botanical library it should, however, find a place.

As explained by the author, the work is primarily a review of the ordinary mountain vegetation of Norway, exceptional areas, no matter how interesting, being on this occasion left aside. The vegetation is prevailingly that of non-calcareous or poorly calcareous districts with Sikilsdal as the fixed starting point. From the practical point of view it is the region of mountain pasture for horses, cattle or (formerly) reindeer, and the instruction of the potential user is constantly borne in mind in the presentation of the scientific descriptions. Indeed, some of the illuminating details intended for the guidance of the practical man are not the least interesting of the contents, the botanical criteria for the detection of late-lying snow pockets (of importance to a railway engineer) being a case in point.

Prof. Nordhagen's aim has been to reduce the bewildering details of his country's vegetational types into a manageable system of recognizable units, defined in such a way that comparison with other countries, notably Sweden, Finland and Central Europe, can be carried out, and by doing so to introduce into Norwegian science a standardized ecological language. This, and not the political vicissitudes prevailing at the time of publication, is the reason why the work is written in Norwegian rather than in some other language of perhaps wider currency; and quarrel with this decision cannot be made, for it will certainly strengthen considerably the further prosecution of ecological research in the author's own country. The non-Scandinavian reader need not, however, be unduly disturbed. The basic ecological classification was published in a preliminary form in German in 1936, and the book itself is very well supplied with indexes, table of contents, diagrams, tables and illustrations from which much information can be gleaned with little need of a dictionary.

The main climatic divisions utilized are first the separation of alpine from subalpine, the latter characterized by birch wood, and secondly, the subdivision of the treeless alpine zone into three regions, the low, middle and high alpine, the last being unrepresented in Sikilsdal. Within these zones the vegetational units are grouped under the following main heads, each containing several subdivisions: dwarf-shrub heath, dry grass heath, the vegetation of the sites of late-lying snow, tall herbaceous mountain vegetation, mountain meadow and grass pasture, nitrophilous weed vegetation near hutments, the vegetation of springs and of open water, grass moors, ericaceous moors, vegetation of unstable ground (screes, etc.), vegetation of precipices. In many cases, for example, in the masterly treatment of the complexities of grass moors, the classification is put forward as provisional, but even in such cases enough is known from the work of other writers to suggest that the units put forward have a validity and usefulness not merely for Norway but also for other northern countries.

It is impossible in a review to quote in any detail the scientific content of a work as richly filled as this. To a British botanist not the least of its value is the light that it can throw on many obscure features of the vegetation of our own islands. Peculiar and rare species, *Scheuchzeria palustris, Betula nana, Salix lanata, Phyllodoce cœrulea, Athyrium alpestre,* to quote a few at random, too uncommon with us to be adequately studied, fall into an intelligible place as relicts of a former age, in the light of Prof. Nordhagen's remarks. Indeed, it may be said with confidence that this description of Norway is likely to contribute more to an understanding of the general ecology of Scotland than has accrued from work done in that country for many years past.

I. MANTON

CRUDE DRUGS AND OTHER RAW MATERIALS OF VEGETABLE AND ANIMAL ORIGIN

Textbook of Pharmacognosy

By Dr. T. E. Wallis. Pp. ix + 504. (London: J. and A. Churchill, Ltd., 1946.) 28*s*.

ONE would naturally expect a high standard of attainment from the specialists who are responsible for the teaching of pharmaceutical subjects in the College of the Pharmaceutical Society of Great Britain. By virtue of its connexion with a body in which is vested the authority to grant diplomas for the practice of the craft of the pharmacist, it is right that the College should give a lead to those institutions concerned with instructing men and women for this profession. It is pleasing to see, therefore, that Dr. T. E. Wallis has produced a volume which maintains this tradition as regards pharmacognosy, following as he does the example of the late Prof. H. G. Greenish.

It is interesting to trace the development of this subject, during the past five decades, under these two men, both of whom have had a large share in establishing pharmacognosy in Great Britain on firm foundations as an important applied science. Dr. Wallis's influence is particularly seen in the appropriate monographs on drugs in the British Pharmacopœia and the British Pharmaceutical Codex. Greenish first published his "Introduction to the Study of Materia Medica" in 1899. The sixth and last edition, entitled "A Text-Book in Pharmacognosy", appeared in 1933 and embodied the changes in the revised British Pharmacopœia of 1932. This was the standard text-book in Great Britain over this period. Meanwhile Dr. Wallis, who had become more directly responsible for the teaching of pharmacognosy at "The Square", published a "Practical Pharmacognosy" in 1925. The fourth and last edition was published in 1943. First under Greenish, then independently, Wallis has exerted considerable influence on the concept of pharmacognosy, whether for the requirements of the Pharmaceutical Society's qualifying examinations or for the training of students in this subject.

Synchronizing as it does with his retirement from active teaching, we may assume that Dr. Wallis's text-book represents his mature views on pharmacognosy. Its scope is great and varied, and yet the ground is covered with that meticulous care for correctness of detail so characteristic of the man. His wide range of knowledge of plant and animal organisms and their products is most impressive. Every aspect of the subject is thoroughly explored and presented with a wealth of illustration which makes the subject-matter both interesting and instructive. Recent research and present trends in research are included. Contributions to research by Dr. Wallis and his school have been largely in the field of quantitative microscopy, in the devising and extending of methods for estimating amounts of admixture and sophistication in powdered drugs, so as to ensure conformity to legal requirements.

Dr. Wallis's classification of the subject-matter is based upon some fundamental characteristics which bring drugs into large groups each having some particular feature in common. Morphologically similar plant organs or tissues are grouped together, such as woods, barks and galls, leaves, flowers, etc. Plant products, extracts, etc., are grouped according to their nature into gums and saccharine substances; resins, gum-resins and oleo-resins; fixed oils, fats and waxes; and so forth. For teacher and student this arrangement has distinct advantages. Discussions of general principles are deferred to the end of the book. It is doubtful if all teachers of pharmacognosy will agree with the order of arrangement of the material. It must be remembered that many students entering a course in pharmacognosy have only had training of the standard laid down by the syllabus for the Pharmaceutical Society's Intermediate Examination. The reviewer feels, therefore, that to introduce the detailed histology of woods and barks near the beginning of the book is to expect rather much from such students.

Several minor corrections will need to be made when the text-book is revised. For example, it will be noted that a number of specific names starting with capital letters in the text have small letters in the captions to figures and in the index. Thus, Figs. 124 and 125 and also the index have *Datura stramonium*, the text *D. Stramonium*. The reviewer ventures to suggest that the author also includes available stomatal index numbers along with his other criteria in his descriptions of the respective drugs.

The text-book supplies much valuable information and carries with it the authority of a careful investigator and an experienced teacher. It is to be strongly recommended to teachers, students and all who are interested, directly or indirectly. His many friends hope that Dr. Wallis, in his retirement, will long be spared to maintain his vital interest in a subject he has made peculiarly his own, and will continue to give guidance and counsel to those who may be called upon to shape its further development and progress.

The publishers are to be congratulated on a work of high merit, even though still limited by Government austerity regulations. It would have been an advantage, however, if the text-book and Wallis's companion volume, "Practical Pharmacognosy", could have been made to conform in size.

W. O. HOWARTH

FUEL PRACTICE

Fuels, Combustion and Furnaces

By Prof. John Griswold. (McGraw-Hill Chemical Engineering Series.) Pp. vii+496. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 27*s*. 6*d*.

THE reader of this book can scarcely fail to notice how technical literature has developed during the past generation. Books used by students formerly were mainly descriptive. This applied to fuel technology—a subject amenable in part to considerable quantitative physical treatment. It includes industrial operations involving chemical reactions on the largest scale and of the greatest intensity. Indeed, some of these were used by the early pioneers in their studies of thermodynamic principles. It is not surprising that in time writers found it necessary, in the interpretation of technical processes, to use modern physical chemistry. In the United States, Haslam and Russell in 1926 produced their book on "Fuels and Their Combustion", which gave to many students the first approach of this kind. Since then developments in practice have taken place, and more particularly in petroleum technology. This deals in the main with liquid materials. These lend themselves especially to physical treatment, which is reflected by several chapters in this book by Griswold. While giving an account of fuel practice, at any rate of American practice, it is sprinkled throughout with references to modern physicochemical theory. This should be advantageous to many students who find difficult the same approach by way of text-books of abstract theory. There are many who would find the grasp easier when theory is associated with industrial processes.

In conclusion, one can say that the author has realized the aim of his preface, "to satisfy the need for an up-to-date chemical engineering text in this important field. It is the first attempt since that of Haslam and Russell twenty years ago to bring together an essentially fundamental background with developments in both theory and practice."

H. J. HODSMAN

THE CHEMICAL SOCIETY

By Dr. F. SHERWOOD TAYLOR

During July 15–17 of this year the Chemical Society is celebrating its centenary, which but for the War would have taken place in 1941.

The early scientific societies extended their activities to all branches of science; it was only at the beginning of the nineteenth century that societies for the study of special branches of science began to be formed. The Astronomical, Linnean and Geological Societies belong to this period. The Chemical Society was the first national body to take chemistry as its sole object of study, for it was not until 1857 that the French Chemical Society was formed, while the Berlin Chemical Society did not originate until 1868.

In the early nineteenth century there was a considerable body of Englishmen eminent in chemistry—the names of Dalton, Davy, Wollaston, Faraday come to mind. In the eighteen-forties, however, the main activity in the science was on the Continent, where Liebig, Wöhler, Bunsen, Dumas, Gerhardt and Berzelius were at the height of their powers. The British chemists of the time were well aware of the importance of the subject, both for pure science and for industry, and the first attempts to form a society met with a warm response. The moving spirit was Robert Warington, who on February 23, 1841, convened a meeting "for the purpose of taking into consideration the formation of a Chemical Society", which was duly constituted on March 30. Thomas Graham became president; Brande, Daniell, Clark, Daubeny and Grove were among the officers. The purposes of the Society were stated in the following words: "for the advancement of Chemistry and those branches of science immediately connected with it, for the communication and discussion of discoveries and observations relating to such subjects: the formation of a Library of scientific works and of a Museum of Chemical preparations and Standard Instruments are also ulterior objects of the Society". All these intentions, excepting the last, towards which only a beginning was made, have been carried out in a manner that its founders can scarcely have anticipated.

The Society began work at once and published from time to time *Memoirs* and *Reports of the Proceedings*. Membership increased, and in 1849 a Royal Charter was obtained.

The first meetings were held in the premises of the Society of Arts; in the same year they were removed to the Westminster Literary and Scientific Institution at 47 Leicester Square; but in 1843 returned to the Society of Arts. In 1850 the Society moved to 142 Strand, then to Cavendish Square, where it occupied a part of the premises of the Polytechnic Institution. About 1853 the Government promoted a plan for accommodating the scientific societies at Kensington Gore, but this found little favour. The Burlington House site was proposed instead, but it was not until 1874 that the new buildings were ready and the Society entered upon the premises it has now occupied for nearly three-quarters of a century. In that year its fellows numbered 733; to-day they number more than seven thousand, and in view of the parallel expansion of numbers both of men and books it is not surprising that further expansion has been in question.

The "communication and discussion of discoveries", set out as the Society's first intention, has been carried out by the reading and discussion of papers, and their publication. It is impossible to estimate the value of the thousands of discussions that have taken place at its meetings, opportunities for the sharing of ideas or the no less valuable clash of opinion, which has so often had the result of leading the research worker to re-examine his conclusions, clarify his explanations and reinforce his experimental proofs. We know that much of the work that led to the adoption of the correct views concerning atomic and molecular weights was done at these meetings, and in some instances by men, such as Odling, whose published work was comparatively unimpressive. These meetings have been of especial value to junior research workers, who find in them at once a means of contact with senior workers of reputation and experience and a strong encouragement in an often ill-rewarded pursuit.

The editors of the *Journal* have likewise done much to maintain the high standard of experimental proof for which the chemists of Britain are justly esteemed. The printing of scientific papers was among the first of the Society's activities. A volume of *Proceedings* and another of *Memoirs* appeared during 1841–43; these were followed by two volumes of *Memoirs and Proceedings of the Chemical Society of London*, and between 1847 and 1864 by fourteen volumes of the *Quarterly Journal*, which contained not only original papers, but also abstracts and official reports. During 1862–71 a *Monthly Journal* was published. Space was always a difficulty, and during this period abstracts were no longer published, but in 1871 "Abstracts of Chemical Papers published in British and Foreign Journals" were included in the *Journal*. From 1878 onward the *Transactions* and *Abstracts* were separated, while from the year 1885 the *Proceedings*, which had previously been scattered through the *Journal*, were separated and form a record of the Society's business and activities. After 1914 these were published in an abbreviated form with the *Journal* and no longer contained summaries of papers. In 1924 the publication of abstracts became the province of the Bureau of Abstracts and ceased to be part of the *Journal*. Finally, in 1933 the *Journal* adopted that larger format which is familiar to-day. A most valued publication of the Society is the *Annual Reports on the Progress of Chemistry*, first published in 1905; and in the present year a new publication has commenced, namely, *Quarterly Reviews*.

Next to the reception of the publications of the Chemical Society, the most valued privilege of its fellows is the use of the library. In 1842 the secretary was empowered to obtain a bookcase. The Society received many periodicals in exchange for its own, but in 1850 the library consisted only of some 330 volumes and a hundred pamphlets. In 1855 the president, Dr. Williamson, directed the attention of fellows to the library "as a place of deposit for curious works upon chemistry". In 1860 Mr. Watts took charge of the library, and a Library Committee was first appointed in 1866. He was succeeded by Dr. L. T. Thorne in 1884, who was followed in 1894 by Mr. R. Steele. In 1903 Mr. F. W. Clifford, assistant librarian at University College, was appointed librarian, and held that office until his death in 1942. His kindly and efficient aid and his store of remarkable anecdotes will long be remembered by the present generation of British chemists. He was succeeded by Mr. A. E. Cummins, who had been assistant librarian since 1919.

By 1890 the library, exclusive of pamphlets, amounted to 9,884 volumes; during Mr. Clifford's tenure of office, it greatly expanded and became the finest chemical library in the world. The number of books to-day amounts to some 48,000, and their issue to fellows, which seems to have been customary from the first, is a most valuable service.

In 1853 it was decided to add "a little more life and general interest to the meetings by devoting up to five meetings a year to delivery of discourses on matters connected with the progress of Chemistry". A good many lectures were given, but only a small proportion of them were printed; however, as these lectures became fewer and at the same time more weighty, their publication became commoner. Five lectureships have since been founded, of which the oldest is the Faraday Lectureship, which is normally given every three years and originally had to be delivered by a 'foreigner or someone from a British Colony'. The first lecturer was Dumas; he was followed by Cannizzaro, Hofmann, Wurtz, Helmholtz and Mendeléeff. Since then, Rayleigh, Ostwald, Emil Fischer, Richards, Arrhenius, Millikan, Willstätter, Bohr, Debye, Rutherford and Langmuir have delivered the Faraday Lecture, and the eighteenth of these lectures is to be delivered on July 16 by Sir Robert Robinson on "The Development of Electrochemical Theories of the Course of Reactions of Carbon Compounds". Since 1918 four other lectureships have been founded, namely, the Hugo Müller, the Liversidge, the Pedler and the Tilden Lectureships.

The Society also gives a very practical and direct aid to research through its Research Fund, which expends an annual sum of about £7,000 in grants towards the expenses incurred by research workers.

The accomplishment of the Chemical Society is principally to be measured by the benefit that has accrued to its members' work from the amenities and facilities it has provided. We cannot estimate the intensity of this benefit, but we may form some notion of its extensiveness by considering the work that British chemists have done and are doing. A brief survey of such work must give a false impression, for it can offer no idea of the enormous volume of pieces of work, not always notable by themselves, but in the mass forming the solid structure of the science of chemistry. The principal impression that is given by a survey of British chemistry during the past century is the great increase in its volume and value after the year 1900. Not only was more work done, but also its importance relative to the work being done at the same time in other countries greatly increased. In the nineteenth century there were fine pieces of work, such as Graham's treatment of colloids, Roscoe's researches on vanadium and Perkin's syntheses of aromatic dyestuffs, but from the beginning of the twentieth century the contribution of British chemists rapidly increases. The remoter causes of this expansion are not altogether clear, but there was certainly a wave of opinion near the turn of the century which led to a more active encouragement of research at the universities of Britain, and especially at Oxford and Cambridge. Be this as it may, the facts are sufficiently impressive. Witness, for example, the discovery of the inert gases by Rayleigh, Ramsay and Travers, the elucidation of the phenomena of radioactivity by Rutherford and Soddy, the opening up of the great field of crystal chemistry by the Braggs, the epoch-making researches of Moseley. In the field of organic chemistry the electrochemical theory of the course of organic reactions is the fruit of British researches, especially those of Robinson, who has contributed so brilliantly to so many departments of organic chemistry. It would be invidious to single out one or two researches from the mass of brilliant organic work that to-day occupies the greater part of the *Journal of the Chemical Society*, but the work of present members of the Chemical Society upon the carbohydrates, the steroids, proteins, and other classes of organic compounds, is well enough known to all. The subject of chemical kinetics has been remarkably developed in Britain, in numerous centres, and is represented in the person of this year's president, Prof. C. N. Hinshelwood.

All this work has contributed to, and has been aided by, the great development of the British chemical industry, which, after a period of stagnation in the latter part of the nineteenth and early twentieth century, has been built up to a position second only to that of the United States. Never has British chemistry seen a more brilliant period than the present, and we may look forward with confidence to newer and greater conquests, both in our knowledge of things, and their utilization for the benefit of mankind.

TECHNIQUE OF X-RAY POWDER PHOTOGRAPHY[*]

By H. P. ROOKSBY

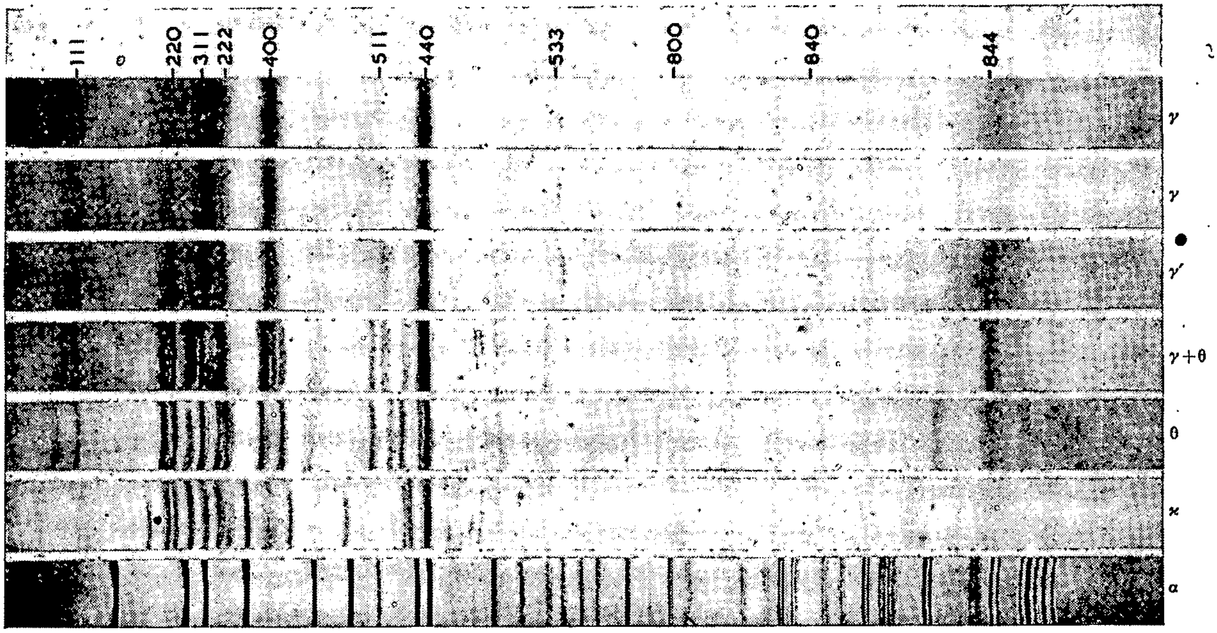
Research Laboratories of The General Electric Co., Ltd., Wembley

THE aspects of technique that influence the quality of the X-ray powder photograph can be classified into two groups: those concerned with the kind and purity of the X-radiation; and those concerned with the camera. A battery of X-ray tube target materials is desirable to give the necessary flexibility in the selection of wave-lengths. Demountable tubes in which targets are interchangeable, or sets in which sealed-off X-ray tubes containing different target elements can be quickly interchanged, provide alternative lines of approach.

In both schemes, some deterioration of the purity of the spectrum emitted by the tube has to be faced, though with the demountable set the provision of efficient evacuating equipment and regular cleaning of the target face minimize the difficulties. Nevertheless, it has to be recognized that a pure characteristic spectrum can only be maintained with certainty by the use of a crystal monochromator.

With Debye–Scherrer cameras mounted in the conventional position with respect to the X-ray tube target, line definition is primarily a function of specimen diameter and focal distance. There is a gain in resolution when the focal distance is lengthened by increasing the camera diameter. Cameras of maximum diameter of about 20 cm. have been adopted during the last few years; these are fitted with knife edges to provide reference shadows on the exposed negative. Accuracy of construction is essential to enable extrapolation methods to be applied for lattice parameter measurements[1]. Clarity of the powder photograph is improved by evacuation or hydrogen filling, and in some instances screening will help by the absorption of the secondary fluorescent radiation excited in the specimen.

[*] Abridgment of a lecture before the X-ray Analysis Group of the Institute of Physics delivered on April 22.



X-RAY POWDER PHOTOGRAPHS (COPPER *Kα* RADIATION, 19-CM. CAMERA) OF VARIOUS FORMS OF ANHYDROUS ALUMINA

A small flat crystal monochromator suitable for use with circular cameras has been described by Lipson, Riley and Nelson[2]. Bent crystal monochromators, such as have been advocated by Guinier[3] and others, have the advantage of utilizing the energy of the X-ray beam much more economically. They suffer from the disadvantages that special cameras are required, and that they are really unsuited for the line focus X-ray tube in common use in Great Britain. Increased sensitivity in analytical problems results from the use of crystal-reflected rays, because of the elimination of the white radiation component of the X-ray beam and consequent reduction of background.

One of the chief purposes for which the powdered-crystal photograph is employed in industrial applications is for the specification and identification of crystalline phases. Besides problems concerning phase diagrams in metallurgy, X-ray methods are applied to the exploration of new reacting systems in the fields of inorganic and organic chemistry. An interesting example is provided by the series of X-ray photographs distinguishing the principal phases in the alumina-water system. Not only are six or more separate constituents found, but also the transformation between the two anhydrous forms, gamma and alpha, is significant both crystallographically and practically (see accompanying illustration).

The X-ray study of iron oxides is another example, as differences in colour of iron oxide pigment preparations are known to be related primarily to changes in the crystal forms of the hydrated and anhydrous oxides[4]. The brown colour of gamma ferric oxide is markedly different from that of red hæmatite. Although the X-ray patterns of black magnetite and gamma ferric oxide are remarkably similar, that of gamma ferric oxide shows super-lattice lines as well as the displacements of the main lines associated with a smaller unit cell.

In the course of investigations of alumina/silica refractories, three forms of mullite have been distinguished by slight differences in their X-ray powder photographs[5]. The differences, which consist only of small relative displacements of high-order reflexions, are attributable to small changes in the unit cell dimensions. Some mullites of both natural and synthetic origin are found to contain up to 78 per cent of alumina compared with 72 per cent for the accepted composition with molecular formula $3Al_2O_3.2SiO_2$; yet the solid solution of the alumina effects but slight changes in the lattice parameters.

During the last few years, interest has been directed to structural anomalies or irregularities in certain substances. Powdered-crystal methods of investigation are applicable in many instances, provided the technique adopted gives sufficient clarity and resolution of the lines. In nickel oxide, for example, it has been shown that some reflexions are split into several components; there is a small distortion of the face-centred cubic structure, equivalent to a contraction along a [111] direction[6]. The nickel atom is slightly too small to allow the full cubic symmetry to be maintained.

Powder photographs of cobalt show exceptional effects, which are explained on the basis of mistakes in the stacking of the close-packed layers of cobalt ions[7]. Extra reflexions on X-ray photographs of graphite have been noted for some years[8]. They are real and not spurious lines attributable to the use of impure radiation, because they occur if the radiation is monochromatized by crystal reflexion. They cannot be accounted for by the hitherto accepted hexagonal structure, but are explained if it is assumed that in powdered graphites there is present a second closely related structure with one and a half times the cell height[9]. With most graphites, too, the X-ray powder lines show varying degrees of sharpness, attributable to imperfections in the stacking of the hexagonal nets of carbon atoms.

The significance of crystal structure in relation to physical properties such as refractive index, permittivity or piezo-electricity is becoming increasingly apparent. Polymorphic transformations with temperature such as those observed by Ubbelohde[10] and his colleagues in potassium dihydrogen phosphate and in barium titanate by Megaw[11] are examples. Although the work on potassium dihydrogen phosphate was carried out by single-crystal methods, studies of barium titanate and like compounds have been made by powdered-crystal technique. Such investigations require X-ray examinations at elevated and at sub-normal temperatures. There is obvious need for the provision of precision instruments for high- and low-temperature powder photography.

Concerning future prospects, emphasis must be placed on further developments and improvements in technique and instrumentation. Although the Geiger counter spectrometer may become extremely valuable, particularly in industrial research, the photographic film will no doubt continue to form the backbone of the powdered-crystal method for a long time to come. Much can be achieved by attention to detail and by the proper design of X-ray generators and cameras. Cameras, for example, should be such that they can be handled by any intelligent laboratory assistant, so that the X-ray crystallographer is free to devote his full energies to planning experiments and interpreting results. The work on the design of equipment being undertaken by the X-ray Analysis Group of the Institute of Physics should result in the early achievement of this ideal.

HERMAPHRODITISM IN THE LOWER VERTEBRATES

By Dr. W. S. BULLOUGH*
University of Sheffield

BY the publication in 1944 of a description of the gonads of *Monopterus javanensis* Lac. (Symbranchii; Teleostei), Liu[1] has furnished new and interesting evidence concerning the mechanism of sex determination in the lower vertebrates, and has opened a fresh field for research into this subject. It is well known that, while the separate nature of the sexes is a general rule among fishes and amphibians, there are many species in which this separation is neither stable nor complete, and a great deal of research, both descriptive and experimental, has been devoted to the problem. In these circumstances it is exceptionally interesting to find that *Monopterus* is peculiar—and so far apparently unique—among vertebrates in being a true hermaphrodite, which functions as a female during the first half of its life and as a male during the second. It appears that this discovery may be one of considerable theoretical significance, and in order to place it into its proper context, the present state of our knowledge concerning sex determination in the lower vertebrates may be briefly summarized.

Vertebrate Sex Determination

The outlines of this problem were first defined by observation and description. It has become evident that while the primordial germ cells of the male and female are strictly homologous, those which are to form ova come to lie in the cortex of the rudimentary gonad, whereas those which are to form spermatozoa come to lie in the medulla. In many fishes and amphibians, the so-called 'undifferentiated races', it has been found normal for the cortical cells to develop first, with the result that all immature individuals pass through a female stage when their gonads contain oocytes. At this time genetical males cannot be distinguished from genetical females. The phenomenon has been particularly closely studied in amphibians, and has been reviewed in detail by Witschi[2,3]. Complementary to it is the observation, made on both fishes (Bullough[4]) and amphibians (Crew)[5], that older females commonly become transformed into males. It follows that in these species the basic difference between the sexes is not absolute, but lies merely in the duration of the female stage. In the male this stage is passed in immaturity, while in the female it lasts until almost the end of life. It is further evident that animals of this type occupy an intermediate position between a typical hermaphrodite and a typical gonochorist, and that they may illustrate an important evolutionary step.

Here a caution is probably needed that such normal sex reversals as those described above must be clearly distinguished from the many abnormal cases of intersexuality which have been reported in lower vertebrates (Bullough[6]), and which are presumably due to some individual maladjustment in the mechanism of sex determination or in the endocrine balance. Further, the peculiar condition of the Mediterranean teleosts *Serranus* and *Sargus*, in which ova and spermatozoa are ripened simultaneously (van Oordt[7]), is probably to be regarded as a unique specialization of the common mechanism.

The experimental work which has been performed on the problem of sex determination has been extensive and has so far produced the following main generalizations (Witschi[2,3]). The sex, or X-, chromosomes constitute the female-determining force called F, while the rest of the chromosome complex, the autosomes, are the male-determining force called M. In some invertebrates, such as *Bonellia*, the diploid condition might be designated by the letters $MMFF$, with the strength of M being approximately equal to that of F. In these circumstances the environmental conditions determine which sex shall be dominant. In the 'undifferentiated races' of amphibians, the sexes have come to be determined by the fact that one of the female chromosomes, the Y-chromosome, has a weaker effect than the other. Its reduced strength is termed f. In these circumstances a female has the constitution $MMFF$, where F is more powerful than M; whereas a male has the constitution $MMFf$, where $M + M$ is more powerful than F + the weaker f. However, the balance is still such that it can be upset by abnormal environmental conditions, as, for example, by a high temperature. Finally, in a typical gonochorist, the state is reached where the power of the Y-chromosome is nil. A female then has the constitution $MMFF$ and a male MMF, and in these circumstances sex is relatively stable from the earliest stage of development.

---

* Sorby Research Fellow of the Royal Society.

The mode of action of these sex-determining forces is through a stimulation of inductor production within the indifferent gonad. The nature of the inductors is not yet understood, but they are known to diffuse from cell to cell and are presumed to be of a protein nature. The female inductor is called 'corticin', the male inductor is 'medullarin', and they are, of course, strongly antagonistic. It must be emphasized that they are not to be confused with the sex hormones of older animals. In the 'undifferentiated races' œstrogenic hormones can induce immature genetical males to develop into females just as androgenic hormones can induce immature genetical females to become males (Witschi[8]); but these effects would appear to be entirely artificial.

Research on the 'undifferentiated races' has also led to the further important conclusion that in these animals the chromosome balance between MM on one hand and FF or Ff on the other is not constant, but varies with age. This is the explanation of the fact that a male develops first as a female, since the influence of $F + f$ is felt before that of $M + M$. When the full power of $M + M$ is felt, the direction of development changes and the animal becomes transformed into a male. It is unfortunate that little or no experimental work has yet been done on the mechanism involved in the change of older females into males. It might be guessed that the nature of this change may be similar to that in young males, except that the sex hormones may play a significant part. Its basis may be that the relative power of $M + M$ finally rises to dominate that of $F + F$, either by an actual change in the powers of the chromosomes or by a change with age in the response of the gonads to them.

Hermaphroditism of *Monopterus*

The discovery of the condition of *Monopterus javanensis* makes the experimental study of adult sex changes even more urgently necessary, and because of the inaccessibility of the original paper, a restatement of the results already announced regarding this species may be of value. The fish itself is widespread in the rice fields of China, the Malay Archipelago, and the East Indies. It has an eel-like form, it is capable of breathing air, and it reaches a length of some 60 cm. Most of the 659 specimens on which the work is based were obtained from the market at various times throughout the year, and they were reported to have been caught in the rice fields of Pehpei and Hockwan in Swechwan, China. No secondary sexual characters can be identified in this species, and the sexes were therefore distinguished by the superficial appearance of the gonads. The intersexes were not at first recognized, and since they still possessed eggs they were classed as females. Consequently, with the accompanying table, the warning is given that the figures for females "possibly include a small number of intersexes". In this table, since age could not easily be determined, the state of the gonads is related to body-length.

The fish of the first three length-groups, referred to as fingerlings, were immature, but they were clearly recognizable as females. The next groups contained young adults which were also almost entirely female, and many of which contained fully developed eggs ready to be shed. The normal 1 : 1 sex ratio was found only in the narrow length-range of 36·0–37·9 cm. Of the 300 adult fish below this range, 270 (90 per cent) were females, while of the 210 fish above it, 185 (88 per cent) were males. It can only be concluded that all individuals commence life as females and breed as such before becoming transformed into males. In other words, "male and female in this fish are not distinct categories, but are merely temporary phases in the life of the same individual". For the greater part of the population the change in sex is accomplished between the body-lengths of 34 cm. and 40 cm., but occasional exceptions occur. Thus one specimen of only 23 cm. body-length was found to have completed a precocious change, while two others of 48 cm. and 50 cm. body-lengths respectively were still true females. These last two fish were obtained from a pond which was unusual in that it never dried up, and that it contained an abundant food supply. It is therefore suggested that such exceptions may be the result of abnormal living conditions, and particularly of abnormal nutrition.

FREQUENCY OF MALE AND FEMALE INDIVIDUALS IN DIFFERENT RANGES OF BODY-LENGTH

Class range in cm.	Male		Female		Total number
	Numbers	Percentage	Numbers	Percentage	
5·0–6·9	0	0	18	100·0	18
7·0–8·9	0	0	58	100·0	58
9·0–10·9	0	0	9	100·0	9
22·0–23·9	1	20·0	4	80·0	5
24·0–25·9	0	0	8	100·0	8
26·0–27·9	1	3·3	30	96·7	31
28·0–29·9	3	6·7	42	93·3	45
30·0–31·9	6	8·8	62	91·2	68
32·0–33·9	7	10·3	61	89·7	68
34·0–35·9	12	16·0	63	84·0	75
36·0–37·9	35	54·7	29	45·3	64
38·0–39·9	32	65·3	17	34·7	49
40·0–41·9	32	94·1	2	5·9	34
42·0–43·9	28	93·3	2	6·7	30
44·0–45·9	31	96·9	1	3·1	32
46·0–47·9	16	94·1	1	5·9	17
48·0–49·9	17	94·5	1	5·5	18
50·0–51·9	8	88·9	1	11·1	9
52·0–53·9	11	100·0	0	0	11
54·0–55·9	7	100·0	0	0	7
56·0–57·9	3	100·0	0	0	3

The histological details of the gonad transformation have not yet been closely studied by Liu; but the following short account can be given now. The ovary is bounded by a thick connective tissue tunica, from the dorsal side of which two long connective tissue folds hang into the ovary cavity. The cavity enclosed by each of these folds is empty, while the cavity between and around the two folds contains the oocytes. During the change of sex, testicular tissue arises within the walls of the connective tissue folds, and simultaneously the oocytes begin to disintegrate, the largest being affected first. By the time the testicular tissue is fully developed, the oocytes have entirely disappeared.

Conclusions

It will be evident that these observations on *Monopterus* agree well with those already made on the various 'undifferentiated races' of the lower vertebrates. In the first place, *Monopterus* shows the normal juvenile female phase, and in the second the sex-change is in the normal direction of female to male. Indeed, the only difference between it and the other fish and amphibians mentioned above is one of degree. In *Monopterus* all individuals change their sex at about the same age, while in the others half (the males) make the change early, and half (the females) make it late or not at all. However, this difference is of considerable theoretical interest, and it is important that an attempt should be made to discover whether the hermaphrodite condition of *Monopterus* is primitive or specialized.

The evidence available from the study of the various 'undifferentiated races' can be held to support a theory that some, if not all, of the members of the old vertebrate stock were protogynous hermaphrodites, and that only afterwards were separate sexes established by the evolution of a chromosome mechanism which caused a progressively earlier sex change in the forming males and a progressively later one in the forming females. Thus *Monopterus* may be to-day in a condition similar to that of the earliest vertebrates. Unfortunately for this theory, the primitive nature of any of the features of *Monopterus* cannot be lightly assumed. It belongs to an aberrant order, the Symbranchii, the affinities of which have not yet been fully settled, and it may well be that the mechanism of its sex reversal is as specialized as is its bodily structure. One test which might be applied is to search for some trace of a Y-chromosome. If the hermaphrodite condition is primitive, this chromosome may be lacking; but if it is secondary, it may still be distinguishable by its shape. It is clearly a matter of great interest that further and more detailed research should be carried out on this unusual fish, and also that a search for similar conditions should be made in the other members of the order Symbranchii.

OBITUARIES

Sir Thomas Holland, K.C.S.I., K.C.I.E., F.R.S.

With the unexpected death of Sir Thomas Henry Holland, on May 15, British geology in general and Indian geology in particular has lost its most illustrious figure, one whose outstanding position was recognized by the fact that he was president designate of the Eighteenth Session of the International Geological Congress to be held in Great Britain in 1948, and was also president of the Organising Committee of this Congress.

Thomas Henry Holland was born on November 22, 1868, at Helston, Cornwall, and was the son of John Holland, of Springfield, Manitoba, Canada, and Grace Treloar Roberts.

He was educated at a small dame's school at Helston, and when only sixteen won a National Scholarship to the Royal College of Science, London, where he took a first class associateship in geology with honours, in 1888, winning also the Murchison Medal and Prize. After a period at South Kensington as assistant to Prof. Judd, he gained a Berkeley Fellowship to Owens College, Manchester, in 1889. In 1890, at the age of twenty-one, he was appointed an assistant superintendent in the Geological Survey of India. He did not, however, proceed direct to his appointment, but travelled to India via the United States, Canada and the Far East, his service dating from his arrival in Calcutta in October 1890, when he was made curator of the Geological Museum and Laboratory. In addition, he became the part-time lecturer in geology at Presidency College, Calcutta, where (there being then no professorship in geology) he organised the courses in geology and established securely the custom that prevailed for many years by which the curator of the Geological Survey of India usually also lectured at Presidency College. While curator, Holland effected many improvements in the arrangement of the Mineral Gallery of the Museum, continuing the work begun by F. R. Mallet. In particular, he assembled and arranged typical collections of the pre-Cambrian (including Archæan) formations of India.

Although, by holding the post of curator for some years, Holland was nominally stationed at headquarters in Calcutta, he made repeated excursions into the field, and was also available to the director of the Geological Survey for emergency inquiries as they arose. He thus soon established for himself a reputation as a petrographer, and as one interested in the economic side of geology; that he was a man of energy and organising ability the Government of India soon became aware.

Throughout its history, the Geological Survey had devoted a considerable part of its energies to the mapping and study of the Indian coalfields, and had also recently had a specialist (F. H. Hatch) at work on certain gold deposits. Yet on the whole the department was then, in the view of the Government of India, giving too much attention to the theoretical side of geology and too little to the practical side. The consequence was that in February 1903 Holland was appointed director in succession to C. L. Griesbach, who was retiring on superannuation. This meant the supersession of several geologists senior to Holland, some of them (for example, R. D. Oldham, C. S. Middlemiss and T. D. La Touche) of first-class quality. After the initial shock, however, they collaborated loyally with the young new director (Oldham retiring two years later), and Holland set to work to reorganise the work of the department and to raise its status, both with Government and with the business public. He secured from the Government of India an increase of staff and better terms of pay, and detailed some of his officers to make comprehensive studies, scientific and economic, of particular minerals (for example, coal, manganese ore, and petroleum) on the lines he had already set for mica before his promotion.

In addition, Holland secured the transfer from the Revenue and Agriculture Department of the Government of India to the Geological Survey the duty of collecting and collating the statistics of mineral production of India, in annual reviews published in the *Records of the Geological Survey of India*, which he resuscitated after their suppression by his predecessor. Further, he instituted the well-known quinquennial reviews of mineral production, the first one actually covering a six-year period, 1898–1903. These quinquennial reviews are not mere assemblages of the annual figures. They contain, also, geological and economic data, covering each mineral, that are not in the annual reviews; and they were, until 1933, a special feature of the *Records* of the Indian Geological Survey that had no parallel among the publications of any other geological survey in the world.

Holland also secured the transfer to the Geological Survey of the duty of advising the Central and Provincial Governments concerning the terms of the grant of mineral concessions throughout British India, the existing rules being still based on the rules as revised by him. He was also president (1908) of the Burma Oil Reserves Committee, which drew up the rules for the regulation of the Burma oilfields with the object of preventing their wasting competitive exploitation by rival companies.

In spite of the great number of administrative improvements effected by Holland, he was director of the Geological Survey only until 1909, when he accepted an invitation to the chair of geology of the University of Manchester. One of the reasons for his early retirement from India was his disappointment that the Government of India had not implemented in full his scheme for the increase of staff and scales of pay of his department. However, Holland's outstanding services to science in India were recognized by the award of the K.C.I.E. in 1908.

It is not too much to say that as a result of Holland's directorship the Geological Survey of India was permanently faulted up, to use a geological simile, into a position of prestige in India, both with Government and with the public, from which it has never fallen back. His successor, Sir Henry Hayden, for example, quite early secured the increased cadre and scales of pay for which Holland had fought.

Sir Thomas, as he had now become, was, however, destined to return to India; in 1916 he was appointed chairman of the Indian Industrial Commission, the report of which may be taken as a basis of the Government of India's help in the modern industrial development of India. The knowledge of Indian industries obtained during its investigations led to the whole Industrial Commission being converted, also in 1916, into the Indian Munitions Board, with Holland as president; and all who had the privilege of working under Holland in this Board know the skill and energy with which he built up the giant organisation that kept the Indian armies, wherever employed, supplied with all the varied munitions and stores required for modern warfare. It is fair to say that three men, the Commander-in-Chief, the Finance Member to the Government of India, and the President of the Board of Munitions, were the principal organisers and directors of India's military effort in the First World War. For his share in this Sir Thomas was created K.C.S.I. in 1918. When the War ended, the Indian Munitions Board became, in 1919, the Department of Munitions and Industries, Holland thus becoming a member of the Viceroy's Executive Council. In 1921 he was also appointed Member for Commerce, so that he held two portfolios simultaneously. At the end of 1921 a difference with the Viceroy (Lord Reading) on the withdrawal of a munitions prosecution in Calcutta led to Holland's resignation; but the sympathies of all who knew the inner facts were with Sir Thomas Holland.

This check in Holland's career was but of brief duration. In 1922 he succeeded Sir Alfred Keogh as rector of the Imperial College of Science and Technology, London; and his success as an educational administrator in this post led to his appointment in 1929 as principal and vice-chancellor of the University of Edinburgh in succession to Sir Alfred Ewing. In spite of his dictum that seven years in one appointment was sufficient, Sir Thomas held the Edinburgh office for fifteen years, retiring in 1944 at the age of seventy-six with the title of emeritus principal and vice-chancellor of the University.

It must also be recorded that after retiring from the Geological Survey of India, Sir Thomas retained his interest in oil problems. Thus, he was a member of the Royal Commission on Navy Fuel, 1911–13. In 1928 he visited Trinidad and reported to the Colonial Office on policy in promoting the maximum and most efficient exploitation of the Island's oil resources. He was for many years geological consultant to the Burmah Oil Company and for nearly twelve years a member of the geological advisory board of the Anglo-Iranian Oil Company.

Although Holland was thus almost continuously in harness for fifty-four years, his outstanding energy and organising ability led naturally to his taking also a prominent part in the administration of scientific and technical societies and institutions. He commenced by founding in 1906 (with the late W. H. Pickering, chief inspector of mines in India) the Mining and Geological Institute of India, of which he became the first president. He was chairman of the trustees of the Indian Museum, Calcutta, 1906–9, and in 1909 he was president of the Asiatic Society of Bengal (now the Royal Asiatic Society of Bengal). In 1915–16 he was president of the Institution of Mining Engineers, London. Later, he was president of the Institution of Mining and Metallurgy, and of the Institution of Petroleum Technologists, and chairman of the Royal Society of Arts, all at the same time (1925–27). During 1927–30 Holland was chairman of the Empire Congress of Mining and Metallurgical Institutions, and in 1933–34 he was president of the Geological Society of London and in 1933–36 of the Mineralogical Society. He also served the British Association as a sectional president (geology, 1914, and education, 1926) and was president of the Association at its meeting in South Africa in 1929. He was a vice-president of the Royal Society in 1924–25.

On his retirement from Edinburgh in 1944, Sir Thomas returned to London with vigour of mind and body unimpaired, and resumed his practical interest in the administration of learned and technical societies. He rejoined the Council of the Institution of Mining and Metallurgy as a past-president, and became foreign secretary to both the Geological Society and the Mineralogical Society, his seniority and personal friendship with many geologists and mineralogists abroad making him peculiarly suitable for such work. Further, as already mentioned, he was to be president of next year's International Geological Congress.

It was inevitable that a man of such outstanding ability and energy should be the recipient of many honours in addition to the awards of K.C.I.E. and K.C.S.I. already mentioned. In addition to honorary degrees from many universities he received the Bigsby Medal of the Geological Society of London (1913), the Albert Medal (1939) of the Royal Society of Arts, and was an honorary fellow of the Royal Asiatic Society of Bengal.

Although Holland, from the time of his promotion to the directorship of the Geological Survey of India at the very early age of thirty-four, devoted his energies and abilities mainly to scientific and educational administration, yet he had already to his credit a considerable volume of first-class research, mainly on the petrographical (and chemical) side of geology; this was recognized by his election to the Royal Society in 1904. His published papers include five *Memoirs*, of which one is on the charnockite series (1900), another deals with his discovery of elæolite-syenites in India (the Sivamalai series, 1901), and a third is a comprehensive work on the mica deposits of India (1902), dealing with both the scientific and economic aspects of a mineral of which

India is the world's chief source of supply. Many of his papers in the *Records of the Geological Survey of India* also deal with petrographical problems, of which the most noteworthy are perhaps those on the mica–apatite–peridotite intrusions in the Bengal coalfields (1894) and on the origin and growth of garnets (1896). Holland also recognized early the essential identity of bauxite and laterite (*Geol. Mag.*, 1903). One of Holland's earliest papers, that on the Gohna landslip, Garhwal (*Records, Geol. Sur. India*, 27; 1894), recorded work that created a sensation with the Indian public. A landslip had thrown a dam across a Himalayan valley and created a large lake where there had been none before. Holland, who was sent to investigate, gave a middle date for the breaching of the dam and the depth to which it would be cut down when this happened. He also recommended the evacuation of the population endangered by the prospective floods some time in advance of his date. This was done, and the dam was breached on almost the exact date predicted. Holland also gave valuable advice in connexion with landslips in the hill stations of Naini Tal and Darjeeling.

The research for which Holland is best known to science is that described in his *Memoir* (28, Pt. 2; 1900) on the charnockite series, in which he described a peculiar series of granulitic rocks ranging in composition from acid to ultrabasic and forming an important part of the Archæan terrain of the Madras Presidency. The common denominator in these rocks is the presence of hypersthene; and for the type rock, a hypersthene-granite, Holland selected the name 'charnockite' after Job Charnock, the founder of Calcutta. Charnock's tomb is in St. John's Churchyard, Calcutta, and, as Holland discovered, is fashioned out of a block of hypersthene-granite brought from Madras. In Holland's view, all the members of his charnockite series are consanguineous and form a petrographic province of genetically related plutonic igneous rocks. Similar rocks have been found since in other countries, for example, Antarctica, West Africa and Uganda, and their origin has for many years been a matter of controversy. Whatever may be the final verdict on the origin of this interesting suite, there can be no doubt as to the importance of Holland's work thereon, and of the stimulus it imparted in many countries to the study of their hypersthenic rocks, and in India to that of the Archæan terrain in general.

Whatever Holland wrote, whether in official correspondence, or for publication, was precise and clear, and often trenchant. His presidential addresses to learned and technical societies never went into details, but always dealt with broad outlines, so that they were of widespread interest. In his earliest such address (that to the Mining and Geological Institute of India in 1906) he proposed a new scheme for classifying the geological formations of India, holding that the main divisions suitable for Europe, where stratigraphical nomenclature originated, were not suitable for Gondwanaland with its very different geological history. Thus came to be introduced the terms 'Aryan', 'Dravidian' and 'Purana', with Archæan at the base, for the larger subdivisions of the geological column in India. This interest in stratigraphical nomenclature caused Sir Thomas after his first retirement from India to write his "Indian Geological Terminology" (*Mem., Geol. Sur. India*, 43, Pt. 1; 1913), in which he was helped by the late Mr. G. H. Tipper (see *Nature*, June 21, p. 834), and of which a second edition appeared in 1926.

In his first address as president of the Geological Society of London (1933), Sir Thomas discussed "The Geological Age of the Glacial Horizon at the Base of the Gondwana Systems", showing that this horizon is one of the most important datum lines of the geological column. In his second address (1934) he took as his theme the ideal composition and minimum strength of a geological survey department if it was to be fully efficient. This address has been, and is likely in the future to be, of great use to directors trying to convince their Governments of the needs of their departments. In his address as president of the Geological Section of the British Association in Australia in 1914, Sir Thomas reviewed recent advances in developing theoretical conceptions regarding the interior of the earth that are of direct importance to geologists. In his address as president of the Association at Johannesburg in 1929 he discussed "The International Relationship of Minerals". Sir Thomas was greatly interested in the impact of the economics of mineral deposits upon national and international affairs, as was shown by this and other addresses, and as was summarized in a small book entitled "The Mineral Sanction as an Aid to International Security" (Oliver and Boyd, 1935), in which he showed, before the recent War, that if the British Commonwealth, the United States of America and the U.S.S.R. were to adopt a common policy on the export of minerals of use for munitions purposes to potentially aggressor countries, such as Germany and Japan, the outbreak of war could be prevented.

As will be judged from the foregoing, Sir Thomas Holland was a man of outstanding ability and energy. His worship of efficiency meant that he could not suffer fools, and that in his official relations his reactions to his colleagues and subordinates were mainly determined by his desire for efficiency, with handsome recognition of good work. But in private life Holland could be a delightful companion, especially as he was a good *raconteur* with an endless fund of amusing stories.

Holland married first, in 1896, Frances Maud (who died in June 1942), daughter of the late Charles Chapman, Deputy Commissioner in Oudh, and by this marriage he had one son (now Major-General John F. C. Holland) and one daughter (Margaretta, widow of Col. A. G. Shea); and secondly, in 1946, Helen E. Verrall, of Bramley, near Guildford.

L. L. FERMOR

Prof. F. Pavlíček

PROF. FRANTIŠEK PAVLÍČEK, who died on January 4 at the age of seventy-two, was one of Brauner's earlier pupils. Brauner and Pavlíček undertook in 1900 the revision of the atomic weight of lanthanum, and their results were eventually published in the *Transactions of the Chemical Society* in a lengthy paper. The figure they obtained, 139·04, is still accepted. Most of Pavlíček's later work was connected with mineralogy, fuel technology and thermochemistry, since he held appointments first at a technical college in Brno and later at the Příbram School of Mines in South-West Bohemia. These investigations, mostly published in Czech, relate to the calorific values of various coals (including local lignites) and the utilization of coal gas, industrial gases and coke in metallurgy. Prof. Pavlíček also wrote, in 1927 and 1931, the standard Czech work on the chemistry of coal.

J. G. F. DRUCE

NEWS and VIEWS

Chemistry in London

The Chemical Society, the centenary of which fell in 1941, is celebrating the occasion during July 15–17 (see p. 6 of this issue) by a series of meetings in London. Whereas only two overseas countries, France and Germany, sent representatives to the jubilee meetings, some twenty different countries will be represented. Among the bodies represented will be the Australian Chemical Institute, the Chemical Institute of Canada, the New Zealand Institute of Chemistry and the South African Chemical Institute. The Irish Chemical Association is sending its president, Dr. Vincent Barry. India will be represented by a distinguished delegation including Sir Shanti Bhatnagar, Sir J. C. Ghosh and Dr. Venkataraman. Other Commonwealth local representatives who will be present are Dr. T. Iredale (Australia), Prof. W. D. McFarlane (Canada), Prof. W. Pugh (South Africa) and Prof. T. S. Wheeler (Eire).

France will be represented by Prof. R. Delaby, president, and Dr. G. Champetier, secretary, of the Société Chimique de France, and by a representative of the Société de Chimie Industrielle. The Société Chimique de Belgique will send Prof. J. Timmermans. Dr. H. Jørgensen will be the official representative of the Kemisk Forening, Copenhagen, and will be accompanied by Profs. Niels Bohr, N. Bjerrum and N. J. Brønsted. Profs. G. de Hevesy and H. Erdtman will represent the Royal Swedish Academy of Sciences and the Swedish Chemical Society. Prof. E. Berner, president of the Norwegian Chemical Society, will represent Norway. Prof. D. Marotta will represent the Societa Chimica Italiana. Prof. Paul Karrer will be the official representative of the Swiss Chemical Society, and he will be accompanied by Prof. L. Ruzicka. A very strong delegation will come from the great sister organisation, the largest chemical society in the world, namely, the American Chemical Society, the official delegates of which will be the president, Dr. W. A. Noyes, jun., president-elect, Dr. C. A. Thomas, and secretary, Mr. A. H. Emery. Other Americans present will be Colonel Marston T. Bogert and Prof. Linus Pauling. China will be represented by Prof. Edith Chu.

Following on the Chemical Society celebrations, there will be the eleventh International Congress of Pure and Applied Chemistry, which is being held chiefly at the Imperial College of Science and Technology, South Kensington, during July 17–24, and concurrently, meetings of the International Union of Chemistry in the apartments of the Royal Society. Lord Leverhulme is president of the Congress, which is meeting in fourteen sections, one of them being a new one formed at the request of France to discuss chemistry in relation to essential oils, flavouring materials and cosmetics. It is expected that some two thousand chemists from at least twenty-four different countries will attend. The opening ceremony by the president of the Congress and the closing session, consisting of a lecture by Sir Robert Robinson, president of the Royal Society, will be at the Central Hall, Westminster, and all other sessions at the Imperial College of Science and Technology, South Kensington. The last International Congress of Pure and Applied Chemistry, which normally is held every four years, was in Rome in 1938; the only previous one to be held in London was in 1909. The first was in Brussels in 1894.

Chemistry in Glasgow: Opening of the Henderson Laboratory

At a short ceremony held in the Chemistry Department of the University of Glasgow on the afternoon of June 25, Sir Robert Robinson named the new Henderson Laboratory. This Laboratory had been occupied by the Admiralty during the War; and the University's share in the cost of its re-equipment to provide up-to-date accommodation for sixteen graduate research workers in organic chemistry has been partly met from a fund raised in memory of Henderson's work both at the Royal Technical College (1892–1919) and at the University (1919–37). Prof. J. W. Cook paid tribute to Henderson on behalf of the University and Prof. W. M. Cumming on behalf of the Royal Technical College. Dr. J. W. McDavid (chairman of the Explosives Division of Imperial Chemical Industries) moved a vote of thanks to Sir Robert Robinson. Sir John Boyd Orr, the newly installed chancellor of the University, was present, as was also the principal, Sir Hector Hetherington. Earlier in the day the University had conferred upon Sir Robert Robinson the honorary degree of LL.D.

Zoology at Birmingham: Prof. P. B. Medawar

Mr. P. B. Medawar, fellow of Magdalen College, University demonstrator and lecturer in the Department of Zoology and Comparative Anatomy, Oxford, has been elected to the chair of zoology in the University of Birmingham. Not yet thirty-three, he has had a brilliant career at Oxford, winning a Christopher Welch Research Scholarship in 1935, the Edward Chapman Research Prize in 1938, and the Rolleston Memorial Prize in 1942. While his outlook is physiological and experimental, he has a true regard for the discipline of comparative anatomy which will ensure that his school will be well balanced and built upon a sound foundation. It is relevant to recall what he wrote in an article on zoology at Oxford in *Biology* in 1944: "It is indeed not comparative anatomy, but the *method* of comparative anatomy, that makes the substance of Oxford's tradition of zoology. Comparative anatomy is only part of zoology, but the method devised for its analysis is the method of all creative science in its most difficult, fallible, and in a sense most sophisticated form. In comparative anatomy, the object is not to examine diverse animal forms, which is easy, but to appraise the significance of their diversity. . . . If it has ever been said that a man trained in the methods of comparative anatomy should be able to turn his hand to most things, the variety of Oxford's useful researches in zoology does nothing to belie the judgment."

Prof. Medawar himself has a great variety of zoological interests, and his research lies along two very different lines. In one he is developing the mathematical treatment of animal form and the process of growth and ageing; in this he carries forward the pioneer work of Sir D'Arcy Thompson. His second main interest is a study of the differences between individuals. Here come his valuable researches on mammalian skin grafting, so important in their human application; his approach to the problem is both immunological and genetical. A recent development has been his discovery and investigation of the curious phenomenon of an induced spread of pigmentation when pieces of black skin are grafted into white areas of a piebald guinea-pig. Prof. Medawar has a fertile imagination combined with an ability for putting his ideas for research into practice. We look forward with confidence to the development of his Birmingham school of zoology.

František Křižík (1847–1941)

ALTHOUGH he died in occupied Prague as recently as 1941, Křižík's centenary falls this year. Born of poor parents on July 8, 1847, he was as much a man of science as an engineer. His aim in life was neither riches nor fame, but he had a constant desire to invent, to improve and to lessen the drudgery of manual labour. Obviously he had to seek a career in electrical engineering, and as a youth he attracted attention by installing a satisfactory telegraph system on the various private Central European railways that were then being constructed. As a railway engineer Křižík had plenty of scope for his inventive talent, and in 1878 he introduced a block signal system designed to prevent accidents. In 1880 he produced an electric arc lamp that gave better and more constant illumination. In the following year, opportunity was taken to show the lamp at the Paris Exhibition, where it gained first prize. Gold medals were also awarded for it at the Munich and Vienna Exhibitions of 1883, and these lamps were soon being made in Britain and used for lighting the streets of London, Paris and elsewhere. Křižík now gave up his railway appointment at Pilsen and established an electro-technical works at Prague for making not only lamps, but also dynamos and other electrical apparatus and machines. He experimented with an electrically driven train as early as 1891, the year of the Prague Exhibition, for which he was both architect and engineer. His illuminated fountain and electric railway (the precursor of many European tramways) provoked wide comment and largely contributed to the success of the exhibition.

No less than a hundred and thirty electrical power stations were constructed by Křižík, who was all the time studying electro-technical theory and applying it to problems of transport, lighting and other needs. He was critical of academic instruction in physics; for in his student days at the Prague Technical University, the whole of electro-technics was dismissed in two lectures as part of the course in electricity. In his later years he was engrossed in the expansion of his works, but was certainly active and interested in the progress of science at the time of his ninetieth anniversary. He died in the midst of the Second World War on January 22, 1941, at a time when it was impossible to pay tribute to his achievements.

British Scientific Instrument Research Association: New Laboratories

THE formal opening of the new laboratories of the British Scientific Instrument Research Association will take place on Thursday, July 10 (not July 9 as previously announced). The Minister of Supply will be the principal guest. The address of the laboratories is "Sira", Southill, Elmstead Woods, Chislehurst, Kent (Imperial 2237). Recent issues of the monthly *Bulletin* of the Association have reported on the progress made in transferring the Association's laboratories from Russell Square, London, to "Sira". The Chemical Department occupies the first floor of the new buildings, with a large main laboratory, two research laboratories, a balance room, a preparation room and ample storage space. There is also a furnace room, equipped with glass-making crucibles, away from the main building. The transfer of the Physics Department was begun last December, and it will occupy two large laboratories, a dark room and an office, all situated on the ground floor. One laboratory is equipped as a high-vacuum laboratory, with three different types of evaporation plants (Hickman, Edwards and Metro-Vickers). This section has been largely concerned in the past with the problems of production of aluminium, rhodium and anti-reflexion evaporated films. Efforts are now being directed to the production of three types of interference films: uncoloured reflexion films for beam-splitting, coloured reflexion and transmission films for coloured filtering, and strongly selective transmission filters for narrow-wave-band filters (see *Nature*, **158**, 422; 1946). The second laboratory is being equipped as a General Physics Laboratory, where problems of instrument design and manufacture, such as the measurement and control of humidity, high-temperature thermocouple measurements, and the measurement of high resistance, are to be studied.

Benjamin Franklin House

ON June 27, Mrs. Lewis Douglas, wife of the American Ambassador in London, unveiled a commemorative tablet in Benjamin Franklin House, 36 Craven Street, London, W.C.2. This is the headquarters of the British Society for International Understanding, an educational organisation which was formed early in 1939 to promote among the British people a genuine understanding about other nations. It was in this house that Benjamin Franklin, one of the founders of the American Constitution, lived between 1757 and 1775 as agent for Pennsylvania, and carried out his electrical experiments, notably on the lightning conductor, and wrote much of his work. During the Second World War, the house was severely damaged by incendiary and explosive bombs. It has, however, been restored so far as possible to its original condition, with the aid of the American Philosophical Society, the Historical Society of Pennsylvania, the Franklin Institute of Philadelphia and Miss Caroline Bache, a great-great-great-granddaughter of Benjamin Franklin.

The British Society for International Understanding, as an independent, non-party organisation, relies entirely on subscriptions, donations, the sale of literature and payment for its services, the principal of which are the publications called "British Surveys". There are two types of "British Surveys". One is the main edition, intended for adult reading, and the other the popular series which are especially written for use in schools. Each survey gives accurate, unbiased background information on a particular country or an international topic. The main edition is published fortnightly and the popular series monthly. The Society also recommends lecturers and answers inquiries about foreign affairs and the British Empire. Mrs. Douglas said at the formal opening of Benjamin Franklin House that it was appropriate that his one-time home should be dedicated as the headquarters of a Society for International Understanding, for it would be hard to point to a more international figure than Benjamin Franklin. "It is Benjamin Franklin the world citizen we salute to-day. He lived in a period of collision and war, but he always stood for union and harmony and he became one of the great representatives of international culture."

Geological Society of Turkey

The Geological Society of Turkey (Türkiye Geoloji Kuruma) was officially founded in June 1946 at Ankara. The headquarters are in the Institute of Mining Research, Ankara, and the officers are: *President*, Prof. H. N. Pamir; *Vice-President*, Dr. M. R. Egemen; *Secretary*, Dr. G. Otkun; *Treasurer*, M. Tasman. The objects of the Society are to promote geological research and encourage the study of geology, and to foster contact and collaboration between the various branches of applied geology. Its activities include conferences, lectures and discussions on geological topics; geological excursions both in Turkey and abroad; publication of a bulletin and memoirs of original research; establishment of a library; maintenance of close relations with similar bodies abroad and participation at international geological congresses. Much has already been done since the founding of the Society. Two conferences and an excursion have been held in Ankara, the first of which (February 24–28) comprised papers on local geology, including a comparison of Scotland and Turkey by Prof. W. J. McCallien, of the University of Ankara, and on petrology and geophysics, and a whole-day excursion to the Haymana region south of Ankara. Preparations are now being made for the publication of the first bulletin. The present membership is one hundred, and there are twelve foreign members and correspondents.

South-Eastern Union of Scientific Societies

The fifty-first annual congress of the South-Eastern Union of Scientific Societies will be held at Brighton during July 14–19. The Corporation of Brighton has put the Royal Pavilion at the disposal of the Congress. The president-elect is Prof. W. A. F. Balfour-Browne, who will give an address on "The Possibilities of Natural History". The sectional presidents are E. J. Bedford (botany), A. H. Toms (geology), J. E. Ray (archæology), Prof. G. D. Hale Carpenter (zoology). A morning session will be devoted to a discussion on "The Place of Scientific Societies in the Promotion of Science", based on a circular letter received from the British Association. There will be an evening public lecture and film, "The Beginning of History", dealing with British prehistory, the introductory lecture being given by E. Cecil Curwen, and a film programme for schools designed to promote interest in local natural history and archæology. The honorary general secretary of the Union is H. M. Montford, 23 Mountside, Guildford, Surrey, from whom particulars of the Congress can be obtained.

University of London

The following appointments have been announced: Dr. K. J. Franklin, acting director of the Nuffield Institute for Medical Research, Oxford, to the University chair of physiology tenable at St. Bartholomew's Hospital Medical College, as from October 1; Dr. Margaret M. A. Murray, since 1925 lecturer in physiology at Bedford College, to the University chair of physiology tenable at the College, as from October 1; Dr. Margaret Fishenden, during 1932–45 honorary lecturer in the Mechanical Engineering Department at the Imperial College of Science and Technology and since 1945 senior lecturer in heat transmission, to the University readership in applied heat tenable at the College, as from October 1; Mr. H. E. O. James, since 1926 lecturer in psychology at the University of Manchester, to the University readership in psychology tenable at the Institute of Education, as from October 1.

The title of reader in commerce in the University has been conferred on Mr. Frederick Brown, in respect of the post held by him at the London School of Economics; the title of reader in electrical engineering in the University has been conferred on Mr. C. R. Stoner, in respect of the post held by him at Queen Mary College.

The degree of doctor of science has been conferred on W. J. Martin (Birkbeck College and the London School of Hygiene and Tropical Medicine) and on K. R. S. Morris (external student).

"The Corpus Allatum and the Control of Metamorphosis in Insects"

Dr. V. B. Wigglesworth writes: "In my letter in *Nature* of June 28, p. 872, I omitted, by an oversight, any reference to the important observation by Vogt that the corpus allatum of the first-stage larva of *Drosophila hydei* will induce egg production when implanted into the allatectomized adult female (*Biol. Zbl.*, 63, 467; 1943). This provides further evidence for the identity of the juvenile and yolk-forming hormones."

Announcements

Prof. Linus Pauling, professor of chemistry in the California Institute of Technology, has been appointed George Eastman visiting professor in the University of Oxford for the Hilary and Trinity terms, 1948.

Mr. J. L. Adam, chief surveyor to the British Corporation of Shipping and Aircraft, has been elected president, and Dr. J. H. Paterson vice-president, of the Institute of Welding.

Dr. H. L. Jensen, Macleay bacteriologist of the Linnean Society of New South Wales, Sydney, has been appointed chief of the Division of Bacteriology of the State Laboratory of Plant Culture, Danish Ministry of Agriculture.

At the annual general meeting of the British Standards Institution, held on June 27, Lord McGowan, of Imperial Chemical Industries, Ltd., was elected president in succession to Lord Woolton; and Sir Clifford Paterson, director of the Research Laboratories of the General Electric Co., Ltd., chairman of the General Council in succession to Sir William Larke.

The Society of Dyers and Colourists is organising a symposium on "Recent Advances in the Theory and Practice of Dyeing" to be held at Blackpool during September 25–27. Those likely to attend are asked to communicate with the General Secretary, The Society of Dyers and Colourists, 32–34 Piccadilly, Bradford.

A conference on "Emission Spectra of the Night Sky and Auroras" is to be held in the rooms of the Royal Society during July 7–10. Among the speakers from outside Britain will be G. Dejardin, J. Dufay and R. Bernard (Lyons), D. Barbier, J. Cabannes, A. and E. Vassy, J. Bricard and A. Kastner (Paris), C. T. Elvey (Inyokern, California), J. Kaplan (Los Angeles), M. Nicolet (Brussels), E. O. Hulbert (Washington), R. Grandmontagne (Villeurbanne, Rhone), L. Harang (Tromsö), L. Vegard and C. Størmer (Oslo) and H. Alfvén (Stockholm).

Absorption Spectra with Polarized Infra-Red Radiation

Elliott and Ambrose[1] have described measurements with polarized infra-red radiation. In a previous paper[2], we have explored the use of polarized radiation in studying the absorption spectra of oriented polymers. We have now extended this work by a much-improved technique, using large selenium mirrors to obtain the polarization, and have measured the spectra of many substances between 2 and 15 μ. Particularly interesting results have been found with crystalline solids such as simpler amides, dibenzyl, benzyl and diphenyl acetylene. A small amount of the solid is melted between a pair of rock-salt plates and allowed to crystallize so as to obtain so far as possible a linear orientation of the crystal growth.

When examined in polarized radiation with the direction of crystal growth successively parallel and perpendicular to the plane of polarization, marked spectral changes were found. Bands which are weak in one case are strong in the other; it is probable that the differences would be even more marked and informative if the crystalline orientation could be made more complete. The reality of the effects is proved by replacement of the selenium polarizing mirror by a plane aluminium mirror, when all the bands appearing in either of the other two cases appear together.

A very interesting feature is noticed with some of the amides, where the stretching vibration bands of the $C=O$ and $N-H$ bonds at 1655 cm.$^{-1}$ and 3250 cm.$^{-1}$ appear strong when that of the $N-H$ deformation at 1545 cm.$^{-1}$ is weak, and *vice versa*. This could at once be explained if the amides are associated through hydrogen bridges of the type usually accepted and confirmed spectroscopically[3], namely, involving the link $-C=O\cdots H-N-$. In different amides, which may differ in their internal crystal structure and hence in the arrangement of the bridges, the effect observed varies in degree. The results therefore confirm this type of association, and also provide a new reason for attributing the band at 1545 cm.$^{-1}$ to the deformation of the $N-H$ bond, about which there has recently been some doubt. Moreover, they suggest that it may be possible to use this method in studying the structure of polyamides.

We are extending this work to unstretched and stretched rubbers, derivatives of cellulose, and nylons, with which similar changes have been found, and we are also applying it to peptides and proteins such as myosin. A detailed account will be published later elsewhere.

Polarized Infra-Red Radiation as an Aid to Crystal Analysis

THE optical properties of crystals have been widely used as subsidiary data in X-ray structure analysis. Recent advances in infra-red spectroscopy now make it possible to extend the optical measurements into the region of molecular vibrational frequencies. Since certain infra-red absorption bands of organic molecules can be assigned to vibrations largely localized in certain substituent groups, or to vibrations of the molecule as a whole, a study of infra-red dichroism gives information about the orientation of the groups or molecules in the crystal. For example, if all the molecules in a crystal are equally oriented with respect to the crystal axes, then the minimum absorption of polarized infra-red radiation will be observed when the plane of polarization contains the direction of the change of electric moment produced by the molecular vibration responsible for the absorption. If the crystal contains two sets of mutually inclined molecules, the maximum absorption occurs when the plane of polarization bisects the obtuse angle between the two planes containing the directions of the electric moments and the incident beam. From the ratio of the maximum to minimum optical densities, the angle between the planes can be calculated. Information of this sort can be obtained with the aid of an extremely simple polarizing attachment to a standard infra-red spectrophotometer.

A polarizer was constructed from two surface-aluminized concave mirrors and a plane selenium mirror. The latter was made by melting selenium between a metal plate and a plane glass plate; on cooling, the glass plate was removed, leaving a highly reflecting selenium surface. The first concave mirror was arranged to throw a parallel beam of light from a Nernst filament on to the selenium mirror at the polarizing angle, and the second mirror to condense it on to the crystal sample placed in the usual position relative to the spectrophotometer. The electric vector in the polarized beam was parallel to the length of the slit, and the sample could be rotated about the axis of the beam. The samples were prepared as thin sheets between rock-salt plates by crystallizing from the melt until a parallel growth of crystals was obtained.

The efficiency of the polarizer may be judged from the fact that the transmission of a sample of succinic acid at 2,900 cm.$^{-1}$ decreased from 75 to 1·5 per cent as the plane of polarization was rotated from the [*c*] axis to a perpendicular direction. The [*c*] axes of the acicular crystals in this sample, which was a high-temperature form of unknown crystal structure, were parallel to one another, but the crystals assumed two different orientations about this axis. The great change in absorption of the broad band extending from 3,250 cm.$^{-1}$ to 2,300 cm.$^{-1}$, due to hydrogen-bonded hydroxyl groups, indicates that the $O-H$ bonds must all be nearly parallel to one another and to the [*c*] axis. This is known to be the case in the form stable at room temperature[1].

In the case of a sample of *p*-benzoquinone, tabular on the (100) face, none of the bands showed very intense dichroism. In the crystal structure of benzoquinone determined by X-ray methods[2], the angle between the [*b*] axis and the projection of the $C=O$ bonds on the (100) plane is approximately 33°. Several of the absorption bands, including those associated with the $C=O$ and $C-H$ fundamental frequencies, exhibited dichroism corresponding to angles between 32° and 40°.

As a further test of the method, acetanilide was examined by polarized infra-red radiation, and the conclusions reached were checked by an independent X-ray examination kindly made by Mr. D. E. C. Corbridge, of these Laboratories.

In the sample examined, the crystals (space group P_{bca}) formed as needles elongated along the [*b*] axis and tabular on (100). Most of the bands exhibited a maximum absorption parallel to the [*b*] axis, but a few, including that at 759 cm.$^{-1}$ attributed to the flapping motion of the benzene ring, exhibited a maximum absorption parallel to the [*c*] axis. From the ratio of maximum to minimum optical densities of the various bands, it was calculated that the benzene rings were inclined at about 20° to the (001) plane, and the projections on (100) of the hydrogen-bonded N—H and C=O bonds were each inclined at about 30° to the [*b*] axis. From the observed optical densities, it was estimated that the C_6H_5—N bonds must lie at a fairly small angle to the [*a*] axis. These conclusions are in agreement with the general arrangement of the molecules as deduced from the preliminary X-ray study.

A further possibility, which has not yet been examined, is to reverse the process and use the infra-red dichroism of crystals of known structure to analyse the infra-red spectra or to check proposed assignments of fundamental frequencies.

Oxidation of Neostrychnine

The action of bromine on neostrychnine, $C_{21}H_{22}O_2N_2$, in cold acid solution affords a bromohydrobromide transformed by hot water into the hydrobromide of oxodihydroallostrychnine (formerly called oxodihydroneostrychnine), $C_{21}H_{22}O_3N_2$, in nearly theoretical yield. This substance has now been recognized as an aldehyde, and its formation involves a molecular rearrangement, :N.CH = C: → :N—C(CHO):. It is noteworthy that the reverse transformation can be realized. Catalytic reduction of the aldehyde in alcoholic solution gives a dihydro-derivative, probably the related primary alcohol; in acetic acid solution an isomeride is produced in addition, and this is converted with great ease by dilute mineral acids into neostrychnine. Nitrous acid transforms neostrychnine into a ketoxime-formamide, : N.CH : C : → : N.CHO HON : C:, which is hydrolysed by dilute hydrochloric acid to hydroxylamine, formic acid and a hydrochloride, $C_{20}H_{23}O_3N_2Cl$. This is a salt of a *sec*-basic ketone.

Taking into consideration what is already known in regard to the environment of the basic nitrogen of strychnine, these observations establish the relation of neostrychnine to strychnine. Under the influence of Raney nickel (and in other ways in certain derivatives), the double bond moves just one step in the direction of the basic nitrogen atom. This implies a new view of the methoxylating fission of the metho-salts of the alkaloids.

The direct explanation of the formation of oxodihydroneostrychnine (now termed oxodihydroallostrychnine) and its reconversion to neostrychnine was

$$\text{—CH:C(N:).} \rightarrow \text{—CO.CH(N:).} \rightarrow \text{—CH(OH).CH(N:).} \rightarrow \text{—CH:C(N:),}$$

and on this basis the older type of formula for strychnine was untenable. The discovery of unexpected and somewhat remarkable molecular rearrangements disposes of this natural explanation. It does not disprove the quinuclidine formula recently proposed[1]; but it removes the necessity for its postulation and, in these circumstances, we revert, as the best hypothesis to guide future work, to an earlier suggestion[2]. The relation of this structure to that of cinchonine has already been indicated[3]. Several slight modifications of this expression are feasible, and these have special advantages and disadvantages which must be discussed at a later date, especially since it is probable that crucial experimental tests can be devised.

Fluorescence of Cancerous and Non-Cancerous Lipoids

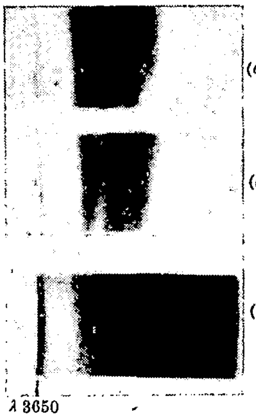
In a previous communication, evidence was given[1] indicating the presence in human cancer tissue of a fraction, or fractions, the fluorescent spectra of which were similar to, if not identical with, those produced by methylcholanthrene. The fluorescence produced in a similarly treated lipoid fraction obtained from non-cancerous livers was considerably weaker, and appeared in a different region of the spectrum.

These findings were disputed by Hieger[2], and, in an exhaustive study of lipoids obtained from human cancerous and non-cancerous livers, Jones and May[3] failed to identify any methylcholanthrene-like compounds in human cancer tissue.

It should be emphasized at the outset that the expression 'methylcholanthrene-like' referred specifically to the similarity of the bands produced by the two substances. However, since even the existence of such bands in cancerous liver lipoids was questioned, the present work was undertaken to check the original contention, and to secure a more satisfactory procedure for the isolation and concentration of the material giving the banded fluorescent spectrum. A method was finally developed which has given fairly consistent results. Briefly stated, the procedure is as follows.

The acetone-soluble fraction is obtained as already described[4]. This lipoid is then saponified with 10 per cent potassium hydroxide in 70 per cent ethanol in a ratio of 1 : 10 for 24 hours. The ethanol is removed, the residue taken up in ethyl ether, and washed with distilled water until neutral to litmus. The solvent is then removed and the residue resaponified for four hours. The final residue is taken up in acetone and a part of the free cholesterol removed by refrigeration and filtration. After the removal of the acetone, the residue is taken up in hexane, passed through a column of activated alumina, and developed with hexane. This resolves the lipoid into three main fractions: (1) the upper third of the column is occupied by a light brown to yellow zone; (2) a light-bluish fluorescent zone comprising the rest of the column; (3) a filtrate. The column is then partly dried by air, the two fractions separated, extracted repeatedly with methanol, and filtered. The methanol is removed under reduced pressure and the residue taken up in hexane. The yellow material (top zone) is then passed through a column of silicic acid. This resolves the lipoid into four to six bands of various gradation of brown (from dark to light), a pink and red band, and on repeated washing, a zone of blue fluorescence at the bottom of the column. The lower fraction is separated, extracted with methanol, which is later removed at reduced pressure, the residue is taken up in hexane, and photographed as previously described[1]. An alternate procedure is to treat this fraction by repeated washings with hexane, and recover it from the filtrate.

As to the other fractions appearing in the column, they give either a continuous spectrum or are non-fluorescent. Quantitatively, the recovery of this material varies. In a typical instance, about 2,400 gm. of tissue will yield 56 gm. of total lipoid. Upon saponification the latter will give 1·5 gm. of unsaponifiable material. After passing it through a column of activated alumina, and then through a column of silicic acid, the material will give 15 mgm. of bluish fluorescent material, producing the characteristic spectroscopic banded structure.



(a) FLUORESCENCE OF FRACTION FROM CANCEROUS TISSUE; (b) FLUORESCENCE OF METHYLCHOLANTHRENE; (c) FLUORESCENCE OF FRACTION FROM NORMAL TISSUE

The results illustrated by the figures are self-explanatory. The bands obtained from the cancerous unsaponifiable fraction show a slight shift toward the 3650 mercury line, and do not agree exactly with the bands produced by methylcholanthrene. On all three spectrograms the long wave-length is to the right of the 3650 line of mercury. The 'bands' in (a) are shifted slightly to the violet relative to those in (b). When the originals of (a) and (c) are compared it looks as if the same bands occur on the two plates. The intensity of the fluorescence in the normal is too low to prevent the mercury lines 4047, 4074 and 4358 from coming through. That, and a shift of intensity toward the red, gives us the difference in the two plates. It seems reasonable to conclude that the fluorescences in (a) and in (c) arise from the same substance. The substance is present in greater amounts in cancerous than in non-cancerous material.

The comparison with methylcholanthrene does not imply the presence in the cancerous lipoid of a fraction identical with the known carcinogens. It indicates: (1) the presence of substances giving banded structures in the unsaponifiable fraction obtained from cancerous livers, and, to a certain extent, in non-cancerous livers; and (2) the close similarity between the bands obtained from a fraction endogenous in character, and a synthetically prepared exogenous compound.

This material was found on analysis to consist largely of a saturated hydrocarbon which on catalytic micro-hydrogenation failed to take up hydrogen. Since the saturated hydrocarbon could not be responsible for the fluorescence, it is evident that the latter is due to a component or 'admixture', and present in a relatively very small amount. Investigation of this fraction is now in progress.

This work was repeated and confirmed by Dr. B. Krichesky, associate professor of zoology, at the University of California, at Los Angeles. A detailed report of the method employed will be published elsewhere.

These investigations were supported by a grant from the Jewish Fund for Medical Research to the University of California and carried out under the supervision of the Committee on Cancer Research.

Molecular Compounds Involving Copper Diphenylacetate

The copper salts of many organic carboxylic acids are soluble in alcohol (see Beilstein). It has now been found that although a few are soluble in benzene, for example, copper hydrocinnamate, many which are insoluble in benzene will dissolve readily on addition of a few drops of alcohol; for example, copper phenylacetate, diphenylacetate, *o*-toluate.

Copper diphenylacetate has been studied in more detail. This compound crystallizes from hot absolute alcohol in large light-green octahedral crystals containing two molecules of alcohol. The combined alcohol is lost on standing in the open, and the crystals become darker in colour without apparent change in form. The light-green material containing alcohol is readily soluble in benzene, whereas the darker green compound is not. If copper diphenylacetate is crystallized from aqueous alcohol, needle crystals are obtained without alcohol, and these are insoluble in benzene.

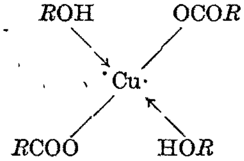
It would seem from this that the substance possessing benzene solubility is $CuA_2.2EtOH$ (where A is the diphenylacetate radical). The molecular weight of this compound determined cryoscopically in benzene varied from 350 to 430 with the concentration. This is lower than the calculated value of 578, but shows that there is only one atom of copper in the molecule.

Copper diphenylacetate combines with many other alcohols. The following have been investigated :

Alcohol	Crystalline form	Mols. alcohol : mols. CuA_2
PRIMARY		
Methyl	—	no compound isolated
Ethyl	octahedra	2 : 1
n-Propyl	octahedra	2 : 1
n-Butyl	octahedra	2 : 1
n-Amyl	octahedra	2 : 1
n-Octadecyl	—	no compound isolated
iso-Butyl	octahedra	2 : 1
Allyl	octahedra	2 : 1
Benzyl	needles	2 : 1
SECONDARY		
iso-Propyl	—	no compound isolated
sec-Butyl	prisms	indefinite
cyclo-Hexanol	needles	1 : 1
TERTIARY		
tert-Butyl	plates	2 : 1
Amylene hydrate	needles	1 : 1
Triphenylcarbinol	—	no compound isolated

The last two compounds with tertiary alcohols are remarkable in being quite stable in contact with the atmosphere.

In the 2 : 1 compounds, it is probable that the alcohol molecules are linked to the copper atom by donation of electrons from their oxygen atoms :



Cis and *trans* arrangements would be possible if the copper atom had the usual planar valency distribution. These have not so far been observed.

The combining powers of copper diphenylacetate are not restricted to alcohols. Acetone gives a 1 : 1 compound (plates), ethyl acetate a compound of indefinite composition (plates), aldehydes dissolve copper diphenylacetate very readily, and pyridine gives a 1 : 4 compound (azure hexagonal plates).

Publication in full will be made elsewhere. The comparative solubility of copper salts of organic acids is being investigated.

Highly Active Triphenylethylene Derivatives

TRIPHENYLETHYLENE[1] and several active derivatives[2-4] have been shown to possess a prolonged œstrogenic activity provided that a dose well above the threshold is administered. Among these, αα-di-(*p*-ethoxyphenyl)-β-phenylbromoethylene[4] has been especially noted for its considerable prolonged œstrogenic activity when administered orally. A considerable prolonged action has also been noted[5] when a dose well above the threshold of diethylstilbœstrol dimethyl ether is administered subcutaneously. Emmens[6] has attributed the prolonged action shown on injection of the higher doses of methyl ethers of diethylstilbœstrol and of œstrone to "the slowness with which the body effects hydrolysis of such ethers, without which they cannot be esterified and excreted".

αα-Di-(*p*-hydroxyphenyl)-β-phenylbromoethylene (m.p. 205–7°) has been found to possess, when administered by subcutaneous injection, a relatively high potency; but the duration time, like that of diethylstilbœstrol[5], is not appreciably increased with increased dosage. When administered by subcutaneous injection, its diacetate ester (m.p. 157–159°) has a more prolonged action, and its minimal effective dose is lower. In contrast to αα-di-(*p*-ethoxyphenyl)-β-phenylbromoethylene, which is a pro-œstrogen[7], both αα-di-(*p*-hydroxyphenyl)-β-phenylbromoethylene and its diacetate ester have been found to be true œstrogens.

αα-Di-(*p*-hydroxyphenyl)-β-phenylbromoethylene is readily obtained from αα-di-(*p*-isopropoxyphenyl)-β-phenylbromoethylene (m.p. 116–118°). The latter is prepared by brominating αα-di-(*p*-isopropoxyphenyl)-β-phenylethylene (m.p. 83–84°). On heating αα-di-(*p*-isopropoxyphenyl)-β-phenylethylene in vacuum at 220–230° with a drop of 20 per cent sulphuric acid, αα-di-(*p*-hydroxyphenyl)-β-phenylethylene (m.p. 178°) is obtained in quantitative yield. αα-Di-(*p*-acetoxyphenyl)-β-phenylethylene (m.p. 84°) and αα-di-(*p*-propionoxyphenyl)-β-phenylethylene (sinters at 62° and melts at 65–66°) are obtained by heating αα-di-(*p*-hydroxyphenyl)-β-phenylethylene with acetic anhydride and propionic anhydride respectively. αα-Di-(*p*-acetoxyphenyl)-β-phenylbromoethylene has been prepared by brominating αα-di-(*p*-acetoxyphenyl)-β-phenylethylene.

The œstrogenic activity of some triphenylethylene derivatives is shown in the accompanying table. The substances were dissolved in oily solution.

Substance	Subcutaneous injection		Oral administration (stomach tube)	
	Dose (μgm.)	Duration until action halved (days)	Dose (μgm.)	Duration until action halved (days)
αα-Di-(*p*-hydroxyphenyl)-β-phenylethylene	50 75 100 200 375 750	Slight effect 2 2 3 3 4	1000	Nil

A Volatile Compound of Copper

IN search of the cause of a copper deposit formed in some incandescent lamps with copper electrodes, we examined the thermal decomposition of some organic copper salts. Cuprioxalate yields copper oxides, and cuprimesoxalate a mixture of copper oxides with elementary carbon. Cupriformate, however, decomposes at about 200° C., evolving partially a volatile compound of copper which immediately decomposes, forming a red smoke of elementary copper, and coating the near hot glass surface with a brilliant mirror of metallic copper. Where this mirror was thin, it resembled in every way the red deposit found in incandescent lamps.

Cupriformate may be decomposed in a horizontal glass tube in a stream of non-oxidizing gas, and its volatile product of decomposition is thus carried quickly out of the hot zone and saved from decomposition. It may be transported by the gas through a dense filter of cotton wool several centimetres long in a glass tube over a distance of more than 40 cm., and if the gas is ignited there, the new compound makes the flame an intense green. If, however, a remote part of the tube through which the compound is swept by the gas is heated externally, a beautiful copper mirror is formed. The unheated part of the tube between the cupriformate and the heated section remains absolutely clear. In a preliminary experiment, more than 1 per cent of the copper present in the decomposed cupriformate was recovered in the remote mirror. This reaction is useful in the quantitative study of the behaviour of the new compound, the isolation of which has not yet been accomplished. It is readily adsorbed on glass wool and to some extent on cotton. It condenses together with droplets of water—resulting from the formate—on the glass tube, and may be driven thence by gentle heating. The diluted gas stream is uncoloured; but around the decomposing cupriformate the gas phase is sometimes olive-green.

Formates of nickel, iron, cobalt, zinc and cadmium decompose without mirror formation. The extremely labile silver formate, however, yields a mirror on thermal decomposition, and silver oxide does the same when heated in a stream of reducing gas containing formic acid vapour. It is interesting that this reaction of the formates is not observed with the carbonyl-forming metals but occurs with two metals of the first sub-group of the periodic system. Experiments with gold are in progress. *Feb.* 21.

The existence of a copper carbonyl has been already postulated[1-4] but was seemingly disproved by Mond and Heberlein[5], who found no copper mirror in a glass tube after passing a mixture of carbon dioxide and monoxide over cupric oxide. In a recent communication in *Nature*, H. Bloom[6] reports having confirmed Bertrand's[2] original claim. His experiments are convincing in respect to the formation of a volatile copper compound, which is probably identical with the one formed from cupriformate. The term 'copper carbonyl', however, needs further examination. At the beginning we also thought that we were dealing with a carbonyl, but the facts that (1) the formates of the carbonyl-forming metals are inactive and (2) that of the three copper salts examined the two yielding carbon monoxide and dioxide were inactive, and only the formate, which contains hydrogen, was found active, made us hesitate. Experiments quite similar to those of Bloom showed mirror formation only if at least traces of organic compounds containing hydrogen were present in the gas. Metallic copper never reacted, only the oxide, and that only if a reducing gas was used. It would be very interesting to repeat Bloom's experiment with carbon monoxide carefully purified from all traces of hydrogen compounds. Convincing evidence will be available only after isolation and analysis of the new compound. Experiments to this end are in progress.

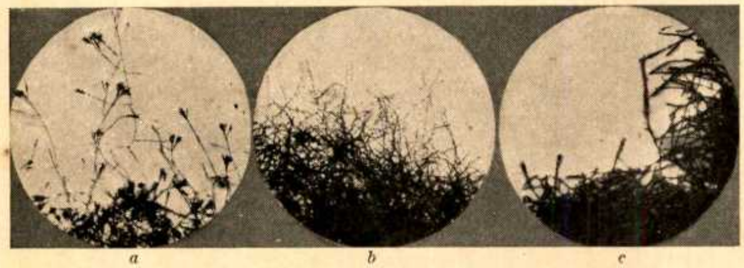
Action of 2-Aminofluorene on Moulds

Bielschowsky and Green[1] have noticed that 2-aminofluorene at a concentration of 1 : 10,000 is a growth inhibitor for *Staphylococcus aureus*. Such observations have been confirmed[2] and amplified by us. The influence exercised by this compound on two strains of *Penicillium* studied by us seems to us to be of particular interest.

Penicillium notatum Westling, strain 1219, is considerably hindered in its growth by saturating with 2-aminofluorene the Czapek–Turley medium, in which this substance dissolves only in traces. It is necessary first to sterilize the aminofluorene and then add it to the medium, otherwise the composition would be changed by heating. It seems that only sterile hyphæ are formed; there is no formation of characteristic conidiophore filaments. The hyphæ in coloured preparations appear to end with simple club-shaped swellings, or are reduced to fragments without causing the formation of conidia (see photographs); only very slowly does a sign appear of the formation of exospores.

At the second subculture, the growth on the surface is very seriously hindered, the mould developing mainly in the shape of isolated colonies at the bottom of the culture medium. At the same time, there are some modifications in the aspect of the culture, which shows a white colouring on the surface, without any sign of the characteristic blue-green colour on the surface of the crests of the folds as in the parent strain, while the mycelium on the reverse side takes a pink colour instead of golden yellow as in the original culture. The solution is much less intensely and much more slowly coloured, the production of penicillin being strongly hindered.

A somewhat different behaviour was shown by another variety of *Penicillium* isolated in this laboratory which secretes a bacteriostatic substance, active not only on Gram-positive organisms (staphylococci) but also on Gram-negative ones (typhus, cholera, etc.), that is, on micro-organisms against which the 2-aminofluorene has no bacteriostatic action. This mould, cultivated on mediums with 2-aminofluorene, also grows first without formation of conidia and looks like a white felt made of intertwined sterile hyphæ; but it accommodates itself more rapidly, and the conidiophore filaments with globular conidia of a characteristic dark green colour soon appear in isolated, later on confluent, zones. At the same time, and suddenly, the metabolism solution becomes a reddish-brown colour of a more intense hue, as compared with the control cultures cultivated on Turley medium of the same age. In successive transplantations the pigment appears more rapidly and is more intense, and the formation of the conidia seems to be less hindered, though the whole culture shows signs of suffering. A characteristic is the behaviour of the bacteriostatic action, which in the metabolic solutions of the moulds, cultivated on medium to which 2-aminofluorene has been added, appears after some delay, but reaches higher values and persists much longer, at least in the first transfers, both with Gram-positive and Gram-negative micro-organisms.



Pen. notatum WESTLING. CULTURE 4 DAYS OLD. × 25. *a*, PARENT STRAIN ON TURLEY'S MEDIUM; *b* and *c*, GROWTH ON TURLEY'S MEDIUM WITH 2-AMINOFLUORENE

Besides the bacteriostatic action on the pyogenic staphylococcus observed by Bielschowsky, the 2-aminofluorene, therefore, interferes also with the metabolism of the moulds by hindering the formation of the exospores, modifying their mode of living, in some cases exciting and in others inhibiting the production of bacteriostatic substances.

Pteroylglutamic Acid in Liver Extracts and Urine

IN order to undergo pupation and emergence, the larva of *Aedes ægypti* L. is dependent on the presence of 'folic acid' in the medium[1]. The use of water-extracted yeast residue makes it possible to replace the 'folic acid' of Williams by synthetic pteroylglutamic acid (*L. casei* liver factor) but not by thymine (in quantities up to 1 gm. per l. of medium) or by xanthopterin[1,2]. On the basis of these findings, we have used the metamorphosis of mosquito larvæ as a test for pteroylglutamic acid in liver extracts and urine.

Commercial liver extracts were tested at levels of 20 ml. ('crude' extracts) and 8 ml. ('refined' extracts) per l. of medium. Six liver preparations of established clinical potency were used, but only four were found capable of inducing pupation and emergence of the larvæ. The results for the three best 'refined' extracts were as follows:

Extract	Dry matter content	Larval response
A	170 mgm. per 1 ml.*	Strongly positive
B	140 mgm. per 2 ml.	Weakly positive
C	30–40 mgm. per 1 ml.	Negative

* The volumes quoted in each case represent 100 gm. fresh liver.

These observations may be accounted for on the basis of the different contents of pteroylglutamic acid, which do not appear to be related to the level of anti-pernicious anæmia factor present. Furthermore, the fact that a potent preparation such as *C* gives no larval response indicates that the anti-pernicious anæmia factor is incapable of bringing about pupation and emergence of mosquito larvæ.

Concentrates from 24-hour specimens of urine were prepared by a modification of the method of Wilkinson, Klein, Ashford, Jones, Mainwaring and Aylward[3]. In the urines of seven normal subjects, two of whom were tested twice, no pteroylglutamic acid could be detected. This result is in keeping with the observations of other workers[4-6], who found by microbiological assay that only a trace of 'folic acid' is excreted in human urine. In three of our normal subjects, assay by means of *S. lactis R*[7] showed the 24-hour urinary excretion of stimulating factor to be less than 0·6 μgm.

Four normal subjects were each given a course of liver injections intramuscularly, two receiving extract *A* and the others extract *C*. The total volumes administered in this way were 6 ml. and 8 ml. respectively. Twenty-four hour urine specimens were collected immediately following the termination of the liver treatment and again two weeks later. In all cases the larval response was negative, indicating that the excretion of pteroylglutamic acid had remained low. Over a long period it was found possible to carry out tests on similar lines on nine untreated patients with pernicious anæmia, each case being carefully investigated to establish the correctness of the diagnosis. The mosquito larva test was applied to the urine of these patients before and after liver therapy. The results are summarized below. As a negative control may be cited a case of myxœdema associated with macrocytic normochromic anæmia, which before and after thyroid and liver treatment showed little or no excretion of pteroylglutamic acid.

Although the number of cases investigated falls far short of what is desirable, there is a strong indication that clinical response to liver therapy is followed by greatly increased excretion of pteroylglutamic acid; that this increase bears no relation to any pteroylglutamic acid which may be present in the liver extract used; and that when liver is administered to normal or non-responsive subjects, pteroylglutamic acid excretion remains at a low level. The possibility of a dynamic relationship between pteroylglutamic acid and the anti-pernicious anæmia factor suggests itself.

Patient	M. larva test before treatment	Liver extract used*	Clinical response	M. larva test following treatment
1	–	*A*	+	+
2	–	*C*	+	+
3	±	*C*	+	+
4	–	*C*	+	+
5	±	*C*	+	+
6	–	*B*	+	–
7	–	*B*	–	–
		A	–	–
8 and 9	–	No further urine specimens secured.		

* The volumes of extract given were: *A* 3 ml., *B* and *C* 6–8 ml.

We should like to express our indebtedness to Prof. R. J. Williams for a specimen of 'folic acid' and to Dr. E. L. R. Stokstad for a supply of pteroylglutamic acid. Our thanks are also due to all those who co-operated in the collection of urine specimens, and to Miss M. Currie, Miss S. Sussman and Mr. J. M. Thorp for technical assistance.

Dependence of Anomaloscope Matching on Viewing Distance or Field Size

FOR the rapid detection of defective colour vision in personnel untrained in the use of optical instruments, an anomaloscope has been constructed in which a bipartite test field of 18 mm. diameter is viewed direct with both eyes. One half of the field is illuminated by light passing through a narrow-cut yellow filter (Ilford No. 812, maximum transmission at 580 mμ), and the other half by a variable mixture of the lights from a narrow-cut red filter (Ilford No. 608, transmitting above 640 mμ) and a narrow-cut green filter (Ilford No. 807, maximum transmission at 530 mμ). The instrument was designed so that the proportions of red and green light in the mixed half of the field could be obtained with fair accuracy from the reading of a single scale, and a control was provided for adjusting the brightness of the other half of the field. The brightness of the field was about 10 candles per sq. metre, permitting observations to be made in artificial light or dim daylight.

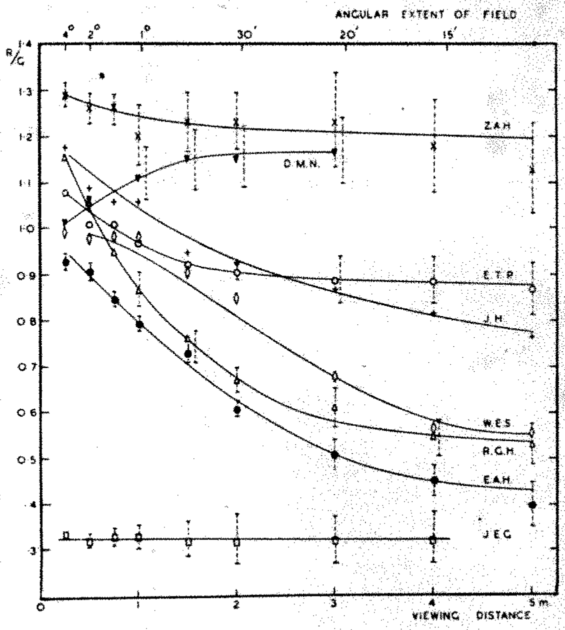

Fig. 1

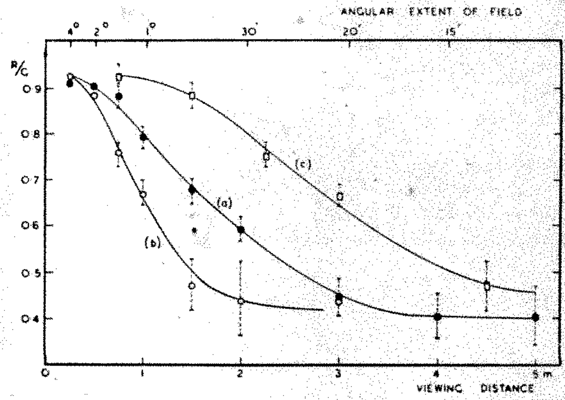

Fig. 2

It was found that the relative amount of red and green light (R/G) required to match the yellow was dependent on the viewing distance. The effect was so striking that most people, when shown their own 50-cm. match at a distance of 2 or 3 metres, at first believed the controls to have been altered.

Variation of the R/G ratio with viewing distance for a number of observers is shown in Fig. 1. In plotting these results, the average value of the ratio obtained by normal observers for a 2° field (that is, at 50 cm.) has been adjusted to equal unity. Where confusion would not thereby be introduced, dotted lines have been added to indicate the range outside which the observer definitely refused to accept any ratio as a match. It seems that individual observers show considerable differences in their types of behaviour, and that a group of observers who would be judged as normal at a short distance give widely different values of R/G at the longer distances even when allowance is made for the reduced precision. For most observers the amount of green required in the mixed field increases with the distance, and it will be noticed that the normal observer, E. A. H., requires almost as much green as the deuteranomalous observer, J. E. G., when the distance is increased beyond 3 metres.

Fig. 2 shows the results obtained by a reliable observer with a normal 18-mm. field, curve (*a*), and with a 6-mm. field, curve (*b*), plotted on the same distance scale. Curve (*c*) also applies to the 6-mm. field, but is plotted on the same angular scale as (*a*). It appears that the R/G ratio is not determined solely either by the viewing distance or by the angular extent of the field. Difficulties of accommodation and fixation, and visual aberrations, may be responsible for divergencies which, if absent, would allow the ratio to show a simple dependence on the angular extent of the field.

Whether this is true or not, it would seem desirable that investigators carrying out field inquiries with anomaloscopes of this class should pay some attention to the field-size and the viewing distance of the instruments they employ.

In view of the known peculiarities of colour vision within the central fovea, it is not surprising that effects of the type described should be found with angular fields of, say, less than 30′. It is more surprising that such effects should extend to angular fields between 1° and 3°, within which the colour-matching properties of the fovea are usually assumed to be independent of the field size.

We have asked many people if they have observed this effect before, but only Dr. J. H. Shaxby appears to have noticed it. He observed the effect when constructing his anomaloscopes, and agrees with us that it can only be because such instruments are generally fitted with eyepieces, and therefore have a fixed angle of view, that the effect is not more widely known.

R. G. Horner
E. T. Purslow

Physics Research Laboratory,
Ilford Ltd.,
Brentwood,
Essex.
April 3.

Mr. R. G. Horner and Mr. E. T. Purslow have made a detailed study of the fact that the red-green ratio required to match a given yellow in the anomaloscope is dependent to a marked extent upon the distance of viewing (or the angular field). I observed this effect in my anomaloscope[1], and one of my students made a study of it. He is now unfortunately inaccessible, being in the Navy, and I am unable to quote his measurements; but his findings were approximately those given by Horner and Purslow, namely, a rapid change in the ratio at small distances, settling down to a constant value where the distance is large, that is, the angular field sufficiently small.

The peculiarities of central foveal vision alluded to by Horner and Purslow are presumably largely responsible for the change; though it must be noted that in my instrument the actual ratio of red to green light in the observed field must tend to vary with distance owing to the unequal scattering of green and red by the 'Diffusalyte' glass and the restriction of the light viewed to a smaller and more definite angle at greater distances.

Shock Wave in Glass

During tests with an experimental high-speed camera developed at the National Research Laboratories[1], the photographs reproduced herewith (Fig. 1) were taken of a shock wave travelling through glass. The pictures indicate that the wave must travel through the glass at a speed of more than 18,500 ft. per sec.

The method of generating the shock wave is shown in Fig. 2. A 0·010-in. diameter copper wire was sealed through a 3/8-in. diameter × 10 in. long 'Pyrex' glass rod as shown. The copper wire was exploded electrically by discharging through it a 4 Mfd. condenser charged to 10,000 volts. An inch scale was marked on the illuminated background to facilitate measurement of velocity.

The high-speed photographs were taken in the order *A*-9, *A*-10, *B*-1, *B*-2, etc., with a time-interval between successive pictures of 15 micro-sec. A piece of black paper was placed in the lower right corner of the field to mask the flare from the exploding wire. This mask is seen in the photographs, obscuring the glass rod up to one inch above the wire.

The copper wire is seen to explode in picture *B*-3. In *B*-6, that is, 45 micro-sec. later, the upper end of the rod 10 in. away has been shattered. This implies that a shock wave travels along the glass with a speed of at least 18,500 ft. per sec. It is also apparent from the photographs that the glass does not shatter until some time after the shock wave

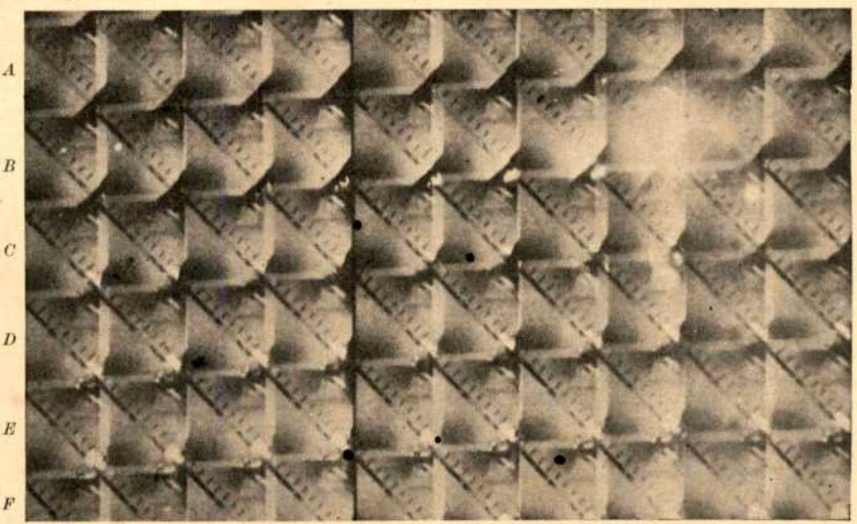

Fig. 1

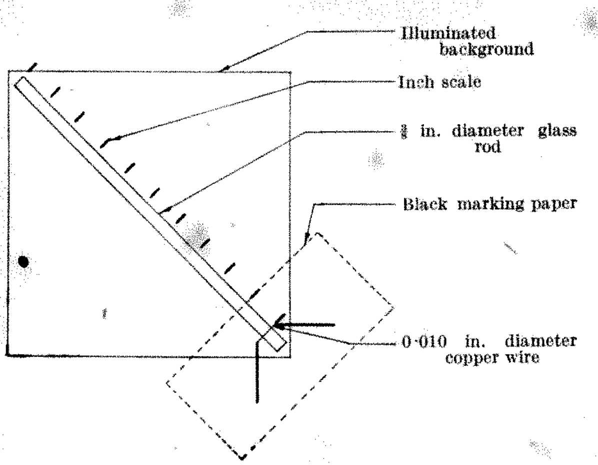

Fig. 2

has passed. It will be noted, for example, that the part of the rod three to four inches from the upper end has not broken until some time after the portions on either side of that region. Further, the time between the explosion and the shattering of the glass 3 in. from the lower end is considerably greater than the time between the shattering at the latter place and that at the upper end 7 in. farther along, that is, the shattering does not proceed along the rod with a definite velocity. It is inferred from this that after the shock wave has passed, the glass proceeds to shatter in the places where stresses are already concentrated, for example, at the end of the rod, or where annealing was poor. Thus the speed of the shock wave itself may be considerably greater than 18,500 ft. per sec. Indeed, the time between shattering at the 3-in. mark and the 10-in. mark is only 15 micro-sec., corresponding to a velocity of almost 39,000 ft. per sec.

Some portions of the rod as long as an inch were intact after the experiment, having apparently transmitted the very violent shock without fracturing. The portions that show opaque in the photographs were reduced to pieces the size of particles of sand.

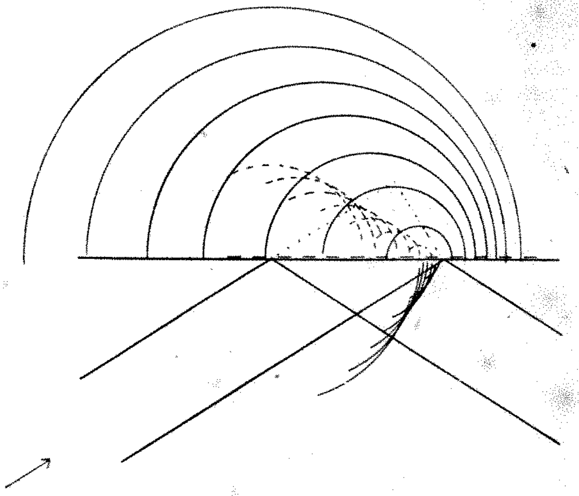
Total Internal Reflexion and Huyghens' Construction: the Immersion Grating

It is not uncommonly supposed that if light falls on a dense-rare interface at more than the critical angle, no energy can penetrate into the rarer medium. Several workers[1] have shown that a certain amount of energy can penetrate a short distance, but that the disturbance is much attenuated and becomes negligible at a few wave-lengths distance from the interface. This is in accordance with Huyghens' construction[2] (see diagram, full circles), which gives in this case a series of secondary wavelets lying wholly within their neighbours, and hence not cutting and reinforcing at any considerable distance.

These secondary wavelets in the rarer medium can be made sensible and clearly visible by the use of a 90°, 45°, 45° prism (kindly prepared by the British Scientific Instrument Research Association), which has an array of opaque silver squares on its hypotenuse face, the intervening spaces being strips of clear glass-air interface. The silver suppresses some of the secondary wavelets, allowing the others to reinforce each other, in a number of directions, given by the generalized equation for an interfacial grating:



HUYGHENS' CONSTRUCTION FOR TOTAL INTERNAL REFLEXION
Full circles, conventional construction. Broken circles, showing wavelets emerging from a grating and reinforcing each other in the rarer medium

$$\frac{n\lambda}{d} = \mu_1 \sin\theta_1 + \mu_2 \sin\theta_2, \qquad (1)$$

where d is the grating space, λ the wave-length, n an integer, θ_1 and θ_2 the angles between the incident and emergent light and the normal in media of refractive index μ_1 and μ_2. θ_1 and θ_2 have the same sign if they are on the same side of the normal. The process is shown by the dotted circles in the diagram, which have been drawn an integral number of wave-lengths inside the corresponding and concentric full circles, with centres at the clear points of the interfacial grating.

If the treated prism is placed on the table of the spectrometer with the light incident at slightly less than the critical angle, the ordinary refracted beam (= zero order spectrum) emerges in the usual way and is clearly recognized by its intensity. If the prism be now turned slowly on the table to increase the angle of incidence, the refracted beam being followed in the telescope, the refracted beam disappears as expected when the angle of incidence becomes critical, but the higher order of spectra remain. In this way spectra have been observed emerging when the angle of incidence exceeds the critical by 25′ of arc.

A study of equation (1) suggests several possibilities. First, the device can be used for suppressing the zero order of a set of spectra or any other Fraunhofer diffraction pattern. Secondly, by putting μ_1 and $\mu_2 \sim 1{\cdot}7$, and θ_1 and θ_2 both positive and 65–70°, we can push up the value of the right-hand side to ~ 3. Thus if a very fine grating ($d \sim \lambda/3$) could be ruled on a transparent base of high refractive index, and a sandwich made of it with two prisms and liquid films of suitable refractive index, one could calibrate it using an optical spectrum in the first order. For contrast, μ_1 and μ_2 should both be high but different. Such a grating could then be used in the ultra-violet and soft X-ray region with added confidence. It could be called an 'immersion grating'.

Since a dense-rare interface becomes permeable to undulatory energy if ruled with a grating, it is clear that the classical explanation[3] of the production of X-ray spectra by glancing 'total internal' reflexion from a ruled glass or metal surface requires reconsideration.

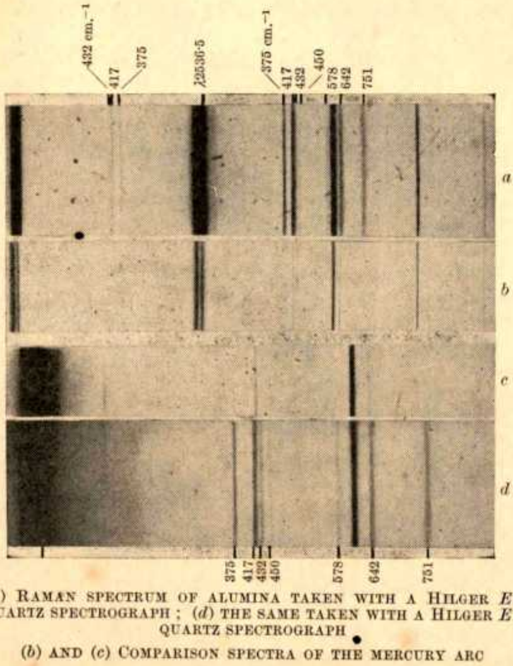
Raman Spectrum of Alumina and the Luminescence and Absorption Spectra of Ruby

STUDIES of the Raman spectrum of crystalline alumina are rather scanty and incomplete, evidently because of its comparative feebleness and a continuous fluorescence accompanying it. Deutschbein[1], who was the first to investigate the case, recorded only a single frequency shift of 415 cm.$^{-1}$. Later, a second Raman line with a frequency shift of 376 cm.$^{-1}$ was noticed by Miss A. Mani[2]. A subsequent unpublished investigation by the latter[3] gave a hint of the existence of other faint lines besides the two already reported, among which two with frequency shifts 752 cm.$^{-1}$ and 633 cm.$^{-1}$ appeared most definite. It seemed likely that the use of the intense λ 2536·5 mercury resonance radiation as exciter would yield a much more satisfactory Raman spectrum for the substance. This hope has been realized in the present investigation. A large boule of synthetic alumina presented to Sir C. V. Raman by the Linde Air Products Co. of New York gave satisfactory results: unlike the majority of samples of synthetic alumina, this particular one did not become coloured under ultraviolet irradiation.



(*a*) RAMAN SPECTRUM OF ALUMINA TAKEN WITH A HILGER *E*3 QUARTZ SPECTROGRAPH; (*d*) THE SAME TAKEN WITH A HILGER *E*1 QUARTZ SPECTROGRAPH

(*b*) AND (*c*) COMPARISON SPECTRA OF THE MERCURY ARC

Seven Raman lines with frequency shifts 375 (8), 417 (10), 432 (4), 450 (2), 578 (3), 642 (6) and 751 (7) cm.$^{-1}$ have been recorded in the alumina spectrum. The figures in brackets represent rough estimates of the relative intensities of the lines. Their positions as well as frequency shifts are marked in the accompanying spectrograms. A preliminary examination of the polarization characters indicated that the lines with frequency shifts 751 and 578 cm.$^{-1}$ should be assigned to the symmetric class and the rest to the degenerate class of vibrations. It is satisfactory to note that these results are in accord with the theoretical work of Bhagavantam and Venkatrayudu[4], who showed that the unit cell containing two Al_2O_3 groups has eighteen distinct frequencies of atomic vibration, of which two of the totally symmetric class and five of the doubly degenerate class should be active in the Raman effect.

The foregoing results are of interest in relation to the luminescence and absorption spectra of ruby which, as is well known, is crystalline alumina with chromic oxide impurity present as a colouring agent. The electronic transitions of the Cr^{+++} ion are responsible for the two intense lines at 6927 and 6942 A., as well as a few other fainter lines in the neighbourhood appearing at the same position in luminescence and absorption. Besides these, there is a host of bands appearing on both sides of the principal doublet which become sharper at low temperatures: they are then more intense on the longer wave-length side in luminescence and on the shorter wave-length side in absorption. The suggestion[1,2] that these may arise from the combination of the vibration frequencies of the alumina lattice with the electronic transitions of Cr^{+++} ions has been fully confirmed by the present investigation. In fact, nearly all the bands have been satisfactorily explained by taking account of the seven Raman frequencies as well as the lattice frequencies which are active in infra-red absorption and noticed by Coblentz[5], Strong[6] and Parodi[7]. The loading of the lattice by the chromium ions will give rise to a perturbation of the vibrational modes, and this would explain the fact that in fluorescence and absorption the lattice vibrations appear as diffuse bands and not as sharp lines.

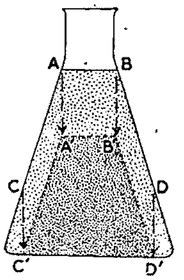
A Sedimentation Phenomenon

ONE of us (F. S.) was required some time ago to consider a proposed sedimentation apparatus for particle-size analysis, in which, for reasons beyond the scope of this note, the sedimentation vessel was to be a conical flask. Assuming the motion of each particle to be one of vertical descent, it was shown that an unstable condition would ensue. Suppose time has elapsed for particles of a specified size to fall from AB to $A'B'$. At this moment, no particle greater than the specified size will be above the surface $C'A'B'D'$, and the suspension within this region will have a higher specific gravity than the remainder. It was clear, therefore, that some flow of the suspension must occur and that the use of a conical flask would introduce an additional complication into the already difficult problem of particle size analysis.



Recently, one of us (R. J.) was shown a phenomenon which occurred after an aqueous suspension of potters' bone was shaken in a conical flask, and recognized it as connected with the above problem. When the flask was allowed to stand, normal settling commenced ; but after a few moments, alternating layers of clear and cloudy liquid appeared to be moving up the sides of the flask. This upward movement is evidently one phase of the readjustment which theoretical consideration requires, but it occurs rhythmically and not as a steady flow.

A similar effect has been observed with straight-sided vessels slightly tilted, suggesting that, when using such vessels, care in the vertical setting of the apparatus is of importance.

Technique of the Analysis of Variance

The analysis of variance technique originally devised by Prof. R. A. Fisher for the interpretation of agricultural experiments concerned the case of equal frequencies in the sub-classes. Prof. Fisher himself extended his technique to the case of unequal frequencies[1], when only the effect of one single variable was under examination.

The more general case of unequal frequencies in the sub-classes and more than one variable was dealt with by Brandt[2] and Yates[3], the latter introducing constants fitted by the method of least squares. The analyses already mentioned are special cases of the results produced by this method.

The methods appropriate to the two simple cases can be developed by using orthogonal polynomials, but this is not possible in the general case. However, if the frequencies n_{ij}, say, are such that they can be separated into two factors $u_i v_j$, say, then orthogonal polynomials can again be constructed.

So far as I am aware, it has never been pointed out that this method is not equivalent to that of fitting constants, except in the two special cases mentioned earlier. For example, if two variables with two values each are considered, then the method of fitting constants leads to

$$(x_{11}+x_{12}-x_{21}-x_{22})^2\Big/\left(\frac{1}{n_{11}}+\frac{1}{n_{12}}+\frac{1}{n_{21}}+\frac{1}{n_{22}}\right),$$

and that of proportionate frequencies to

$$\left(\frac{n_{11}x_{11}+n_{12}x_{12}}{n_{11}+n_{12}}-\frac{n_{21}x_{21}+n_{22}x_{22}}{n_{21}+n_{22}}\right)^2\Big/\left(\frac{1}{n_{11}+n_{12}}+\frac{1}{n_{21}+n_{22}}\right),$$

for the measure of the effect of the first variable.

It appears that different definitions of effects and interactions are implied by the two methods. This is logically unsatisfactory, since the definition of an effect or of an interaction should not depend on whether the frequencies are noticed to be such that a change in the definition leads to easier computations. The method of fitting constants should therefore always be accepted as the only legitimate one.

A detailed analysis, showing also that the case of proportionate frequencies is unique in making the introduction of orthogonal polynomials possible, will appear elsewhere.

Significance of Multiple Innervation of Cutaneous Pain 'Spots' in Relation to the Quality of Pain Sensibility

If a sphygmomanometer cuff is inflated at a pressure above systolic blood pressure on a human limb, a progressive loss of cutaneous sensibility occurs peripheral to the cuff. The work of Lewis, Pickering and Rothschild[1] in this connexion has been repeated and amplified. These authors describe a regularly ascending 'centripetal paralysis', and attribute this mode of spread to an increasing susceptibility of individual nerve fibres to the effects of pressure as they are traced proximally from the periphery. We have been unable to confirm any such regular centripetal spread of sensory loss. It has been found that, in the territory of any given nerve, loss of sensibility commences in different sites, not only in different subjects, but also in repeated experiments in the same subject, and spreads irregularly rather than centripetally. Indeed, in several instances an almost regular centrifugal spread has been observed.

If the hypothesis of Lewis *et al.* is correct, and individual nerve fibres do indeed become more susceptible to pressure the more proximally they are traced, then sensory paralysis should appear more quickly the more proximally the compressing cuff is situated on the limb. It is certainly the case that sensory loss occurs more quickly when the cuff is on the upper arm than when it is on the forearm. The evidence available, however, indicates that, owing to anatomical factors, pressure is transmitted more effectively to the underlying nerves when the cuff is is any position on the upper arm than when it encircles the forearm. Thus the observed difference between upper arm compressions and forearm compressions can be explained on purely mechanical grounds[2]. Direct evidence that there is no such sensitivity 'gradient', as suggested by Lewis *et al.*, may be obtained by altering the position of the compressing cuff on the *upper arm*. It is then found that, whatever the position of the cuff, no difference can be observed in the time of onset of sensory paralysis.

Lewis *et al.* attribute the order of loss of the various sensory modalities in any skin area to a differing susceptibility of nerve fibres of large and small diameters. Our observations show that this hypothesis is inadequate to explain the results in detail. The manner in which any modality is lost appears to be fairly characteristic. Subjectively, there is first an alteration in the quality of the sensation, then prolongation of the response followed by delay in appreciation, and, finally, patchy loss of sensibility.

Our attention has been directed particularly to the alteration in the quality of pain sensibility which precedes the onset of analgesia. This altered quality appears to resemble very closely the unpleasant pain which can be elicited from certain cutaneous scars, and also from skin at the borders of areas which have either been recently denervated or are in the course of sensory recovery.

Sensory tests have been carried out in several such cases, and the areas of skin concerned have afterwards been examined histologically after vital staining with methylene blue. It was found that, in all cases where pain of an unpleasant quality could be aroused, the nerve nets and terminals subserving pain were invariably isolated from their neighbours, in contrast to the interweaving which normally obtains. In parenthesis, it may be remarked that such alterations in the peripheral pain network appear to be without effect on the threshold of pain sensibility, which was found to be correlated with abnormalities in the morphology of the endings. The lowest thresholds occurred when the subjacent pain fibres were surmounted by growth cones ending just beneath the basal layer of the epidermis.

Direct stimulation of pain fibres in a human digital nerve has shown conclusively that such fibres obey the 'all or none' law. It follows that no modification of the characteristics of the stimulus applied to a single pain fibre will give rise to any change in the quality of the sensation perceived. Taken in conjunction with the histological observations, this observation suggests that changes in quality are due to alteration of the number and peripheral pattern of the fibres involved in the conduction of impulses arising from a given stimulus. The alteration in quality of pain sensibility which occurs during compression of the arm is in strong support of the above hypothesis. The pain fibres do not all simultaneously cease to conduct, and there is, therefore, a period during which there is a progressive reduction in the number of active fibres proceeding from a given area, and also an alteration in the peripheral pattern of innervation. It is precisely during this period that alteration in the quality of pain sensibility occurs, and it is difficult to escape the conclusion that the subjective change is due to this process.

Further work along these lines is in progress, and it is hoped shortly to publish results in detail.

British Folliculinidæ (Ciliata, Heterotricha)

DAS[1] has recently reported the occurrence at Cullercoats of two species of Folliculinidæ hitherto unrecorded for Great Britain, namely, *Folliculinopsis producta* Wright and *Folliculina simplex* Dons. He stated that only three other species have been recorded from Great Britain: *F. ampulla* Müller (Plymouth and Port Erin), *F. elegans* Clap and Lach. (Port Erin), and *Parafolliculina hirundo* Kent (Channel Islands).

To this list can be added[2] *Folliculina viridis* Wright, which, three years ago, during an intensive study of a rock pool in Langland Bay, Swansea, I found attached in some numbers to the fronds of *Corallina officinalis*. *F. viridis* is easily confused with *F. elegans*; but the former can be distinguished[3] by its smaller size and yellow-green colour. The overall length of my specimens (fully extended) never exceeded 400 μ.

Last year, while examining the fauna associated with *Porcellana platycheles* in Langland Bay, Swansea, I found the upper surface of the carapace and legs liberally encrusted with the (mostly) empty tubes of *Folliculina*. 310 tubes were counted on one crab, 128 of these being on the carapace. The dimensions and shape of the tubes, and absence of green colour in the living organisms, accord with the description given by Faure-Fremiet[3] for *F. elegans*.

Erythrean Fishes on the Mediterranean Coast of Palestine

THE presence of fishes of Erythrean origin in the Levant has been observed by several authors[1-6]. It has also been stated that these fishes must have traversed the Suez Canal and settled more or less finally in the Mediterranean. As this process of immigration of fishes into an entirely distinct region is going on continually, it may be of interest to list briefly those species which have been collected by workers of the Hebrew University and have so far been identified.

Atherina pinguis Lac.[1]
Hemiramphus far (Forsk.)[4]
Cyprinodon dispar (Rüpp.)[5]
Therapon jarbua (Forsk.)
Apogon tæniatus C.V.
Holocentrum rubrum (Forsk.)
Mulloides auriflamma (Forsk.)
Teuthis sigana Gthr.[2,3,4,6]
Platycephalus sp.
Monacanthus setifer Benn.[2-4]

Four of the ten species listed here were mentioned by previous authors as captured in Palestinian or Syrian coastal waters. The remaining six have—so far as we are aware—not been recorded from Palestine or Syria as yet.

A discussion of the data published in this note will be given elsewhere.

X-RAY CRYSTALLOGRAPHY

THE 1947 Conference of the X-ray Analysis Group of the Institute of Physics was held in the Royal Institution, London, on April 22 and 23. The first day was devoted to papers and discussion on the training of X-ray crystallographers for science and industry, and the second to descriptions of new techniques and results of X-ray analysis. The annual meeting of the Group was also held on the first day, and an evening lecture was given by Mr. H. P. Rooksby on "The Technique of X-ray Powder Photography" (see p. 7 of this issue).

It is impossible to give more in these notes than a very brief summary of the major contributions to the Conference. A fuller report will be published in the *Journal of Scientific Instruments*.

X-Ray Crystallographers in Industry

It became clear in the course of the two papers on this subject, and the discussion that followed, that there was general agreement on several interesting points. First, the demand for trained men still exceeds the supply, largely owing to a bottleneck in training; one way out of this difficulty, of which use has been made, is to send men already in industrial laboratories for short courses of training. This has the advantage that the workers are already acquainted with problems they will have to tackle, but the disadvantage that they cannot be spared for a length of time really adequate for training. Secondly, it was emphasized that a good X-ray analyst must have as broad a knowledge as possible of other sciences and techniques, in order to be able properly to assess the applications and limitations of his own technique.

Mr. D. A. Oliver suggested that a series of specialized monographs covering the whole theoretical and practical field would be useful to industrial X-ray crystallographers. He was of the opinion that, owing to general understaffing, industrial laboratories cannot usually offer much in the way of training apart from that in routine work, and that the present solution is that industry must assist in the training of research personnel by direct or indirect support of research in university departments.

Dr. L. Mullins gave details of a short course in X-ray crystallography given at Messrs. Kodak, Ltd., for industrial research personnel. Practical work includes the tackling of problems likely to arise in industry.

In the discussion, Sir Lawrence Bragg suggested that an appointments board in association with the X-ray Analysis Group might assist in the recruiting of X-ray crystallographers for industry. Mr. H. P. Rooksby was of the opinion that an industrial worker should be able to tackle fundamental problems, for which, however, a short course is not sufficient preparation. He also believed that those undergoing academic training would benefit by a period of apprenticeship in industry. Dr. W. A. Wooster agreed that work of a fundamental nature should be carried out in industry and suggested that research could usefully be divided into three types: (1) fundamental; (2) semi-fundamental; (3) technical. Dr. G. A. Jeffrey suggested that research organisations, when taking on university-trained men in order to start up an X-ray crystallography department, should take men from two or more university departments in order to ensure wide application of the technique.

Training of X-Ray Crystallographers in Polytechnics and Universities

The training of post-graduate chemistry students was discussed by Prof. E. G. Cox. This starts, in most universities, at a very elementary level, which is offset by a knowledge of the importance of the results of X-ray analysis to chemical problems. It is important to build on this by giving a man a research topic from the outset, which will encourage him both to acquire the necessary X-ray technique and also to widen his chemical horizons. Some formal instruction is considered necessary, covering crystal optics as well as X-ray analysis. Instruction in the latter is mainly concerned with structure analysis from single crystals, and here it is particularly important to find a suitable compromise between spending a great deal of time on learning to make and use equipment and do calculations, and becoming merely a machine-operator. To avoid the danger of becoming narrow-minded specialists, colloquia, visits to other workers, etc., are all important, but most important of all is the maintenance of the proper atmosphere in the laboratory.

The next speaker was Dr. H. M. Powell, who described the teaching in crystallography offered to students in chemistry at Oxford. It is realized that courses of two different types have to be provided: (*a*) for chemistry students generally, who need an outline knowledge of X-ray methods and their possibilities; and (*b*) for those intending to specialize in this work. Details of courses intended to meet this need were given, and stress was laid on the Oxford system of a graduate's fourth year of study, when a one-year research problem is tackled, sometimes leading on to further work.

Mr. F. Y. Poynton described how, in spite of all the difficulties of evening-class work, successful courses on the technical applications of X-ray diffraction had been run during the last few years, fitting into the general teaching of the Department of Applied Physics of the Northampton Polytechnic. The support of neighbouring industrial organisations had encouraged them to start recently a more detailed course for technicians beginning to use X-ray methods.

Dr. W. H. Taylor gave an account of the arrangements for teaching X-ray crystallography in Cambridge. He described the arrangements for Parts 1 and 2 of the Natural Sciences Tripos, and, leaving the Part 1 teaching to be described later by Dr. W. A. Wooster, went on to explain in detail the teaching for Part 2 students in chemistry, metallurgy and physics. Recognizing the two divisions of students mentioned by Dr. Powell, he showed how the content of each course is adapted to the needs and interests of each class of student and gave details of the practical work offered. He went on to describe the post-graduate work, explaining the advantages to the general outlook of students of the wide range of research, extra-mural, and administrative problems undertaken in the Cavendish Laboratory.

Dr. W. A. Wooster gave an account of the teaching of X-ray crystallography provided in the mineralogy course for Part 1 of the Natural Sciences Tripos at Cambridge. Emphasis was laid on the carefully prepared demonstrations and practical work and on the thoroughness of the teaching of the elementary ground-work, coupled with the Cambridge system of 'supervision' or private tuition. Dr. Wooster said that his Department would be pleased to try to help other people setting up similar courses by supplying photographs, etc., for demonstrations. He concluded by describing the content of an advanced course which he would like to see established.

Dr. R. C. Evans described the Cambridge Summer Schools in X-ray analysis which had been run for a fortnight each summer for the last four years. He gave details of the content of the course, explaining the importance attached to fundamental principles and the practical work undertaken by the students. In the subsequent discussion, Miss O. Weisz asked whether the material of the Cambridge Summer School could be published. Dr. Evans said that only photographs, etc., were yet available, and Dr. Lipson said that he hoped soon, in conjunction with Dr. Wooster and Dr. Henry, to publish a book based on the Summer Schools.

Further discussion brought out the advantages of both advanced and 'refresher' courses, though some speakers doubted whether research workers could spare the time required for these.

Dr. A. Taylor directed attention to the difficulties under which many technical colleges are operating, but Mr. N. Tunstall explained that the Ministry of Education is well aware of the position and is making considerable progress towards its improvement.

New Methods and Results of X-Ray Analysis

Investigations of the structure of the related minerals kaolinite, halloysite and fire-clays were described by Dr. G. W. Brindley. The study of kaolinite using high-resolution powder cameras showed that the unit cell is triclinic, not monoclinic as had been previously reported. The cell contains one unit of the silicate layer structure, and the way in which the layers are packed can be decided unambiguously. The powder patterns of halloysite and meta-halloysite show bands as well as sharp lines, which indicate almost complete disorder as regards the orientation of the layers. Heat-treated halloysite loses water and the layers collapse to form meta-halloysite; in the latter the layer spacing is still greater than in kaolinite, indicating that some water may still be trapped between layers. The state of crystallization of the kaolin mineral in fire-clays is intermediate between that of kaolinite and halloysite.

Mr. C. W. Bunn discussed investigations of the structurally similar (6, 6) and (6, 10) nylons or polyamides. Squeezing the fibres causes the orientations of the crystals to simulate twinning, and from these specimens it is possible to determine the triclinic unit cell, and work out the atomic positions by trial and error. It has been found that the chain molecules, which have a planar zigzag configuration, are linked by hydrogen bonds to form sheets. The sheets can pack together in two ways to form either α-crystals which have a one-molecule triclinic cell, or β-crystals which have a two-molecule triclinic cell. However, streaks which appear on most fibre photographs indicate a certain degree of random changeover from α- to β-type of packing.

Dr. W. Cochran, in his paper on sucrose, pointed out that it is one of the few comparatively simple organic compounds for which the accepted stereochemical formula has never been confirmed by chemical synthesis. For this reason X-ray analysis of its structure has been attempted, but so far with no success. However, the structures of isomorphous addition compounds with sodium bromide and chloride have been completely solved by two-dimensional Fourier methods, and results indicate that the sucrose molecule can be described as 1-α-glucopyranose-2-β-fructofuranose. The accuracy of the analysis was judged by the agreement between observed and calculated electron density distributions.

Mrs. Hodgkin gave a general account of the investigation of the structure of penicillin, and paid tribute to all those who had assisted in this work. Before X-ray work started, the chemists had proposed several possible formulæ, including (1) 'oxazolone', (2) 'β-lactam', (3) 'tricyclic'. X-ray analysis began on the sodium benzyl salt, but no progress was made with this. It was, however, possible to find the atomic positions of the alkali atoms and also the sulphur atom in the potassium and rubidium salts. Meanwhile, Mr. Bunn tried the 'fly's-eye' technique on an 'oxazolone' structure, at that time favoured by chemists, for the sodium salt, and succeeded in getting a *b* electron-density projection which was partially correct. The *b* projections for all three salts were re-examined and a related set of peaks found in all of them which was assumed to represent the molecule. After that the work was comparatively straightforward, and a three-dimensional synthesis proved the molecule to have the 'β-lactam' structure. Mr. C. W. Bunn described how he had used the 'fly's-eye' technique in conjunction with Bragg–Lipson structure factor graphs, and also a new method arising out of the latter for refining atomic positions.

In the course of the discussion which followed, Dr. H. Lipson said that he believed that comparison of observed and calculated intensities is the only satisfactory method of checking the accuracy of a structure, and Prof. E. G. Cox thought that the factor

$$\frac{\Sigma(F_{\text{obs}}-F_{\text{calc}})}{\Sigma F_{\text{obs}}}$$

provides the most satisfactory check now available; although, as Mrs. Hodgkin pointed out, it is not completely reliable.

New Industrial Techniques and Results

The afternoon session was opened by Dr. J. Bailey, who gave examples of the application of X-ray crystallographic equipment to the solution of technical difficulties in metallurgical production.

Dr. T. Ll. Richards illustrated some metallurgical applications of the stereographic projection, including an analysis of the mechanism of recrystallization in cold-rolled 70/30 brass.

Dr. H. D. Megaw, giving the first of several papers on ferro-electric compounds, described these as having an abnormally high permittivity, analogous to the high permeability of ferromagnetic materials. Of the perovskite-type group of compounds, barium titanate alone shows a distortion of the ideal cubic structure that is not compatible with Goldschmidt's principles. Barium titanate shows a reversible second-order transition at c. 120° C. to the ideal cubic form, and there are indications that there may be another transition at a low temperature. The transition from the cubic form is accompanied by characteristic multiple twinning.

Mr. M. J. Harwood described further work on the temperature variations of the barium titanate structure. He directed attention to the co-existence of both cubic and tetragonal phases in the region 120–125° C. Showing curves for the variation of cell dimensions of each phase with temperature, he explained the details by assuming that the lattice of the new phase is at first built on that of the old, and that the stresses thus set up increase until they are relieved by the formation of the new phase as a separate structure.

Mr. H. F. Kay described some optical work on crystals of barium titanate which he had prepared from a melt. He had observed domains which were truly single-crystal, and had followed the changes occurring at the high-temperature transition and also at and below 0° C.

Dr. L. A. Thomas described how Wooster's method of removing the Dauphiné (or 'electrical') twinning of quartz by applied heat and stress, although in general effective, had in some cases proved unsuccessful. Instead of the twin boundaries being removed, the twinned areas may show regions of persistence which can be correlated to some extent with the darkening response to irradiation with X-rays.

Mr. H. S. Peiser discussed the determination of the amorphous : crystalline ratio in polythenes. Working to a standardized procedure, it is possible, by microphotometric intensity measurements of the amorphous and crystalline X-ray patterns, to compare the ratios for different samples to an accuracy of ± 3 per cent.

Dr. C. J. Brown described some of the organic structure determinations carried out in his laboratory. Anthranilic acid, sodium naphthionate, acetanilide, and the new synthetic fibre 'terylene', were among the structures described.

Dr. A. F. Wells directed attention to the increasing tendency of chemists to use the results of X-ray crystallography in an insufficiently critical manner, and pointed out the responsibility which this places on the X-ray worker.

Dr. W. J. Wrazej gave some results on the structure of retained austenite in plain carbon steels, which indicated that it should be regarded as a face-centred tetragonally distorted structure rather than face-centred cubic.

In the discussion which followed these papers, many points in connexion with the barium titanate structure were raised, it being evident that the mechanism of transition from the tetragonal to the cubic phase is still very imperfectly understood.

Annual General Meeting of the X-Ray Analysis Group

In his report as chairman of the X-ray Analysis Group of the Institute of Physics, Sir Lawrence Bragg reviewed the previous very successful year and described the steadily widening activities of the Group. Sir Lawrence now retires from the office of chairman, and Mr. D. A. Oliver (director of research, B.S.A. Group of Companies) succeeds him. It was agreed to request the Board of the Institute of Physics to approve the creation of the office of vice-chairman, and Dr. W. H. Taylor (Crystallographic Laboratory, Cavendish Laboratory, Cambridge) was elected. Mr. J. N. Kellar (Crystallographic Laboratory, Cavendish Laboratory, Cambridge) was elected honorary secretary in succession to Dr. F. A. Bannister. Dr. H. Lipson, Mr. H. P. Rooksby and Dr. A. J. C. Wilson retired from the Committee, and Dr. R. C. Evans, Dr. T. Ll. Richards, Prof. J. M. Robertson and Prof. W. T. Astbury were elected, the last subject to the Board of the Institute agreeing to augment the membership of the Committee by one.

The business of the meeting was followed by reports, given by Dr. W. H. Taylor, Dr. R. C. Evans and Dr. F. A. Bannister, on the work of the equipment panels set up in the latter part of 1946. The Fourier Service Panel has concluded that the demand for a central calculating service is not large enough to justify setting up a special organisation, and those requiring assistance can apply direct to Dr. L. J. Comrie's organisation. New and improved Beevers–Lipson strips are being prepared. The X-ray Tube Panel, having made a general inquiry of users in Great Britain, has prepared a user specification for an 'ideal' demountable hot-cathode X-ray tube, but is taking no action in this matter beyond passing certain recommendations for improvement to the Raymax and Hilger sets to the appropriate firms. Specifications for moving anode and sealed-off tubes are being prepared. The Single Crystal Camera Panel is proceeding with a specification for a Weissenberg-type camera. The Powder Camera Panel is proceeding to design and prepare prototypes of a high-temperature camera, with the help of Mr. Oliver's organisation. Dr. W. H. Taylor announced that it is hoped to receive, through the Ministry of Supply, a number of sealed-off Philips tubes from Germany to fill the gap before tubes can be produced in Britain. Panels to deal with crystal structure models and miscellaneous equipment have also been set up.

J. N. Kellar

PRODUCTION OF ANTIBIOTICS BY *FUSARIA*

By A. H. COOK, S. F. COX, T. H. FARMER
AND
M. S. LACEY
Imperial College of Science and Technology, London

Earlier communications[1,2,3] described the production of an antibiotic pigment, javanicin, by *Fusarium javanicum*, and other *Fusaria* were also observed[1] to give rise to antibiotic metabolism solutions. So far, the examination of twenty-two *Fusarium* strains has revealed a frequent property of this kind; for convenience the moulds may be divided into groups according to the kind of activity exhibited by the crude culture fluids.

Group I, equally active against *Mycobacterium phlei* and *Staphylococcus aureus*: *F. javanicum*, *F.*6, *F.*64 (*F* numbers refer to strains which are as yet unidentified).

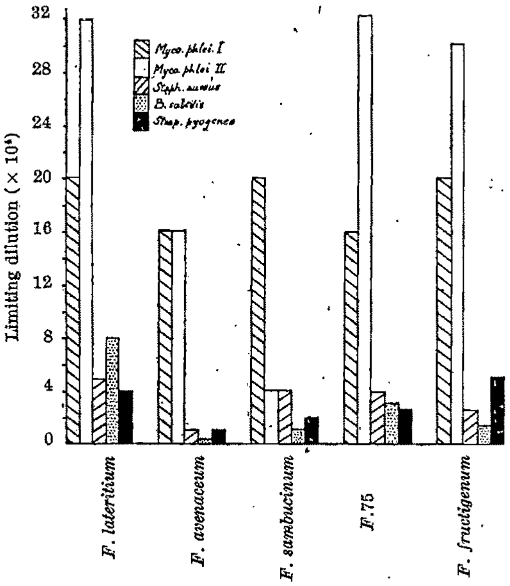
Group II, more active against *Myco. phlei* than against *Staph. aureus*: *F. lateritium*, *F. avenaceum*, *F. sambucinum*, *F. dianthii*, *F. fructigenum*, *F.*63, *F.*75 (probably a further strain of *F. lateritium*).

Group III, active against *Myco. phlei*, inactive against *Staph. aureus*: *F. culmorum* (Str. 61), *F.*72, *F.*91, *F.*101.

Group IV, inactive against both *Myco. phlei* and *Staph. aureus*: *F. oxysporum cubense*, *F. culmorum* (2nd strain), *F. cœruleum*, *F.*8, *F.*10, *F.*26, *F.*73, *F.*88.

Clearly this classification may depend on the cultural conditions employed, and it would in any event be less significant if the varying activities were merely due to varying proportions of two antibiotics or classes of antibiotics. Closer examination, however, has afforded chemical evidence which suggests that this division may reflect a more fundamental biochemical grouping.

The antibiotics produced by *F. lateritium*, *F. avenaceum*, *F. fructigenum*, *F. sambucinum* and *F.*75 (probably also a strain of *F. lateritium*) (Group II above) under selected conditions have now all been isolated in pure crystalline state. Excepting the



product of *F. fructigenum*, it is believed that under the culture conditions employed these new compounds represent the whole of the antibacterial activity present in the crude metabolism solutions. Naming them conventionally according to the species from which they are derived (that from *F*.75 being provisionally termed lateritiin-II) these compounds are quite distinct, the melting point of a mixture of any two being depressed: Lateritiin-I, $C_{26}H_{46}O_7N_2$, m.p. 121–122°; lateritiin-II, $C_{26}H_{46}O_7N_2$, m.p. 125°; avenacein, $C_{25}H_{44}O_7N_2$, m.p. 139°; fructigenin, $C_{26}H_{44-46}O_7N_2$, m.p. 129°; sambucinin, $C_{24}H_{42}O_7N_2$, m.p. 85–86°. These formulæ are regarded as subject to some revision of detail, though each is based on repeated concordant analyses. The compounds are also distinct in their antibacterial properties, as appears from the differing 'bacterial spectra' in the accompanying graph.

On the other hand, the compounds are so similar in chemical behaviour as to leave no doubt that they owe their biological activity to similar structural features. They are colourless, optically active, neutral, and sparingly soluble in water, but very soluble in organic solutions including light petroleum. All are stable to mineral acids under ordinary conditions, and to heat; indeed, lateritiin-I could be distilled *in vacuo* without chemical change occurring. However, all are very unstable to alkali, so that all antibacterial activity is irreversibly lost in solution at *p*H = 10–11 at room temperature after 18 hours. During this inactivation approximately two acid groupings per molecule are produced but disappear again, possibly by lactonization, when attempts are made to isolate the primary inactivation product. The group of compounds is otherwise notable for its lack of easily recognizable structural features. Thus avenacein contains no acidic, basic, carbonyl or alkoxy groups, nor any active hydrogen atoms detectable by the usual means. It does, however, contain two N-methyl and four C-methyl groups. When the compounds are heated with concentrated hydrochloric or hydrobromic acid at 120°, they are degraded to optically active crystalline bases which contain all the nitrogen present in the antibiotics. In addition, each of the antibiotics gives rise to the same crystalline acid, $C_5H_{10}O_3$; in the case of lateritiin-I the yield approaches that corresponding to the formation of two molecules of acid. The latter has been completely identified as the optically active α-hydroxy*iso*valeric acid corresponding to *d*(-)valine. To the best of our knowledge this acid has not previously been obtained directly from any natural source. It is interesting to note its correspondence with the amino-acid and particularly its retention of optical activity, the configuration being the 'unnatural' one.

Attention was specially directed to these antibiotics because of their action against *Myco. phlei* and possibly, therefore, against *Myco. tuberculosis*. Tests with lateritiin-I against three strains of tubercle demonstrated *in vitro* inhibitions at limiting dilutions of 1 : 160,000–1 : 640,000, indicating a high activity. Mouse experiments pointed to relatively low toxicity, at least by intraperitoneal administration. We are indebted to Drs. P. D'Arcy Hart and R. E. Glover (National Institute for Medical Research) for these results, but any therapeutic possibilities remain largely to be explored.

It has been noted that these *Fusarium* antibiotics are best produced when the mould is in a somewhat metabolically degenerate state. Perhaps such antibiotics are normal but mostly transient metabolic products, which only accumulate in sufficient quantities to permit of their recognition and isolation under abnormal culture conditions. It may perhaps be further envisaged that more deliberate induction of a moderately degenerate state may afford a degree of control over antibiotic production. Finally, it is worth noting that the above compounds appear to be products of an arrested metabolism exerting an antibiotic action on other presumably similar though obviously distinct metabolisms. The fact appears to offer perhaps profitable speculation on the mechanism of such manifestations of interference.

Full details of the above work will be published elsewhere. We are indebted to the Medical Research Council for assistance, and to Sir Ian Heilbron for his interest and encouragement.

NATIONAL INSTITUTE OF ECONOMIC AND SOCIAL RESEARCH

ANNUAL REPORT

THE annual report of the National Institute of Economic and Social Research for 1945–46 welcomes the recommendations of the Clapham Committee and particularly the declaration in that Report as to the national importance of the realistic studies to which the Institute has consistently devoted itself. Commenting on the new approach to economic problems illustrated by the elaboration of national income studies, the Institute's report points out that in Britain, in spite of sharp disagreement about particular methods and policies, there is a considerable measure of agreement about the ultimate goals of economic and social policy and the intellectual terms in which these problems may most profitably be set out, discussed and investigated. Moreover, the Institute has been able, through its Occasional Paper No. X, "A System of National Book-keeping:

Illustrated by the Experience of the Netherlands Economy", by Prof. J. B. D. Derkson, to make available to English readers some of the basic researches behind developments in economic planning in Holland, and it has also provided a meeting-place for the discussion of technical aspects of such problems between official representatives from Norway and Sweden and those engaged in similar work in Britain.

The immense tasks which face the advisers of Government call for a wealth of factual, quantitative information about the British economy and its development in the recent past which cannot be supplied entirely from official sources, and the contribution of the Institute in this field is of increasing importance. Of particular significance in this connexion, through its bearing on the structure and productivity of the national economy, is the inquiry on the "National Expenditure, Output and Income, 1920–38", which continued to be directed by Mr. Richard Stone. A first volume containing the results of the investigation into consumers' expenditure is already in the hands of the printers: as is a report on "Productivity, Prices and Distribution in Selected British Industries". A second report from the same investigation, "International Comparisons of Productivity in British and American Manufacturing Industry", is now being finally prepared for publication, while during the year work was started on the distribution inquiry with the aim at the first stage of building up a factual picture of the channels by which consumer goods passed from the manufacturer to the public in the immediate pre-war period. The second stage of the inquiry is concerned with the more difficult problem of the functions, stock turn, and cost and profit experience of different types of wholesaler and retailer. Late in 1945 a building inquiry was commenced, under Mr. I. Bowen, covering the structure and efficiency of the building industry, housing demand and the building cycle, and economic problems arising from new building techniques. Main attention is being given to the first topic, and it is hoped that a report on this part of the programme will be completed during 1947.

The work on capital formation and public authority expenditure has continued, attention so far having been concentrated on the current and capital expenditure of local authorities. The inquiry into disease mortality and its changing distribution has issued in a draft report "The Social Geography of Mortality in England and Wales, 1911–38"; but Dr. Kuczynski's study of post-war population problems has been suspended while the Royal Commission on Population is in session. The inquiry into advertising has been completed, and a report on "Statistics of Advertising" is to be published later. Miss P. M. Deane completed her Occasional Paper, "The Measurement of Colonial National Incomes: an Experiment", before taking up her field experiments as a Colonial research fellow in Africa. A joint exploratory committee with representatives of the Institute of Chartered Accountants has considered the field of work in which accountants and economists have a common interest, and it is hoped to publish later an agreed statement of its findings. Senior research fellowships were awarded during the year, under the scheme described in last year's report, to Mr. E. J. M. Buckatzsch for an inquiry into "Factors Affecting Income per Head in Towns and Areas in England and Wales, 1929–1939", to Miss K. Liepmann, for an inquiry into "The Extent and Composition of Labour Markets in Selected Areas in the South West", and Mr. H. G. Schenk's part-time fellowship has been extended to enable him to complete his inquiry into "European Romanticism and the Social Revolution, 1790–1830". The Register of Research in the Social Sciences for 1940 is being distributed as a confidential document. New Institute publications during the year are listed in the report.

SALMON MIGRATION AT SEA

THE Buckland Foundation Lecture was given by J. W. Menzies at the University of Liverpool, on May 28, Prof. J. H. Orton presiding. Taking for his subject "The Migrations of Salmon in the Sea", Mr. Menzies summarized the information learned from the experiments of marking salmon in Scottish, Norwegian, Baltic, and Canadian haunts, and suggested that European and Canadian salmon have a common feeding ground in the North Atlantic near Iceland, where a new marking station will probably be opened under international co-operation in a few years time. The only area where *Salmo salar* has been traced from the river of origin to its feeding ground in the sea and then back to the river as adult fish is the Baltic, where Swedish marking experiments showed that smolts left the northern Swedish and Finnish rivers in spring when only 5 in. long and reached the southern Baltic, 600–800 miles away, in October and November, when they weighed just over a pound after feeding; but they did not show evidence of passing out of this belt into the North Sea. Salmon apparently do not feed in the North Sea, or The Minch of western Scotland, or they would have been caught more often in the herring nets. The Swedish salmon feed in the southern Baltic for possibly up to two or three years before returning to their native rivers.

Salmon marked in the Gulf of St. Lawrence, and off the shores of Scotland and Norway, have shown two types of movements. In one they have been recovered after they have nearly completed their journey home again, when they remain off the river until a flood induces them to ascend. They cease feeding once they reach the coast, and if a drought keeps them there some weeks or months, they lose weight, a 15-lb. fish losing 2–3 lb. in a little more than two months while waiting to ascend the river; a 15-lb. fish lost 4 lb. in 67 days; a 12-lb. fish lost 2 lb. in two months. Only five marked fish were recovered more than ten miles from Thurso Bay, and marking showed a similar restricted movement in the inner Moray Firth; only six out of more than 400 strayed outside the outer limits of the Firth, and there were similar results from Canada and Norway.

Other salmon, particularly those marked off south-west Newfoundland, western Scotland and western Norway, made long journeys to the place of capture, the record being a St. Lawrence fish caught as a clean fish in sea nets 2,000 miles away up the Labrador coast, while from near the north of Norway an easterly migration has been traced to the River Petchora, the easterly limit in the distribution of *Salmo salar*. In both Canada and Scotland these long journeys have often been four or six hundred miles, and on the Norwegian coast 1,600 miles to the White Sea. Marked salmon have travelled between Scotland and Norway, but not across the Atlantic, so far as recoveries show; but all these fish seem to be going back to the river from which they came as smolts.

Marking not only indicates the length of migration, but also the speed, and the longer the migration the faster appears to be the speed, especially with Norwegian records, one of which was recovered 680 miles away in a little more than ten days, a speed of 62 miles per day. Adult salmon in the sea travel at a minimum rate of between ten and twenty-five miles a day.

Mr. Menzies suggested that the cause of the very poor salmon season of 1945 in Britain probably lay in feeding conditions at sea, not in fresh-water rivers, because in Iceland, Norway and Canada this was also a bad season. When swimming near the coast, salmon travel within 7 ft. of the surface; but although herring and sand-eels have been found in them, very little is known of their diet in the sea, and those caught near the shore were almost invariably empty.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, July 7—Wednesday, July 9

University of Bristol (at the H. H. Wills Physical Laboratory, Royal Fort, Bristol), at 9.30 a.m. and 2.45 p.m. each day.—Conference on "The Strength of Solids".

Monday, July 7—Thursday, July 10

Royal Society, Gassiot Sub-Committee B (at Burlington House, Piccadilly, London, W.1).—Conference on the "Emission Spectra of the Night Sky and Auroræ".

Monday, July 7

At 11 a.m.—Prof. S. Chapman, F.R.S.: Opening Address.

Monday, July 7—Saturday, July 12

Chemical Society, Society of Chemical Industry and Royal Institute of Chemistry, Edinburgh and East of Scotland Sections (at The University, St. Andrews).—Symposium on "Coal, Petroleum and their Newer Derivatives".

Tuesday, July 8

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. D. Rittenberg (Columbia University): "The Application of the Isotope Technique to some Biochemical Problems".*

Wednesday, July 9—Saturday, July 12

Society for Applied Bacteriology (at Reading).—Annual General Meeting and Paper Reading Conference.

Wednesday, July 9

At 8 p.m. (at St. Andrews Hall).—Annual General Meeting.

Thursday, July 10

At 10 a.m. (in the Zoology Lecture Theatre).—Symposium on "Water Bacteriology"; at 2.15 p.m.—Paper Reading Conference.

Friday, July 11

At 10 a.m.—Paper Reading Conference.

Thursday, July 10—Saturday, July 12

Institute of Physics, Manchester and District Branch (in the Physics Department, The University, Manchester).—Conference on "Applications of Radioactive Tracer Elements in Physics Research and Industry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Textile Technology, and a Lecturer in Mathematics—The Registrar, College of Technology and Commerce, The Newarke, Leicester (July 12).

Senior Assistant (with a good Honours degree) in the Department of Chemistry, a Lecturer in Pharmacy, a Lecturer (with a good Honours degree or its equivalent) in Mathematics, Senior Assistants (3) in (*a*) Design Section, (*b*) Production Engineering Section, (*c*) for Research and Experimental work, and Lecturers (2) for (*a*) Design Section, (*b*) Production Engineering Section, in the Department of Mechanical Engineering, Lecturers (2) in Electrical Engineering up to Higher National Certificate standard, and Lecturers (2) in (*a*) Carpentry and Joinery, (*b*) Plumbing and Sanitary Engineering, in the Department of Building and Structural Engineering—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (July 12).

Lecturer in Zoology and Chemistry—The Registrar, Merchant Venturers' Technical College, Bristol (July 12).

Lecturer in Physics—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (July 12).

Lecturer in Chemistry—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (July 14).

Lecturer in Mathematics in the United College—The Secretary, The University, St. Andrews (July 15).

Lecturer in Geology (Petrology and Mineralogy) in University College, Dundee—The Secretary, The University, St. Andrews (July 15).

Lecturer in Zoology to take charge of the Gatty Marine Laboratory—The Secretary, The University, St. Andrews (July 15).

Lecturer in Physics, and a Lecturer in Civil and Mechanical Engineering—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (July 19).

Lecturer, and an Assistant Lecturer, in Physics—The Secretary, King's College, Strand, London, W.C.2 (July 21).

Adviser in Agricultural Economics, a Senior Agricultural Economist, and an Assistant Agricultural Economist—The Registrar, The University, Manchester 13 (July 26).

Lecturer in the Technical Department, for City and Guilds Telecommunications up to Grade 5—The Technical Officer, University College, Southampton (July 26).

Lecturer (Grade II) or Assistant Lecturer (Grade III) in Physics—The Registrar, University College, Southampton (July 26).

Lecturer in Philosophy in the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 30).

Dairy Officer in the Department of Agriculture and Lands, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (July 31).

Statistician in the office of the Town Clerk—The Town Clerk, Town Clerk's Office, Room 30B, Council House, Birmingham 1, endorsed 'Central Statistical Officer' (July 31).

Zoologists (4) with special experience of taxonomic work on (*a*) mammals, (*b*) fishes, (*c*) arachnida, and (*d*) mollusca, and Entomologists (4) with special experience of taxonomic work, at the British Museum (Natural History)—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1936 (July 31).

University Lecturer in Physics—The Secretary of the Appointments Committee, Faculty of Physics and Chemistry, Chemical Laboratory, Pembroke Street, Cambridge (July 31).

Lecturer in Pathology—The Registrar, The University, Sheffield (July 31).

Director of Research for the development of Rheumatism Treatment and Research, and a Research Fellow in the Surgery of Rheumatism—The Registrar, The University, Leeds (July 31).

Soil Biochemist, a Physical Chemist with experience in a colloid laboratory or used to X-ray technique, a Physical Chemist with experience in spectroscopic or polarographic techniques, a Soil Chemist with general soil experience, and a Soil Chemist with some training in botany as well as chemical experience, in the Soil Bureau, Wellington—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (August 1).

Junior Physico-chemist for bacteriological and virus research work—The Secretary, Inoculation Department, St. Mary's Hospital, Paddington, London, W.2 (August 1).

Assistant Lecturer in the Department of Embryology—The Secretary, University College London, Gower Street, London, W.C.1 (August 1).

Senior Research Officers (2), Research Officers (12), Assistant Research Officers (6), and Research Assistants (7), in the Ministry of Town and Country Planning—The Secretary, Ministry of Town and Country Planning, 32 St. James's Square, London, S.W.1 (August 15).

Statistician—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks.

Game Ranger (with a science degree, preferably in zoology) in Tanganyika Territory—The Director of Recruitment (Colonial Service), Colonial Office, 15 Victoria Street, London, S.W.1.

Research Student in Soil Science—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen.

Librarian—The Assistant Secretary, Royal Anthropological Institute, 21 Bedford Square, London, W.C.1.

Lecturer (Grade III) in the Department of Chemistry—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4.

Research Chemist—The Director, Motor Industry Research Association, Great West Road, Brentford, Middx.

Director of Research—The Chairman, British Welding Research Association, 29 Park Crescent, London, W.1, endorsed 'Director'.

Research Engineer for research on machinery used in the clay industry—The Director of Research, British Pottery Research Association, Queens Road, Penkhull, Stoke-on-Trent.

Technician for Biochemical Department—The Bursar, The University, Sheffield 10.

Senior Assistant, and a Lecturer, in the Department of Electrical Engineering—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18.

Lecturer in Telecommunications, with specialist knowledge in Radio Engineering—The Principal, Wimbledon Technical College, Gladstone Road, London, S.W.19.

TRAINING FOR MANAGEMENT

SINCE the Urwick Committee was appointed in October 1945, "To advise the Minister of Education on educational facilities required for management in industry and commerce, with particular reference to the steps to be taken in regard to the organisation of studies, bearing in mind the various requirements of professional organisations and the need for their co-ordination", the importance of efficient management has been repeatedly stressed in relation to the productive effort of Great Britain, and the Government has already accepted the recommendation of the Baillieu Committee for the establishment of a British Institute of Management. The eighth International Conference on Management, at which Great Britain was represented, has recently been held in Stockholm. The Urwick Committee reported in August 1946, but after a meeting with representatives of the professional bodies concerned with the part-time study of management in technical and commercial colleges, certain amendments to the report were made by the Committee. The amended report now published* is not only approved by the Minister of Education, but also the institutions and associations represented at the meeting have agreed to do all in their power to implement its recommendations.

Such circumstances alone would give practical interest to the report, which not only contains a number of sensible recommendations on training for management, but also indicates some aspects of the problem which require further investigation. The Committee takes a wide view of management, which in this context it understands as all those activities involving responsibility for the work of others. It is pointed out, however, at the outset that no matter how good special courses of study at technical or commercial colleges may be, theoretical study alone cannot make a manager.

On this basis the Committee attempts to estimate the number of persons engaged in managerial functions at the present time. It has not been able to arrive at an accurate estimate as there are no figures later than the 1931 Census to serve as a basis ; but starting from these figures, and allowing for the considerable changes that have occurred since, the Committee computes that between 400,000 and 450,000 persons in Great Britain are so engaged at the present time. This is a considerable total, and although it is to be hoped that, as recommended by the Hankey Committee, the Higher Appointments Department of the Ministry of Labour and National Service and, as here suggested, the British Institute of Management, will obtain more accurate information in due course, the estimate can be used to arrive at an even more important figure from the point of view of training facilities—the approximate number of recruits each year.

Assuming that the working life of individuals discharging managerial functions is thirty-five years, the Urwick Committee estimates the annual intake as some 12,000 ; this is admittedly a rough guess, but one which indicates the magnitude of the problem. There are, of course, complications such as the wide variation in the ages at which individuals take up positions which are classed as managerial under the definition already given—the scientific worker himself provides a pertinent example. Dr. Vannevar Bush, in his recent report as president of the Carnegie Institution of Washington, referred to the duty of men of science to participate increasingly in the task of government by manning the boards and committees which are necessary to-day to provide scientific and technical advice. There are many other more specific administrative and managerial responsibilities which trained scientific men must accept if the business of government and industry alike is to be conducted efficiently; and yet, as the Percy Committee noted, not only is the highly trained technician often indisposed to accept such responsibility, but also he is often ignorant of the principles of industrial organisation and management. Admittedly much in this field can only be learnt from experience, but there is a body of knowledge in existence, awareness of which may greatly facilitate the process of learning.

---

* Ministry of Education. Education for Management : Management Subjects in Technical and Commercial Colleges. Report of a Special Committee appointed by the Minister of Education. Pp. 32. (London : H.M. Stationery Office, 1947.) 6*d*. net.

There is, of course, nothing new in the suggestion that management should be the subject of theoretical study; although management is still often regarded primarily as a matter of common sense and experience, and frequently knowledge of a particular branch of business is still the sole criterion of competence. In the last thirty years, since the work of F. W. Taylor and Henri Fayol became better known, a large body of knowledge bearing upon what Fayol described as the six main activities of management—forecasting, planning, organising, commanding, co-ordinating and controlling—has been built up, irrespective of the field of industry to which they are applied. Most people would probably agree with the Percy Committee that ignorance of the main findings of studies in these fields is a real handicap to men who would otherwise be highly qualified for administrative work. It is less certain that it is generally recognized, as the Urwick Report claims, that there is general ability to manage which can be made the subject of a recognized 'discipline' based on objective research: the Percy Committee, for example, appears to reserve its opinion on the subject and is at least dubious.

Examining the special character of this body of knowledge, the Urwick Committee points out that it is distinct from any detailed understanding either of the processes of the particular industry or of the various services and skills which are themselves indispensable tools for the conduct and regulation of a complex organisation. The Committee claims that such knowledge should enable its possessor to determine the immediate and the long-term objectives of the whole, or of any part of the undertaking, to judge readily the significance and the comparative importance of the varied advice which he receives, and to appreciate the contribution which the expert, whether as an individual or in combination with others, is able to make. It should also teach him how to use each contribution effectively, and to integrate these several abilities so as to ensure the most appropriate action. The technique of attaching to each factor its due weight and of making the necessary synthesis can in part be taught, even if its exercise is a matter of judgment in which personal capacity and experience are the essential factors.

Whether or not we admit the claim of management studies to be a scientific 'discipline', there are certain foundations upon which alone management can be taught. The Urwick Committee distinguishes these as of three types: an adequate standard of general education; knowledge of certain 'background' subjects which provide a basis for the study of management in any particular field; and certain 'tool' subjects, such as accounting, statistical method, production methods, work analysis and incentives of which the manager should possess a sufficient appreciation of their principles, processes and application to be able to direct skilled assistance effectively. The varied channels through which the individual approaches managerial responsibilities make it difficult, if not impossible, to provide a course of study which insists on any common background. Nor is it even a disadvantage to the nation that the pattern of recruitment, while changing considerably in the last twenty years, should be varied; and the Urwick Committee is right in insisting that no matter how comprehensive the national system of education, opportunities to obtain the higher posts in business should continue to be open to those whose training has been predominantly in the school of experience. The capacity for initiative and leadership is not solely, nor even mainly, a matter of intellectual quality, and no system of tests or competitive examinations, however careful and objective, is a fully satisfactory determinant of the power to discharge major responsibilities. It may, of course, be asked whether this could be determined by any system.

While, however, the Urwick Committee believes that managers in industry and commerce will continue to be recruited from four main groups, one of which would consist of those with initial scientific or technical qualifications (such as engineers, chemists or accountants), who find themselves increasingly occupied with managerial functions, it strongly deprecates the multiplicity of syllabuses both within the broad management field and within the fields of professional institutions conducting examinations including subsidiary management features. The major part of the report is indeed concerned with suggestions for the assimilation and development of courses, so as to relieve the embarrassment of education authorities and secure the most effective use of the limited supply of trained teachers.

The Urwick Committee recommends first that the professional institutions should accept the obligation to include in their syllabuses as large a common management content as possible, and confine specialized demands in this field to the essential minimum. Courses leading to qualifications in management should be limited to two stages. For the first, or intermediate, of these courses, all management professional institutions should adopt a common curriculum, and technical professional institutions should adapt any management requirements to this common curriculum, which would comprise an introduction to management, 'background' subjects and 'tool' subjects. For the second or final course, two types are suggested, intended for those who wish to qualify in some specialized field, or in general management, respectively. For the former the curriculum should be prescribed largely by the appropriate management professional institution; but for the latter the curriculum should be prescribed by the appropriate national authority. Suggested syllabuses for both intermediate and final courses are appended to the report, and it is recommended that both courses should lead to a qualifying examination. The final examination in specialized management should not be taken before the age of twenty-five, or in general management before the age of twenty-eight.

The Committee contemplates that such courses will be taken in the main as part-time studies. Although it suggests that the various courses should be spread over a number of years with appropriate intervals, and that a student should not be expected to devote more than two evenings a week to formal instruction during the technical college year, it is surprising at this stage to find support from such a source for evening classes. It will be recalled that the Percy Committee was most emphatic as to the unsuitability of evening study for the bulk of technical education in engineering, and the Urwick Committee appears to be unduly timid in urging that the study of management should be carried out in part-time day classes. It is still more surprising that the first recommendation in this field by the Percy Committee, that all students of technology, whether at the universities or colleges of technology, should be introduced to these subjects during the final year or two years of their undergraduate course, is not even mentioned.

For all that, the Urwick Report covers a much wider field than the earlier report on Training for Business Administration issued by the committee under the chairmanship of Sir Frank Newsom-Smith. The functions of the Administrative Staff College appear to lie outside the terms of reference of the Urwick Committee, although one might have expected some comment on the idea of the staff college and of refresher courses for those of mature years, particularly with reference to the final courses or diploma. The merits or demerits of an intensive full-time course of two or three months do not appear to have been considered.

Apart from this, the third section of the Urwick Report, which discusses some wider considerations, is sound and well-balanced and makes a number of important suggestions, particularly as regards work which might be undertaken by the British Institute of Management. The first of these arises out of the lack of comprehensive statistical information illustrating the national facilities currently available for education in management. It is recommended that the new institute should undertake an investigation of the national requirements of men competent to discharge managerial responsibilities, and that the various education departments should compile and publish annually comprehensive national statistics on the volume and distribution of educational facilities in management subjects in Great Britain, including details of the numbers of courses and of students attending them. Other bodies should co-operate so as to synchronize with and include in the official figure such activities as those of the Training Within Industry Scheme, the Business Training Scheme for ex-Servicemen and the work of the Administrative Staff College and of university departments.

The report also recommends that immediate steps be taken to secure an increase in the supply of trained teachers in management, both part-time and full-time. The former might be helped by the professional institutions maintaining, through their local organisations, a list of men and women willing to do part-time work, and by the education departments providing facilities for training such men and women in the methods of teaching. The report also welcomes the recommendation of the Percy Committee that at least one institution should be selected as a centre for post-graduate study of industrial administration. This, however, is regarded as insufficient, and it is suggested that the Regional Advisory Councils for Further Education which are being established should be asked to deal, as one of their first tasks, with the provision of opportunities for systematic higher education in this field, leading to recognized academic qualifications. It is recommended further that the British Institute of Management should have associated with it from the beginning an Advisory Council on Education for Management, representative of all those interests concerned with this matter. No comment is made on the poor quality of the present literature of the subject in Great Britain, as did the Percy Report, other than attributing the serious lack of original research and of suitable text-books largely to the dearth of suitable teachers of management. Finally, in commenting on the position in the United States, which is described in an appendix, the Committee recommends that a commission of inquiry should visit that country to report on the facilities for education in management there as compared with those provided in Great Britain.

Uhe Urwick Report may thus be welcomed by all who believe that it is no longer sufficient to appoint as managers those who have shown ability perhaps in some quite different field. If it makes no substantial contribution to the vexed question as to how best we can pick the outstanding administrator for the highest positions, it at least indicates how the level of management can be raised and our chances of picking such men increased. Moreover, the recommendations go some way towards facilitating a solution of that major problem of our time—the effective use of the expert in the task of administration whether in the industrial or the government sphere. Although the report has little or nothing to say about training for management within the Civil Service, it makes a real contribution to the practical task of unifying courses of training and securing the most effective use of our limited resources of trained teachers in this subject.

THERMODYNAMICS AND HUMANISM

Time and Thermodynamics

By A. R. Ubbelohde. Pp. vii+110. (London: Oxford University Press, 1947.) 6*s.* net.

THIS little book shows some confusion of aim. I do not think Prof. A. R. Ubbelohde decided clearly what kind of book he wanted to write. According to the preliminary chapter, his intention appears to have been to write on the wider human aspects of thermodynamics, to contribute to scientific humanism, which he defines as the unification of the specialized sciences from the point of view of their human interest. In this and in his explanations of the significance of entropy as providing a direction pointer for time, he is on fairly familiar ground, and though his treatment inevitably calls forth a comparison with the popular writings of Eddington, who covered similar territory with, one must say, considerably more force, he is both competent and interesting.

The body of the book is, however, a fairly straightforward explanation of the laws of thermodynamics, partly classical and partly statistical, which will undoubtedly be helpful to students of the physical sciences, since it will enable them to appreciate some of the more difficult parts of the subject. But the inquiring layman may be repelled by even simple algebra, and he will find the chapter on the second law, which does not differ in any essentials from that found in most text-books of thermodynamics, rather stiff going.

The discussion of the human significance of the laws of thermodynamics, being confined mainly to short chapters at the beginning and the end, is disappointing. Most readers looking for humanistic meanings will turn to the chapter on thermodynamics and life to see what the author has to say; but they will have some difficulty in determining what his attitude really is. He favours, without dogmatism, the very reasonable view that "living organisms are characterised thermodynamically not by any vital power of selection of individual molecules, but by the fact that the organism considered as a unit is continually effecting processes in which the entropy decreases, at the expense of rather greater compensating increases of entropy in the surroundings".

So far, good. Few readers will be inclined to disagree with the author when he explains that living things are entirely unique arrangements for effecting locally such 'disentropic' processes, and, quite unlike anything encountered in non-living matter. But what are we to make of the following: "Currently accepted terminology would describe human control over natural forces and human organisation of inanimate processes as intelligent. The organisation of similar processes within living organisms, which normally involves more complex integration than has yet been achieved through human inventiveness, must be the result of *analogous intelligent inventiveness*" (my italics)? It would be of interest to have this argument developed, though it is not particularly new (*vide* Paley's watch); but the author puts off his readers with the remark: "Full elaboration of the inventor analogy would not be possible without very greatly exceeding the scope of this book. The issues involved are profound."

If I understand it correctly, the argument is that although the chemical happenings in living organisms may be fully in accordance with the laws of thermodynamics, yet the existence of such extraordinarily complex arrangements for utilizing these laws to produce organisms capable of individual activities, and in many cases intelligence, involves something in addition.

Any fresh arguments for this view would be of great interest. What the author actually does is to mention certain lines of argument and dismiss them as outside the scope of the book. For example, he says, "A further point which may be mentioned, but which cannot be developed very far in this book, is that if the human intelligence is able to conceive (at least by negation) of conditions in which the laws of nature, such as the trend in entropy, are not obeyed, it cannot itself be wholly subject to these laws". Or again, "But there is no real promise of ever bridging the gap between the mechanism as a whole and the organism as a whole, through increased human skill. The nature of the difference between mechanism and organism cannot be further resolved without bringing in other considerations about life which lie outside the scope of this book." It is scarcely fair to the reader to raise such points and leave them up in the air. One cannot help wondering how much the author's final conclusion that "human living is part in entropy-time and part outside it" is based on the "other considerations".

I do not want to suggest that I think there are no other considerations which are worthy of attention. They have been stated with varying degrees of cogency and charm by poets and philosophers as well as some men of science. But Prof. Ubbelohde is shy of developing his argument in this direction. He reminds us of the Scotsman's remark to a lady who had been praising the English: "But hae ye ever been able to get one of them into a metapheesical argument?" He refuses to be drawn into metaphysical arguments; but does not mind supporting his point of view by referring to their existence. It is rather curious that he never mentions, though he may imply, the one inevitable teleological conclusion from the second law, that if the world as we know it is steadily running down, there must have been a winding up.

J. A. V. BUTLER

SCHOOL CERTIFICATE BIOLOGY

Essentials of Biology

An Introductory Text-Book for Secondary Schools. By W. F. Wheeler. Pp. xi+266+8 plates. (London: William Heinemann, Ltd., 1947.) 7*s.* 6*d.*

AS was indicated in *Nature* a short time ago (159, 147; 1947), in the teaching of biology a new movement is spreading through the schools, of considerable educational import, the object of which is to relate the biological sciences directly to human life and culture. This movement has proceeded farthest in the new modern schools, and with sixth-form classes in the grammar schools. In each of these cases the topics dealt with depend largely on the interests of the teacher and his class. With no examination restrictions, presentation may sometimes be amateurist and standards rather low; but, at any rate, links of understanding are being established between work in school and some issues in the outside world which are of major significance.

Compared with this, routine teaching of biology in the grammar schools has an academic flavour, with emphasis almost wholly on the 'essentials' of the subject, hinged as it is on the twin pillars of School and Higher School Certificate. Although the syllabuses for these examinations are gradually being altered in accordance with modern views, their present scope and outlook find clear reflexion in a new text-book of biology by W. F. Wheeler for the School Certificate. Judged by text-book standards, he has achieved a useful piece of work. Apart from minor slips of emphasis and fact, the subject-matter is sound, well set out upon the page and supplemented with many helpful diagrams and photographs. The practice of reproducing line drawings giving details not referred to in the text is, however, open to question, and so is that of including material considerably more advanced without indicating at what stage it will be required. The lot of the young pupil will not be made any easier by the involved language in which the subject-matter is expressed, for it is by no means simple English. As for presentation, the author has given special prominence to human anatomy and physiology, with a useful section on human reproduction. The rest of the book follows the type method of description, both for animals and plants, so that function follows structure, although towards the end there are short chapters on such subjects as the organism and its environment, growth and multiplication, and evolution and classification.

Yet, with its concentration on 'essentials', the book conveys a curious picture of the living world. It is for the most part a two-dimensional picture of morphological and histological details, each with its appropriate technical term duly emphasized in heavy print. It is a picture lacking in unity, purpose or emotional appeal, detached on one side from personal responses to the riches of wild Nature, and on the other from the interests and needs of man, whether material, social or philosophical. To points such as these Mr. Wheeler may justly reply that they do not fall within the syllabus. To that extent the School Certificate is in danger of leaving biological thought in a state of arrested adolescence. Are these 'essentials' really so necessary; and what is their educational significance? R. WEATHERALL

THE LINNEAN HERBARIUM

A Catalogue of the Linnean Herbarium

Compiled and annotated by Spencer Savage. Pp. xv + 225. (London: Linnean Society of London, 1945.) 40*s.* net.

THE Linnean Society of London has been well served by its historians and cataloguers. The late Dr. B. Daydon Jackson, general secretary from 1902 until 1926 and curator of the Linnean Collections during 1926–27, the late Lieut.-Colonel A. T. Gage, assistant secretary and librarian from 1924 until 1929, and Mr. S. Savage, the present assistant secretary and librarian, have been notable recorders of the history of the Society and have done much to make the Linnean collections serve their full purpose in taxonomy. Daydon Jackson published in 1907 (in the *Proceedings of the Linnean Society*) an article "On a Manuscript List of the Linnean Herbarium" to which was appended a "List of the Genera in the Linnean Herbarium". As a supplement to the *Proceedings* for the 124th Session, 1911–12, he published an "Index to the Linnean Herbarium". In both of these works there is much information of value to those wishing to consult the collections. Neither, however, is a catalogue even approximating in scope to that prepared by Mr. Savage.

The present work is not only a list of the specimens in the Linnean Herbarium but also "includes, with as much detail as was considered necessary, the inscriptions up to the time of Sir James Smith's death in 1828—i.e., before the Herbarium came into the Linnean Society's possession". The sequence of the Catalogue is the same as that of the Herbarium.

A great deal of trouble has been taken by Mr. Savage to interpret the various signs used by Linnæus. Six of these signs are of special importance since they probably indicate geographical areas from which the specimens were obtained. It is suggested that Linnæus's liking for brevity was linked with a certain amount of secrecy in dealing with Russian specimens, including those he obtained from Asiatic Russia.

Particularly difficult and time-consuming was the correct attribution of the eighteenth-century handwritings in the Linnean Herbarium. Most of the inscriptions are in Latin and in what is termed 'Italian cursive hand', which shows various national characteristics. The following national handwritings are recorded as present in the Herbarium: Italian, French, Dutch, Spanish and Portuguese, Swiss, Russian, German and Austrian, Swedish, and British. Much of what Mr. Savage has to say on these handwritings will be of value to biologists who have to read and interpret manuscripts and labels written in the eighteenth century. The difficulties of interpreting such handwritings are numerous. One learned Swede wrote three distinct handwritings—"a script hand for Swedish, an Italian cursive hand for Latin, and a form of Court hand for ceremonial occasions". Linnæus's own handwriting is often very difficult to read and deteriorated considerably in his later period. He more and more sacrificed legibility to speed and tended to omit portions of letters. In the present Catalogue are photographic reproductions of seventy-two specimens of handwriting, mostly about half size. These make a valuable and interesting series.

Naturally much of what Mr. Savage records has a bearing upon the sometimes difficult problem of the typification of Linnæus's species. He does not, however, enter into details. He records that "Linnæus 'wrote up' specimens, but by no means entirely, on a 'type specimen' basis. He *sometimes* wrote the species number only on an added sheet, but there are many instances where several sheets have been 'written up' by him." Examination of specimens in the Linnean Herbarium does not eliminate the need for a careful study of Linnæus's descriptions and of the synonyms cited by him. The existence at the British Museum (Natural History) of Clifford's herbarium, upon which Linnæus's "Hortus Cliffortianus" is based, must not be forgotten. In fact, it is not sufficiently consulted in the 'nailing down' of Linnean species by typification.

Mr. Savage is to be thanked for the arduous task he has brought to completion, and the Linnean Society praised for the publication of the Catalogue in times so difficult as those of the present.

W. B. TURRILL

RADIO REFLEXIONS FROM METEORIC IONIZATION

AT a meeting of the Physical Society held on January 31, the results of several recent researches by radar and radio methods into ionospheric ionization effects produced by meteors were described. The *E*-layer of the ionosphere, which occurs in a region around a height of 100 km., is characterized by one regular and two irregular forms of ionization. The regular ionization, the normal *E*-layer, is known to be controlled in a uniform manner by ultra-violet radiation from the sun. The problems of the origin and control of the irregular forms, which for many years have been largely a matter for speculation, were the subject of the papers presented at the meeting. In 1932, A. M. Skellett[1] in the United States had suggested that meteors were an important agency in producing irregular ionospheric ionization, and with J. P. Schafer and W. M. Goodall[2] he gave experimental evidence of certain increases in ionization which could be associated with meteors. Although the experimental data which accrued in subsequent years appeared on the whole to support Skellett's suggestions, it is only by the recent work, particularly in Great Britain, that a more comprehensive account of the complex characteristics of the irregular ionization in relation to the meteoric theory could be given.

The irregular ionization can be classified into two types, which are distinguished most clearly by the radio-frequency at which echoes may be obtained and by their duration. The abnormal or sporadic *E*-layer occurs spasmodically for minutes or hours with a critical frequency greater than, but of the same order as, that prevailing in the normal *E*-layer. On the other hand, ionization bursts are characterized by the transient radio echoes which rarely persist for many seconds, the majority lasting only a fraction of a second; and with high-power transmitters, these echoes may be observed at frequencies greatly exceeding the critical frequency of the other *E*-layers, although the number of echoes diminishes as the frequency is increased.

Sir Edward Appleton gave the opening paper at the Physical Society's January meeting, describing recent investigations carried out with R. Naismith for the purpose of comparing the incidence of the bursts of ionization with the abnormal *E*-layer ionization and of determining their relation both to the incidence of meteors and to the normal *E*-layer. The observation of the ionization bursts was made at 27 Mc./s. with a high-power equipment having a wide aerial beam with its axis vertical. An analysis of the diurnal variation of the rate of occurrence of the radio echoes showed that the form of the night-time curve was almost constant, but the day-time portion was found to alter with the season of the year. A characteristic minimum was found to occur at 1800 hr. local time throughout the year, and both the rate of occurrence and duration increased as the night progressed. In the winter, the number of bursts reached a maximum at about 0500 hr. In summer, however, the increase was found to continue until the maximum rate was reached just before or at local noon. The seasonal variation in hourly rate at noon showed a maximum burst-activity in summer; but the relation is not symmetrical, the rates being greater in the latter half of the year than in the first. These facts may be explained on the hypothesis that the ionization bursts are caused by meteors, while a marked degree of solar control is exerted over the responsiveness of the upper atmosphere. Thus, the hourly rate of sporadic meteors is known to be greater after midnight than before, and greater in the second half of the year than the first. On the other hand, the sun causes the normal *E*-layer ionization to reach a maximum near noon, the ionization being greatest in summer. A combination of these two factors would account for the observed diurnal and seasonal variations in mean rate of occurrence.

The controlling influence of the normal *E*-layer is exhibited in a parallel way in the case of the abnormal *E*-layer, which, for example, during the day shows diurnal and seasonal variations of height similar to those of the maximum normal *E*-layer ionization. Further, it is known that the abnormal *E*-layer has shown increases at the time of large meteor showers. The Giacobinid shower of October 10, 1946, afforded a particularly striking example. The remarkable increase in the number of ionization bursts at this time has been reported previously[3].

There is thus a general parallelism between the two phenomena of the bursts and the abnormal *E*-layer; and it is suggested therefore that, at least in temperate latitudes, meteors are the agency primarily responsible for both these forms of irregular ionization, although the ionizability of the medium exerts a very marked effect. This controlling effect is revealed in the day-time influence of the normal *E*-layer. The ionization bursts are pictured as being associated with individual meteor trails. That there are many more echoes than visible meteors is understandable, since the greater proportion of meteors may be expected to be too small to produce visible trails.

Sir Edward Appleton also referred to the observations he made with Naismith and the B.B.C. of the meteoric Doppler whistles heard in radio sets tuned to the unmodulated carrier of short-wave radio stations, which were first reported by the Indian workers, Chamanlal and Venkataraman[4]. He suggested that the changing pitch of the whistles could be accounted for by the changes in relative velocity with respect to the observer without assuming any retardation of the meteor. The resulting beat-frequency is:

$$f = \frac{2V}{\lambda}\left(1 - \frac{R_0^2}{R^2}\right),$$

where V is the velocity of the meteor, λ the wave-length, R the range and R_0 the perpendicular distance to the track.

J. S. Hey then gave an account of the researches he had carried out since 1944 with G. S. Stewart at the Operational Research Group, Ministry of Supply, at frequencies around 60 Mc./s. Such high frequencies limit observations to the more intense ionospheric bursts, and it was found that the transient echoes could then be more specifically related to meteors, with far less evidence of any controlling influence exerted by normal *E*-layer ionization. Thus peaks in the rate of occurrence were found to correspond to well-known meteor showers[5]. The height distribution was determined by means of an aerial beam with its axis vertical, due allowance being made for the effect of beam-width. The mean height of maximum occurrence was found to be about 95 km., and 90 per cent of all echoes occurred between

87 km. and 108 km. This height agrees well with the visually observed heights of meteors and their trains.

Observations made with radio beams having their axes inclined at elevations around 45° revealed the important influence of the direction of observation on the apparent rate of occurrence. In an experiment carried out with the help of A.A. Command during June and July 1945, stations at Walmer (Kent), Aldeburgh (Suffolk) and Richmond (Surrey), respectively, were set so that their aerial beams made broad intersections at heights around 100 km. Simultaneous observation of echoes from the three stations was a rarity, thus indicating marked aspect sensitivity in the echoing sources. This was further confirmed by the diurnal variations in rate of occurrence, which were markedly different for the three stations. The aspect sensitivity was shown to be readily explained when the transient echoes are interpreted as the broadside reflexions from meteor trails, which may be expected to show aspect variations in reflexion like those for long cylinders, as was first suggested by J. A. Pierce[6]. Thus, as the elevation and bearing of the active radiants change with the earth's daily rotation, corresponding changes occur in the optimum direction for obtaining radio reflexions. In fact, by finding the optimum directions experimentally, it has been found possible in certain instances to derive the positions of the radiants of the most active meteor streams.

Finally, during the Giacobinid meteor shower of October 10, 1946, not only were records obtained of the broadside reflexions from meteor trains (which show relatively only small range-movements due to drifts and turbulence); but also, by improved photographic techniques, the reflexions from the ionization in the immediate vicinity of the approaching meteors were recorded in certain instances. These observations and the derivations of meteor velocities were described in detail at a meeting of the Royal Astronomical Society on December 13, 1946[7,8]. During part of a shower, a watch for echoes at a frequency of 212 Mc./s. was also maintained, and the number of echoes was about one tenth of the number on a 64 Mc./s. equipment of similar power and beam width.

Dr. E. Eastwood described the investigations of ionospheric bursts of ionization which he has conducted in association with K. A. Mercer at a number of R.A.F. radar stations during 1945–46. The aerial systems gave fixed beams covering low angles of elevations over almost all bearings. Systematic observations, made over nineteen months at the Bawdsey station on a frequency of about 23 Mc./s., showed that the rate of occurrence of bursts follows a diurnal cycle with peaks at approximately 0400 hr. and 1200 hr. G.M.T. and a pronounced minimum in the afternoon. The precise form of the diurnal cycle, however, proved to be dependent on the season. The relative amplitude of the two peaks varied seasonally, but the afternoon minimum was found to be a feature of all the daily curves. The change in daily volume of activity showed an annual cycle with a maximum in the autumn and a minimum in the spring. These experimental results, as in the case of those obtained by Sir Edward Appleton and R. Naismith, were therefore in accord with the theory that attributes the bursts to ionization by sporadic meteors in an atmospheric medium subject to a marked degree of solar control.

The height of the bursts was determined from the minima in the histograms of range-distribution. These minima could be related to the minima of the aerial beam pattern which occur at several elevations as a consequence of the interference between the direct wave and that reflected from the ground. It was concluded that most ionization bursts are produced within a thin layer located at a height of approximately 85 km.

The magnitudes of the echoes were studied by using a single dipole aerial system. The derivation of the distribution function for the magnitudes showed that, for a given frequency, the number of bursts per unit area per unit time having equivalent echoing areas between A and $A + \delta A$ is proportional to $\delta A/\sqrt{A^3}$. The results of observations with equipments operating in the frequency bands 20/30 and 40/50 Mc./s. indicated that the number of bursts was also inversely proportional to the square of the frequency.

An examination of the burst-activity for local variations was made by comparing the results at different stations in England and Scotland. Although at any given time random fluctuations were found from place to place, the average activity was constant over wide areas. Further, the results obtained during the partial solar eclipse of July 1945 did not reveal any influence on the phenomenon of burst-activity.

Dr. A. C. B. Lovell described the investigations at a frequency of 73 Mc./s. which he had carried out with C. J. Banwell and J. A. Clegg in continuation of the observations of the Perseids and Giacobinids described before the Royal Astronomical Society on December 13, 1946[8]. By using the narrow-beam aerial system maintained at right angles to the direction of the radiant, the main characteristics of the 1946 Leonids, Orionids, Taurids, Geminids and 1947 Quadrantids were measured. The most important results were as follows:

(1) In the two richest showers (Geminids and Quadrantids), a striking correlation of hourly rate with radiant altitude was observed. The rate remained low (5–10 per hour) until the radiation attained an altitude of about 40°, when it increased suddenly to about 45 per hour for the Geminids and to about 60 per hour for the Quadrantids. The reverse effect was observed when the radiant was setting.

(2) Although the velocities of these meteor showers are known from visual observations to vary over a wide range, the distribution of durations of the echoes from all these five showers was identical. 60 per cent of all echoes in the showers lasted for less than 0·25 sec. Only 1 per cent had durations in excess of 10 sec. This result is important in the development of the theory of the decay of the meteor ionization, since it implies that the height at which the ionization is formed is not the principal factor determining the duration of the echo.

(3) The distribution in intensity of ionization for the Geminids and Quadrantids was calculated using formulæ given previously[8]. In each case the distribution was the same as that for the 1946 Giacobinids, namely, that the number of occurrences of ionization of a given intensity was inversely proportional to the intensity. In conjunction with Herlofson's theory of meteor ionization, this shows that the number of meteors of a given size is inversely proportional to the size of the meteors. This result agrees with the visual estimates that there is the same total mass of meteoric material in each magnitude.

The work of Chamanlal and Venkataraman[4] was further described by G. R. M. Garratt who, during a recent visit to New Delhi, was given an opportunity of listening to the meteoric whistles, which were first reported by the Indian workers when listening to the short-wave transmitters of All India Radio. The whistles normally lasted about 2–3 sec., fell rapidly in pitch to zero or sometimes died away before reaching zero, and only in rare cases did the whistle reappear as an ascending note after passing through zero. Chamanlal and Venkataraman considered that these characteristics could be explained on the assumption that they were due to interference between the directly received ground-wave from the transmitter and the reflected waves which have undergone a Doppler change of frequency owing to the movement of the reflecting surface. The velocities deduced were similar to those of meteors, and the suggestion that the reflexions were associated with meteors was confirmed by direct correlation between the occurrence of a whistle and the arrival of a visible meteor. Mr. Garratt outlined the conditions for satisfactory reception of the meteoric whistles; namely, a high-power transmitter radiating an unmodulated signal at a frequency of the order of 5–15 Mc./s., and a highly sensitive receiver located within the skip distance in a position such that a very weak ground-wave is received from the transmitter. The whistle effects can be heard on almost any night of the year, the greatest number being observed about 4 a.m.

Finally, the recent investigations in the United States by J. A. Pierce[9] were outlined by K. R. Eldridge. During the Giacobinid shower of October 10, 1946, about 3,500 Doppler whistles were recorded. Pierce considered that the Doppler effect is produced by an 'ionic bow-wave', the pitch being a function of both the velocity of the meteor and the rate of diffusion of the electrons. The pitch is presumed to fall from the first, because the growth of the cloud of ions is most rapid at its initial height, and goes to zero when recombination prevents further expansion of the boundary.

Correlations between the whistles and visually observed meteors were obtained when weather conditions permitted. In the case of two whistles, which were so loud that the visual watchers out-of-doors 40 ft. away could hear them, it was noted that the whistle was heard within the first quarter of the meteor's course, and the tone fell in pitch throughout the period of the meteor's visibility.

Pierce concluded from the average number of whistles observed that his limit of sensitivity corresponded to a third-magnitude meteor. He calculated that the average rate of flow of energy in the four hours during which the Giacobinid shower was observed corresponded to a figure of 3 watts per sq. km. By assuming that the energy was expended in a layer 30 km. thick, and that 15 electron volts are required per ion, it was calculated that the ion density would be of the same order as the maximum density of ionization in the normal E-layer at the sub-solar point. J. S. HEY

METEORS, COMETS AND METEORIC IONIZATION

On March 19 and 20 a conference on meteors, comets and meteoric ionization was held in the University of Manchester Physical Laboratories under the auspices of the Physical Society. The chairman, Prof. P. M. S. Blackett, in opening the conference, remarked that this was probably the first conference of its kind to be held. A widespread interest in meteors and comets is arising because of the new radio methods of detecting the ionization due to meteors in the atmosphere. Results of importance to astronomers and physicists are now being obtained; and it was hoped that this joint gathering would be of benefit to both.

Meteors

In the first lecture, J. P. M. Prentice, director of the Meteor Section of the British Astronomical Association, described the general background of our knowledge of meteors. The following is a brief abstract of his remarks.

(*A*) *Numbers.* The major streams exert a dominant influence on the curve of annual variation, and the rate of occurrence of a given stream is a function of the radiant altitude. The general level of meteor activity after eliminating the major streams is rather low, about 4–10 an hour, and shows daily and annual variations due mainly to the concentration of radiants around the apex of the earth's path. A particular observer sees only a small fraction of the fainter meteors appearing in his zone of vision, so that although the observed numbers fall off after magnitude 4·5, the real numbers continue to increase by a factor 2·3 per magnitude. Beyond the limits of naked-eye visibility, the number of telescopic meteors increases by the same factor at least down to magnitude 10 and probably far beyond.

(*B*) *Radiants.* The divergence of meteors from radiant points is an effect of perspective, showing that the motions of those meteors are parallel and that they form members of one stream. These radiants are apparent radiants, due to the combined orbital velocities of the meteors and the earth. Some twelve major streams are known, of which eight appear annually; in addition, there are many minor streams of varying degrees of tenuousness, and some meteors pursuing individual paths in space properly called 'sporadic'. A very few streams are known from the similarity of their orbital elements to be associated with comets, although the proof is only complete for the three instances (possibly four) in which the periods have been determined. The majority of radiants are not points but large areas of radiation some 10°–15° in diameter.

(*C*) *Paths in the Atmosphere.* The meteor zone lies generally at an altitude between 125 km. and 70 km., though exact limits cannot be assigned. The height of appearance and disappearance is determined primarily by the entrance velocity, although the beginning height is also correlated with the zenithal magnitude. This difference in height is generally a function of zenithal magnitude only, being sensibly independent of velocity and of radiant altitude except for very low radiant altitudes. The heights are determined by simultaneous observations, which also yield the path-length P and the duration of flight t, and hence the observed velocity P/t. There is some observational evidence of a general deceleration due to atmospheric resistance, but this is not universally accepted.

(*D*) *Velocities.* These may be determined by either direct or indirect methods. The principal direct methods are (*a*) by simultaneous observations as above, or (*b*) by observing periodic recurrences of a stream. The indirect methods are (*c*) from the daily and annual variation in numbers (the method of von Niessl[1] and Hoffmeister[2]), and (*d*) from the observed heights, which give more reliable values than P/t. The only really accurate method is the observation of periodic recurrences, as an error of only 0·5 km./sec. usually makes a considerable difference to the orbit; but these recurrences are very difficult to establish. The method of von Niessl and Hoffmeister has led to the belief in hyperbolic velocities as a normal occurrence; but the method is an indirect one and at variance with direct observations and is not considered valid.

Comets and their Relationship with Meteors

The second lecture was given by Dr. J. G. Porter, the director of the Computing Section of the British Astronomical Association, who spoke on the relationship between comets and meteors. Both classes of body are now known to be members of the solar system, travelling around the sun in elliptical orbits; those few cases of hyperbolic orbits which can be substantiated are known to be caused by perturbations of elliptical orbits by the major planets. The head of a comet must possess mass, since it obeys the law of gravitation, but that mass must be very small. All the evidence supports the view that the head consists of solid particles composed of meteoric material. But whereas in a meteor stream the individual particles must be many miles apart (10–20 miles even in the extreme case of the great Leonid shower of 1835), in the head of a comet the distances may be measured in yards. Some force other than gravity is apparently needed, however, to account for the remarkable coherence of the head, which in many comets has undergone enormous disturbances without disruption.

After discussing the effect of planetary perturbations on a meteor stream, Dr. Porter expressed the view that there is no sound evidence that meteor streams are the remains of disrupted comets. The one case which is always quoted—that of Biela's comet—carries very little weight when examined closely. The comet divided into two parts in 1846—apparently without cause—was seen once more in 1852, and then vanished. But in 1872, when the earth crossed the orbit of the comet, a magnificent display of meteors was seen. The meteors could not have been the remains of the head of the comet, for the place where the earth crossed the orbit was far from the computed position of the comet itself. Perturbations by the major planets certainly could not have caused sufficient disturbance in the intervening twenty years to have spread the meteoric matter out over the orbit. All that can be said is that the meteor shower travelled in the same orbit as the comet, and this applies equally to other well-known showers. The Bielids had given good showers before, while the great showers of Lyrids, Leonids and Perseids can all be traced back in history long before the associated comets were discovered.

Actually there are very few accordances between meteor showers and comets—only six of the better-known showers give satisfactory agreement with their associated comets. Yet there are many minor showers for which the parent comet is unknown, and there are many comets which come close enough to the earth to give a shower, but do not do so.

We are forced to conclude that there is no *direct* evidence of the disruption of comets to form meteor streams. All that can justly be claimed is that there are some cases known in which a meteor stream follows the same orbit as that of a comet, and it seems plausible to suggest that comets and meteors have a common origin.

Ionization Due to Meteors in the Atmosphere

In the first lecture of the afternoon session, Dr. A. C. B. Lovell gave a survey of the known effects of meteoric ionization in the earth's atmosphere. Evidence that the ionization in the *E*-region of the ionosphere does not decrease in a regular manner during the night but is subject to abnormal increases was obtained in the early days of the ionosphere work by Heising[3] in the United States, and by Eckersley[4], Appleton[5] and their co-workers in Great Britain. Subsequent work tended to divide the abnormalities into two classes: (*a*) long-duration increases of ionization lasting for minutes or hours, found on frequencies just above the normal critical frequencies (abnormal or sporadic *E*); (*b*) short-duration bursts of ionization lasting for a fraction of a second or a few seconds, which could also be observed on very much higher frequencies. Both effects occurred by day and night throughout the year. As a result of a great deal of work since 1930 by Appleton, Naismith, Ratcliffe and others in Great Britain, and by workers in India and the United States[6], it now seems certain that the long-duration abnormal *E* is associated with two separate effects: (1) the incidence of solar corpuscles, associated with magnetic disturbances and hence most pronounced in polar regions; (2) the ionization due to meteors, which constitute the main abnormal effect in temperate latitudes. With regard to (*b*), Skellett[7] and Schafer and Goodall[8] showed, by a combined visual and radio watch during the Leonid shower of 1932, that the short-duration abnormalities were caused by the entry of meteors into the atmosphere.

After describing subsequent work on the short-duration ionization bursts by Eckersley[9], Appleton and Naismith[10], Dr. Lovell gave a short account of contemporary studies of the effect using frequencies in the 60–70 Mc./s. region, which are high enough to be clear of the confusing effects of the longer duration abnormal *E*. Hey and Stewart have investigated many of the properties of the radio echoes from meteors and have succeeded in determining radiants[11] and velocities[12]. In the determination of velocities, these workers were able to photograph a faint fast-moving echo prior to the formation of the main radio echo. The analysis of twenty-two such photographs during the Giacobinid shower of October 1946 gave a velocity of 22·9 km./sec., in close agreement with the value of 23·7 km./sec. expected from theoretical considerations. The lecture concluded with a short account of the work of the Manchester group, who have explored the major streams by using a narrow beam aerial which can be directed to any point in space. For the meteors in the Giacobinid, Geminid (1946) and Quadrantid (1947) showers the intensity of ionization giving rise to the radio echoes has been calculated[13]. The distribution in number of these intensities obeys an inverse power law with an exponent close to unity. On Herlofson's theory of meteor ionization (see later) this also gives the distribution of meteor masses in the stream—

a result in agreement with visual observations that the mass of meteoric material in each magnitude is the same. These measurements also show that a meteor which is just visible to the naked eye produces about 10^{10} electrons/cm. path—a result which is again in good agreement with Herlofson's theory[14]. Dr. Lovell ended by showing a ciné film of the radio echoes during the maximum of the Giacobinid shower in October 1946, when the echo-rate reached an enormous peak of 160 per minute for a very short time, compared with the normal no-shower rate of one or two per hour on this apparatus.

Theory of Meteor Ionization

N. Herlofson then gave an account of the theoretical aspects of meteor ionization in the atmosphere. Observations by the Manchester group, referred to above, show that the echoes recorded by their apparatus, at 4 metres wave-length, are due to scattering from columns of electrons with densities of 10^{9}–10^{11} electrons per cm. length. These values are in reasonable agreement with quantum-mechanical estimates of the ionization produced by meteors visible to the naked eye, or somewhat fainter. The majority of the echoes disappear after less than one second, a great number lasting only a few tenths of a second; but durations of some seconds are not uncommon, and durations up to 100 seconds have been recorded.

So far, all attempts to find a correlation between duration and height in the atmosphere have been unsuccessful. Another remarkable feature is the occurrence of strong and rapid fluctuations in the intensity of a number of the longer echoes.

A study of the scattering from electrons with a radial Gaussian density-distribution suggests that diffusion is important for the rate of decay of the echoes. Electrostatic forces prevent a separation of the electrons and the positive ions, and the effective diffusion coefficient for the ionized matter will be a weighted mean of the diffusion coefficients for electrons and for positive ions. In a direction normal to the magnetic field of the earth, the diffusion of the electrons will be hampered by the electromagnetic force, while the electromagnetic force does not affect the diffusion in a direction parallel to the magnetic field lines. The resulting elliptical distribution of electrons around the track of the meteor will present its broad side to the radio station in the regions of the sky 90° away from the magnetic zenith, and its sharp edge if it appears close to the magnetic zenith. Therefore, the duration of the echoes will depend both on height in the atmosphere and on the angular distance from the magnetic zenith to the reflexion point on the meteor trail. In Northern Europe, a belt near the northern horizon will be favourable for echoes of long duration, and some observational evidence already exists in support of this conclusion[15].

The wind systems revealed by visual observations of the rare luminous trails, lasting for half an hour or more[16], show that meteor trails can be expected to deviate from a straight line by several metres even after one second. Such deformations can produce a sudden increase of the echo if part of the trail is brought to coincide with one of the spherical wave surfaces. Further deformations may lead to several reflexion points along the trail, and the observed oscillations in echo intensity can be explained by the varying phase difference in the radiation scattered from the various reflexion points.

Since only deformations *along* the radius from the radio stations are effective, and winds are mainly horizontal, oscillations will preferably occur in echoes observed at low elevations. Combining this conclusion with the expectation of long-duration echoes near the northern horizon, it is possible to understand that long durations are frequently accompanied by fluctuations in intensity at stations in the British Isles.

Observations in equatorial latitudes, where the magnetic field lines are nearly horizontal, can provide a decisive test for these suggestions. We should expect to find echoes of long duration decaying *steadily* near zenith, echoes of long duration showing fluctuations near the eastern and western horizon, and echoes of shorter duration near the northern and southern horizon.

On March 20, the conference was continued informally at the Jodrell Bank Experimental Station of the University of Manchester, where the apparatus in use by the Manchester group of workers was inspected.]

NUTRITION AND SYMBIOSIS*

By Dr. E. C. OWEN
Hannah Dairy Research Institute, Kirkhill, Ayr

NUTRITION may be taken to include all those processes by which chemical substances essential to the life of a given species, be it plant or animal, become available for anabolism. Thus in plants, nutrition includes photosynthesis and root absorption, as well as the processes of digestion which occur in animals and insectivorous plants. The term 'symbiosis' in its original and widest sense signifies any phenomenon, from a balanced parasitism to complete mutualism, in which each partner gains nutritional benefit from the presence of the other. Such diverse phenomena as the harbouring of specific fauna and flora in the gut of insects and vertebrates and the occurrence of algæ in the cells of *Hydra viridis* are, in the widest sense of the term, symbiotic.

Symbiosis is a phenomenon of very general occurrence in both the plant and the animal realms.

---

* Paper read before the Society for Experimental Biology on September 25, 1946.

Examples are known in almost all classes of plants. The consortium of alga and fungus exhibited by the lichen is the classical example. Mycorrhiza is found not only in conifers but also in deciduous trees and other flowering plants, and in the ferns. A parallel phenomenon is encountered in the bryophytes[1]. Bacteria causing root nodulation occur not only in legumes but also in other widely different plants, for example, *Alnus* and *Cycas*. In the animal kingdom symbiosis is a very common occurrence, particularly in the wood-eating insects such as the termites, and in the larvæ of wood-eating roaches, of wood-wasps and of other insects which subsist on a diet rich in cellulose[2].

Though many examples of symbiosis have been known for more than a hundred years, evidence for mutualism is still being examined. Even when, as with the mycorrhizas of forest trees, investigations are still in a highly debatable stage, the evidence for mutualism is increasing, for very often a particular species of fungus fructifies, in Nature, only on litter beneath trees on which it forms mycorrhizas, while conversely the healthiest of forest trees have mycorrhizas.

It may be much easier to prove the dependence of one partner than that of the other. Thus in the germination of orchid seeds it has been shown that the seeds of some species need to be attacked by their specific fungal associate at germination, while others need the fungus for continued development. The simple embryo of the orchid, though small, contains a food reserve in the form of oil, and it has been suggested that the fungus may in some way render the oil more readily available to the developing embryo. The dependence of the orchid *Goodyera repens* on its fungus is of this type[3]. The dependence, however, goes beyond assistance at germination, for, on sugar, growth is limited, and to complete its development *Goodyera repens* needs to be penetrated by its fungus even if sugar has produced its early development. In pine trees the dependence seems to be of a different kind. Successful germination occurs in the absence of the fungus, though it is claimed that establishment of mycorrhiza is necessary for production of thrifty trees[4].

In the humus-rich soils of forests, sporophores of mycorrhiza-forming fungi are common[1]. There is an analogy here between such humus-inhabiting fungi living in what is really the excreta of trees, and the bacteria found in the alimentary tracts of animals of a wide variety of species.

Symbiosis may be raised to the status of mutualism if it is proved that the apparently parasitized partner actually benefits from the parasitism. The root nodulation so common in legumes is an example of mutualism[5,6]. In exchange for energy-producing nutrients, the *Rhizobium* provides chemically combined nitrogen to the host, so that the overall effect is that the legume can grow in a culture solution devoid of combined nitrogen[5,6]. Dependence in this instance, however, has not become obligatory, for both the *Rhizobium* and its host can have independent existences if their respective environments permit, the *Rhizobium* saprophytically and the legume holophytically.

The fixation of nitrogen by *Rhizobium*, *Azotobacter* and *Clostridium pasteurianum* has led to investigations of the possibility of the fixation of nitrogen in other symbiotic associations. Thus Cleveland attributed nitrogen fixation to the protozoans (*Hypermastigota*) inhabiting the hind-gut of certain species of termites. This fixation has not so far been confirmed. Cleveland[7] based his conclusions on observations of the effects of diet and defaunation on the longevity of the termites. Since starving insects may remain active for very long periods, such methods of observation need careful control.

The claim by Peklo[8] to have demonstrated fixation of atmospheric nitrogen by symbionts in the mycetomes of aphids rests on stronger grounds, since he claims to have identified the symbionts as species of *Azotobacter* and refers to the work of others who investigated the rate of acquisition of nitrogen by aphids. Even in these cases, there is the possible explanation that nitrogenous metabolism of insects may be much more efficient than that of mammals. In any attempts to repeat Cleveland's experiments the use of isotopic nitrogen would be very advantageous. The fixation of nitrogen can be proved only by demonstrating a real increase of the nitrogen content of an organism or of the medium in which it is growing. An increase in the percentage of nitrogen, such as occurs in the decay of plant materials due to bacteria or fungi, usually means merely that dry matter has been lost as carbon dioxide.

A symbiotic relation between bacteria and animals is the basis of the commonest method by which various land animals digest cellulose, for the secretion of cellulase, as happens in the snail and in certain wood-eating insects, is uncommon. In the cæcum and in the colon of the mammal, microscopic examination shows that bacteria are mainly responsible for the power of mammals to digest cellulose-containing materials. Pre-eminent, however, in this regard are the ruminants, both wild and domesticated. In them the paunch, an enlargement of the œsophagus, forms a fermentation vat teeming with bacteria and highly specific protozoans. Because of their fascinating appearance under the microscope, the protozoal inhabitants of the rumen have been the subject of more speculations as to their mutualistic functions than have the bacteria. All experimental work, however, has so far proved the over-riding importance of the bacterial symbionts in ruminant digestion. It is more than fifty years since German biologists[9] suggested that the rumen bacteria conferred a benefit on their hosts by elaborating digestible materials in their own bodies: only in the last few years, however, have these benefits been in any way adequately or rigorously defined. We now know that the rumen bacteria synthesize protein from ammonium nitrogen in the rumen and that they store carbohydrate as bacterial polysaccharide[10]. We also know from experiments in which such bacterial bodies have been fed to rats that their protein is available for anabolism after digestion by the host. Similar biochemical and microbiological changes occur in the cæcum of the horse, the rat, the rabbit, the guinea pig and the pig, in the cæcum of the ruminant itself, and in the colon of mammals generally, and serve to explain the very variable powers of digesting cellulose found in different mammalian species. In all species so far examined, it appears that such digestion of cellulose as occurs is due to bacteria morphologically describable as cocci but not so far further characterized. There have in the past been claims to show that in the paunch of the ruminant the protozoans also digest cellulose, but in this case mere microscopic examination is of little value because it is impossible to tell whether such apparent cellulolysis is due really to protozoal secretions or to the activities of bacteria adhering to the surface of the plant fragments ingested by the protozoans. Hungate[11], however, claims to have prepared a cellulase from rumen protozoans fed in isolated culture on non-cytoclastic bacteria.

An important effect of the bacteria in the rumen is their production, from sugar, starch, cellulose and other carbohydrates, of quantities of lower fatty acids. Phillipson and his colleagues at Cambridge have investigated the production of lower fatty acids in the rumen of the sheep, and have discovered a great preponderance of acetic acid[12,13]. McNaught and Smith[10] have shown that liquor, carrying its mixed bacterial flora, abstracted from the rumen of the steer, produces acetic acid from carbohydrates when incubated *in vitro*. Moreover, Phillipson and his colleagues have shown that acetic and other lower fatty acids are directly absorbed through the walls of the sheep's rumen, whence they pass via the portal circulation to the liver. Thus, much of the carbohydrate of its diet is made available to the ruminant by mutualistic symbiosis. The ruminant provides the bacteria with their preferred substrate, and in return has part of its carbohydrate digested for it.

Investigations of the causes of the deficiency diseases beriberi and pellagra, which occur in the more poverty-stricken parts of the world, led eventually to the unravelling of the complex collection of organic micronutrients necessary for animal life which we now call the vitamin B complex. The members of this complex now number more than ten, and the identification of further members is proceeding. The identification of these vitamins of the B-complex and the demonstration of their occurrence in practically all forms of life, whether green plants, fungi, protozoans or mammals, has greatly increased the number of instances of symbiosis which must now be regarded as true cases of mutualism.

There is no mystery as to the origin of the vitamins n the body or in the milk of a cow, sheep or other grass-eating or browsing animal. Green leaves seem to be portmanteaux packed with all essential animal nutrients[14,15]. Cows, however, often exist in winter on diets in which sufficient of the members of the vitamin B complex cannot be demonstrated. Such animals secrete in their milk and urine much more of certain members of the B-complex, for example, riboflavin and nicotinic acid, than can be found in their diet. Factors of the B-complex are synthesized by the symbionts inhabiting the rumen, probably by the bacterial symbionts, though this last point is still in need of rigorous proof[16].

Other animals have been found to be independent of an external source of the B-complex. Indeed, what is now known to be a mutualistic association of the rat and its intestinal bacteria was once the cause of much trouble in early attempts to assay members of the B-complex by using rat-growth as an index. Certain rats on experimental diets free from the vitamin under test were found to suffer no disability, whereas others succumbed on the same diet. Fridericia[17] in Denmark showed that the ability to withstand such deficiencies is not necessarily due to coprophagy, that is, the eating of their own droppings, but is due to a power developed by some rats of synthesizing the vitamins of the B-complex. Later investigations have shown that it is the bacteria inhabiting the gut which synthesize the B vitamins for the refected rat, because such refection is inhibited by dextrinizing the raw starch in the diet or by adding filter paper to the diet. It is also either inhibited or diminished by surgical removal of the rat's cæcum or by the administration of non-absorbable sulphonamides such as succinyl sulphathiazole[18-20]. In this last type of experiment, Light and others[21] have shown that growth is resumed when rats ingesting sulphonamide are allowed to eat fæces of rats on the same diet but without the sulphonamide. In the rat, and perhaps in the ruminant, it has been shown that the fat-soluble vitamin K can also be synthesized by symbiotic bacteria.

There is evidence that even in man himself[22], in certain circumstances which still need accurate definition, the bacteria in the large bowel can synthesize aneurin and niacin[23]. In the rat and the mouse, evidence has been produced which suggests that some members of the B-complex, for example, inositol, are not needed directly by the animal but as micronutrients for its symbiotic bacteria[24]. The power of man's own symbionts to synthesize members of the B-complex may explain why the incidence of such diseases as beriberi and pellagra varies markedly in areas where they are endemic.

Circumstantial evidence as to the obligate nature of the symbiosis of insects and bacteria or actinomycetes is provided by studies of the manner in which these symbionts reach the eggs of the host, cases being known where the embryo is infected at the time of laying and before the egg-membrane is formed. Mansour and Mansour-Bek[25] believe that such evidence does not justify the attributing of mutualism to such symbiosis. In many cases, however, mutualism has received rigorous proof. Thus Rosenkrantz[26] in 1939 demonstrated the presence of symbiotic bacteria in stink bugs (Hemiptera, Heteroptera), and showed the presence of organs in the body, the function of which is to ensure that eggs become infected as they are laid. In twenty-three families of the same group (Heteroptera), Schneider[27] showed that larvæ hatching from such eggs developed normally, whereas larvæ from sterilized eggs survived only six to nine days. Brecher and Wigglesworth[28] have shown that when deprived of its actinomycetes *Rhodnius prolixus* rarely reaches the imaginal stage, and that any imagos which are produced are sterile unless they are allowed to become re-infected with the actinomycete. Growth is resumed when larvæ are allowed to become re-infected.

In the hemipterous insect *Cicadella viridis*, Mahdihassan[29] has demonstrated two bacterial symbionts, one producing a green pigment, sarcinene, and the other producing β-carotene. Mahdihassan states that β-carotene is needed by the insect, which changes it to vitamin A. This observation, if confirmed, is a case of mutualism affecting a fat-soluble vitamin other than vitamin K.

Perhaps the most interesting case of symbiosis affecting synthesis of the B-complex is in the insects investigated by Blewett and Fraenkel[30], who were comparing the susceptibilities of various grades of flour to damage by insects. Fraenkel and Blewett raised insects from disinfected eggs. The insects investigated were two beetles which commonly infest stored flour and grain, *Lasioderma serricorne* and *Sitodrepa panicea*. They had noted in earlier researches that *L. serricorne* and *S. panicea* did not appear to require certain members of the B-complex in their diets because they could develop normally in flour of 75 per cent extraction (N.S.R.), while two other beetles also infesting grain and flour, *Tribolium confusum* and *Ptinus tectus*, could not grow normally on National Straight Run flour unless yeast was added. *Tribolium* and *Ptinus* developed normally on wholemeal flour. In many insects symbiotic bacteria or fungi are enclosed in special organs called 'mycetomes'. Microscopic examination of Fraenkel and Blewett's beetles showed that the former two species which could do without the B-vitamins possessed mycetomes containing symbiotic yeast-like organisms while the latter two species did not. Fraenkel and Blewett, therefore, supposed that *Lasioderma* and *Sitodrepa* were dependent on their symbionts for their supplies of essential water-soluble vitamins. They proved the truth of their hypothesis by showing that in the absence of their symbionts, *Lasioderma* and *Sitodrepa* lose their power of living on a diet lacking certain members of the B-complex. They also showed that, when freed from symbionts by being hatched from sterilized eggs, *Lasioderma* and *Sitodrepa* behaved in much the same way as did *Tribolium* and *Ptinus* when subjected to diets deficient in certain members of the B-complex.

To summarize these observations on symbiosis and nutrition, it may be said that examples of symbiosis which have long been known have, by morphological and biochemical researches, been raised in some cases to examples of what we may call mutualism.

The fixation of nitrogen by *Rhizobium radicicola* living in the roots of legumes proves this symbiosis to be a case of mutualism.

While mycorrhiza is essential to the normal development of the orchid, it is not essential to the life of the fungus producing it, for the latter lives quite successfully as a saprophyte in dead pine needles, or even when grown in a simple synthetic medium with dextrose and mineral salts. In those orchids which are devoid of chlorophyll, the mycorrhizal condition is associated with a completely saprophytic habit, and the dependence of the orchid on the fungus is obvious.

The manner of establishment of mycorrhiza varies in different plant orders for, while orchid seeds are shed quite free from fungus, the grains of the rye-grass *Lolium* are regularly infected. The mechanism of infection in *Lolium* is reminiscent of the method found in certain insects in which the eggs are automatically infected before they are laid. The status of the mycorrhizas of forest trees still has to be decided. Circumstantial evidence is, however, strongly in favour of a real dependence of such trees on their mycorrhizal fungi.

In ruminants, symbiotic bacteria, yeasts and protozoans inhabit the paunch. Similar microbiological pictures are shown by the cæcum and colon of various mammals, including man. That the bacteria in all these cases benefit their hosts is not easy to prove. That the bacteria of the paunch of ruminants do, however, benefit their hosts has been shown by the following observations: (1) Rumen bacteria digest cellulose whereas the ruminant itself cannot[31,32]. (2) They generate acetic acid from carbohydrates and thus assist in their digestion. (3) They elaborate protein from ammonium nitrogen, and this protein, together with bacterial polysaccharide, becomes by autolysis and normal digestion available to the host[33,34]. The elucidation of the chemistry of the water-soluble vitamins of the B-complex has shown that many bacteria inhabiting the bodies of mammals and insects provide their hosts with an endogenous source of these vitamins. There is evidence that even in man B-vitamins are produced by bacteria in the colon. Further investigations will probably greatly extend the list of animals with such an endogenous symbiotic supply of B-vitamins.

Some of the results of recent investigations of the symbiotic relations of micro-organisms and mammals have been discussed elsewhere[35,36].

OBITUARIES

Dr. D. E. Lea

RADIOBIOLOGY has suffered a serious loss by the death of Douglas Lea as the result of an accident at the early age of thirty-seven. In his short life he had already become one of the leading authorities in the world on the fundamental aspects of the mechanism of the biological actions of ionizing radiations. Fortunately, he had summarized his work and ideas in an excellent book entitled "Actions of Radiations on Living Cells" (Cambridge University Press, 1946). This book is his memorial and is likely to influence radiobiology and radiotherapeutics for many years to come.

Douglas Edward Lea was born in Liverpool on February 8, 1910. From Liverpool Collegiate School he went with scholarships to Trinity College, Cambridge, in 1928. He gained firsts in Part 1 of the Mathematical Tripos in 1929, and in Part 2 (Physics) of the Natural Sciences Tripos in 1931. The whole of his working life was spent in Cambridge. He started research in physics, working in the Cavendish Laboratory with Lord Rutherford and Dr. (now Sir James) Chadwick. In 1934 he made the discovery of the capture of a neutron by a proton to form a deuterium nucleus with emission of gamma radiation. For this and related work he was elected to a fellowship at Trinity in 1934. He took the degree of Ph.D. (Cambridge) in 1935. Then he turned to biophysics, and went to work at the Strangeways Laboratory, first with a grant from the British Empire Cancer Campaign and then during 1942–46 as Prophit Student of the Royal College of Surgeons. His first work in this field was a study of the mechanism of the bactericidal action of radiations, made in conjunction with his friends Drs. R. B. Haines and C. A. Coulson, and was a promising beginning, with quantitative interpretation of the results in terms of the target theory. Although twenty-one out of his thirty-one biological papers were published in collaboration, it is evident that in many of them Lea made a major contribution both to the experimental technique and the quantitative interpretation. His experimental skill, developed during his period of training at the Cavendish Laboratory, is demonstrated in his papers on a radiation dosemeter and automatic devices for controlling the output of X-ray tubes, and the X-ray equipment he built at the Strangeways Laboratory. He went to great pains to learn the necessary biological techniques, as shown, for example, in his paper on the delayed lethal action of radiations on chick embryos.

Lea's outstanding contributions to radiobiology are to be found in his papers on the target theory of gene mutation, the variation with wave-length of the biological effects of radiations, the inactivation of viruses and enzymes by radiations and the mechanism of induction of chromosome aberrations by radiations. Of great interest and importance was his work in collaboration with Dr. D. G. Catcheside on chromosome aberrations in *Tradescantia*, in which was made the remarkable theoretical prediction, with experimental verification, of the sharp maximum in efficiency of chromatid breakage by soft X-rays at a wave-length between 4 and 5 A.

During the last few years Lea was becoming increasingly interested in the mechanism of radiochemical reactions in relation to biological effects. In October 1946 he was appointed reader in radiobiology in the Department of Radiotherapeutics of the University of Cambridge, though on account of the shortage of laboratory space he continued to work at the Strangeways Laboratory. Only two days before his death he was informed that he had been successful in his application for the degree of Sc.D. of the University of Cambridge. He had many plans, and had arranged to take leave of absence during the next academic year to work at the Memorial Hospital in New York.

Lea had come to occupy an exceptional position as collaborator, adviser and friend to a great many workers in a wide range of subjects requiring the application of biophysical, statistical and mathematical techniques. We all liked him for his unending kindness, his integrity, his modesty and his patient helpfulness. He always produced the information required, without considering time or trouble. It is very difficult to estimate the extent of his influence. Although it could be said that his work was his main interest, he was also essentially a family man, and greatly devoted to his wife and two young children.

J. S. MITCHELL

K. H. Stephensen

AFTER a short illness from pneumonia Knud Hensch Stephensen, inspector of the University Zoological Museum of Copenhagen, died on March 13.

Stephensen was born on November 29, 1882, and took his degree as *candidatus magisterii* at the University of Copenhagen in 1907. Besides teaching at a grammar school, he at once embarked upon the study of crustaceans, which held his interest for the rest of his life. From 1914 he was curator of the crustacean collections of the University Zoological Museum and was thus the successor of H. J. Hansen and, before him, Henrik Kröyer; under his care, the collections were kept in excellent order and grew considerably. At the same time he was a very productive investigator, the total number of his papers being about 130; practically all of them deal with crustaceans and pycnogonids.

Stephensen's work was primarily systematic and faunistic, and he seldom attempted to draw general conclusions of a higher order; but all his papers bear witness to his deep penetration into his subject; he was a capable draughtsman, and had a thorough knowledge of the literature of the Crustacea. He dealt with almost all groups of the Malacostraca, and was one of the few systematicists left who really mastered this big group. But even he had to realize the necessity of specialization; and he chose one of the most difficult and largest groups, the amphipods. A long series of papers appeared on the North Atlantic species, benthonic as well as planktonic; big reports on the collections of the *Ingolf* and the *Thor* Expeditions were followed by papers on collections from almost every part of the world. At his death he was undoubtedly the leading authority on the systematics of amphipods. Yet one of his last papers—and an excellent one—was on the crabs of the Persian Gulf.

Stephensen led a happy life; he was enthusiastic about his work, whether sitting quietly at the microscope in the museum or collecting in the field. In 1912 he spent the summer in West Greenland studying the fauna of the fjords; during 1921–22 he took part in the *Dana* Expedition to the Sargasso Sea, West Indies and the Gulf of Panama, and in 1925 he collected in the Faroe Islands.

While his publications show him mainly as a carcinologist, Stephensen's general interests were wide; he was a keen all-round naturalist and also much interested in architecture and archæology. Many colleagues all over the world will miss his long and personal letters, written in his beautiful handwriting —colleagues who became his friends for life, if they happened to visit Copenhagen and once experienced the friendliness and hospitality of Stephensen and his wife.

Stephensen considered a sound taxonomy of fundamental importance to all branches of biology, ecology, physiology, etc., a view which has not been sufficiently appreciated by many working in these fields; so much the greater was his pleasure when, in 1946, he was made a corresponding member of the Linnean Society of London, for he took it as a token that his work on the lines of Linnæus, whom he admired very much, had not been in vain.

Every empty chair in the field of zoological systematics is difficult to fill nowadays, and Stephensen's death means a great loss to Danish zoology; but his authority will be missed beyond the borders of his own country.

ANTON FR. BRUUN

NEWS and VIEWS

Theoretical Physics at Manchester: Prof. L. Rosenfeld

DR. LEON ROSENFELD has now taken up the position, to which he was recently appointed, of professor of theoretical physics in the University of Manchester in succession to Prof. D. R. Hartree. Prof. Rosenfeld was born in 1904 in Liège, graduating there in 1926. He then spent a year in Paris at the École Normale Supérieure, during which he worked with Prof. Louis de Broglie. His first published work, on five-dimensional relativity, appeared about this time. In 1927 he went as assistant to Prof. Max Born in Göttingen, and while there worked on problems of optical activity and the Faraday effect; then to Zurich with Prof. Pauli, where he studied quantum electrodynamics. In 1931 he became a teacher in the School of Electrical Engineering at Liège. From 1930 until 1940 he worked in very close collaboration with Prof. Niels Bohr, spending a considerable part of each year in Copenhagen. In 1935 he was elected to the chair of theoretical physics at Liège, and in 1940 moved to a similar chair at Utrecht in Holland. Prof. Rosenfeld is one of the leading theoretical physicists of to-day and is distinguished not only for his great original contributions to the most difficult and deep parts of modern quantum mechanics and nuclear structure, but also for his wide knowledge and scholarship. He is now completing a book on the quantum theory of nuclear forces which should prove valuable to all theoretical workers on nuclear structure. In his new position in Manchester he will add greatly to the strength of theoretical physics in England. He will be in very close touch with the experimental researches being carried out in the laboratory of Prof. P. M. S. Blackett.

Case Institute of Technology: Dr. T. K. Glennan

DR. T. KEITH GLENNAN, now an executive of the Ansco Division of General Aniline & Film Corporation, Binghamton, New York, and war-time director of the U.S. Navy Underwater Sound Laboratory, has been appointed president of the Case Institute of Technology. Dr. Glennan will be the first business executive to head the Cleveland engineering school, which has had but three presidents since its establishment sixty-seven years ago as the Case School of Applied Science and which adopted its new name on July 1. He succeeds Dr. William E. Wickenden, who retires on September 1, after eighteen years of service.

Dr. Glennan received the Medal for Merit, the highest civilian award which the U.S. Government can bestow, for his work during 1942–45 at the U.S. Navy Underwater Sound Laboratory, which was operated by Columbia University at New London, Conn., for the Office of Scientific Research and Development, headed by Dr. Vannevar Bush. As director of this laboratory he guided the development of various submarine detection and location devices. One of these, the expendable radio sono-buoy, is described in James Phinney Baxter's Pulitzer prize volume, "Scientists Against Time", as "one of the outstanding developments of the war". This device led to the destruction of a large number of German submarines and played an important part in the Battle of the Atlantic.

Electrical Engineering in the University of Alberta: Prof. J. A. Harle

MR. J. A. HARLE, head of the Technical and Research Department of Messrs. A. Reyrolle & Co., Ltd., has been appointed professor of electrical engineering in the University of Alberta at Edmonton, Canada, and is sailing early in August to take up his appointment on September 1. He served his time with Messrs. C. A. Parsons and Co., Ltd., and studied at Armstrong (now King's) College under the late Prof. W. M. Thornton, graduating with distinction in 1919. He was appointed lecturer in electrical engineering at Armstrong College in the same year. In 1922 the late Mr. Clothier invited him to join the Technical and Research Department of Messrs. A. Reyrolle & Co., Ltd., and he took over the headship of the Department in 1937, when he succeeded Mr. B. H. Leeson. Mr. Harle served as chairman of the North-Eastern Centre of the Institution of Electrical Engineers during the session 1944–45, and he has been the Institution's area member for the Education and Training Advisory Service for returned Service members. He is particularly interested in insulation and circuit-breaking problems, both from the research and from the standardization point of view.

Genetical Society of Great Britain: Honorary Members

AT the annual general meeting of the Genetical Society of Great Britain, held at Rothamsted Experimental Station, Harpenden, on July 3, the following were elected honorary members of the Society: Prof. Herman Joseph Muller, Department of Zoology, Indiana University, Bloomington, Ind., who has played a leading part in the analysis of the genetics of *Drosophila*, and is known especially for work on the induction of mutation by X-rays, which he initiated and developed; Prof. Otto Renner, Department of Botany, University, Jena, known for his analysis of the genetics of *Oenothera*, by which he solved a problem which had exercised evolutionists for twenty-five years, and also for his outstanding work on the autonomy of plastids; Prof. Øjvind Winge, Carlsberg Laboratorium, Copenhagen, distinguished for his studies on the sex chromosomes, especially of fish and of flowering plants, by which he successfully demonstrated the evolution of the XX-, XY-chromosome mechanism, also for his distinguished researches on the genetics of wheat and of the ever-sporting stock (*Matthiola*).

International Union of Crystallography

AT an international conference of crystallographers held in London in July 1946 under the auspices of the X-ray Analysis Group of the Institute of Physics (*Nature*, 158, 260 (1946); *J. Sci. Instr.*, 24, 1 (1947)) a committee was appointed to prepare a permanent international organisation of crystallographers. This task has now been achieved, and an International Union of Crystallography has been formed and recognized by the International Council of Scientific Unions. In the countries adhering to the Union, national crystallographic committees will be set up. Among the purposes of the new Union listed in the statutes are the promotion of international co-operation and publication, and the representation of crystallography in its relations to other sciences. The first full constitutive general assembly may be delayed for a year or two, until a full-scale international gathering becomes desirable after the meeting in 1946; but the committee charged with preparing the formation of the Union has been authorized to carry on meanwhile as the executive committee. The acting general secretary is Dr. R. C. Evans, Crystallographic Laboratory, Cavendish Laboratory, Cambridge, England, to whom all correspondence should be directed.

Acta Crystallographica

The most urgent task confronting the new Union of Crystallography is the re-establishment of an international journal for publishing crystallographic research. Thanks to generous financial support from the United Nations Educational, Cultural and Scientific Organisation and from many research associations and industrial organisations in Britain, preparations are now well advanced for the launching in January 1948 of *Acta Crystallographica*, a journal to appear in six issues a year under the editorship of Prof. P. P. Ewald (Queen's University, Belfast, Northern Ireland), with Dr. R. C. Evans (Crystallographic Laboratory, Cavendish Laboratory, Cambridge, England), Prof. I. Fankuchen (Brooklyn Polytechnic Institute, 99 Livingston Street, Brooklyn 2, N.Y., U.S.A.), Prof. A. V. Shubnikov (c/o Academy of Sciences, Moscow, U.S.S.R.) and Prof. J. Wyart (Laboratoire de Minéralogie, La Sorbonne, 1 rue Victor-Cousin, Paris V, France) as regional co-editors. The Cambridge University Press will be the publishers and general distributors; but by arrangement of the American Institute of Physics it will be possible for subscribers in North America to pay their subscription through that Institute. Authors wishing to submit papers in English, French, German or Russian are asked to send them to Dr. Evans or Prof. Fankuchen, Prof. Wyart, Prof. Ewald, and Prof. Shubnikov, respectively, according to the language used.

Council for the Promotion of Field Studies

The Council for the Promotion of Field Studies announces that it has gratefully accepted the generous offer of the Court of the Worshipful Company of Goldsmiths to provide the sum of £6,000 for the establishment of a residential field study and research centre at Malham Tarn House, near Settle, Yorkshire. It is desired that the gift should be associated in name with the Goldsmiths' Company, and that a portion of it should be used to set up a rock and water garden for plants in their natural setting. Last year this property of 457 acres, including the tarn and tarn moss, came into possession of the National Trust, which offered to lease it to the Council. Malham Tarn House is situated in a district of great geological, ecological and archæological interest, and for certain branches of study the position of this field centre will be unique in the British Isles.

The Carnegie United Kingdom Trust, through the generosity of which the Council was enabled to open its pioneer field centre at Flatford Mill in 1946, has recently made a further grant of £5,000 to complete the establishment of that centre. Further centres are being established at Juniper Hall, near Box Hill, Surrey, and at Dale Fort, on the Pembrokeshire coast.

Prof. A. G. Tansley has accepted the office of president of the Council, and the executive committee has made the following appointments: Director and Secretary: F. H. C. Butler, Ravensmead, Keston, Kent; Warden of Flatford Mill Field Centre: E. A. R. Ennion; Warden of Juniper Hall Field Centre: G. E. Hutchings; Assistant Wardens: J. H. Barrett, E. J. Douglas, J. H. P. Sankey. A central office for the Council will be opened shortly in South Kensington.

Bradford Technical College

The application of the Bradford City Council to the University Grants Committee for the recognition of Bradford Technical College as a university college ranking for a Treasury grant has been refused. In communicating this decision, the University Grants Committee has stated that it considers the application of the term 'university college' to an institution primarily or exclusively technological in scope to be inappropriate and confusing; the distinction is not one of rank or status, but of kind. The Committee also pointed out that financial support for a college of which the primary function is technology is a matter for the Ministry of Education and not for the University Grants Committee. Following consideration of the report of the University Grants Committee at a meeting on June 18, Bradford Further Education Sub-Committee decided to seek an interview with both the Chancellor of the Exchequer and the Minister of Education to investigate further the possibilities of securing for the College university status.

"A Century of British Chemistry"

We have received "A Century of British Chemistry", by Dr. F. Sherwood Taylor, published for the British Council by Longmans, Green and Co., Ltd. (1*s*. 6*d*. net). This is intended to mark the centenary celebrations of the Chemical Society, which were due in 1941 but were postponed on account of the War (see *Nature* of July 5, p. 6). The booklet deals with the contributions of British men of science to various branches of chemistry during the century in which the Society has been in existence; but as no historically sound document could be produced on such lines alone, account has also been taken in some places of the contributions of other nations in initiating or extending chemical knowledge. The booklet includes plates of portraits and illustrations of apparatus of historical interest. There is an index.

History of Chemistry

The University of Pennsylvania Press is initiating an annual publication on the history of chemistry, entitled *Chymia*. A volume will consist of about a dozen articles, each of about 4,000–5,000 words, contributed by outstanding scholars from all over the world. The publication is sponsored by the Edgar F. Smith Memorial Collection at the University of Pennsylvania, a well-known collection of rare books, manuscripts, prints, and other items of interest in the development of chemistry. Publication will be under the direction of a board of American editors with a group of consulting editors, all of international prominence. The first number is ready for the press and will probably be issued this autumn. The Oxford University Press will publish *Chymia* in Great Britain. Requests for further information should be addressed to Eva V. Armstrong, secretary of the Board of Editors, Edgar F. Smith Collection, Harrison Laboratory, University of Pennsylvania, Philadelphia 4.

Non-industrial Civil Servants

In the detailed statement as to the number of non-industrial Civil Servants in departments with staffs of more than a thousand at April 1, 1947, circulated by the Chancellor of the Exchequer in *Hansard* of July 1 in reply to a question in the House of Commons, the staff of the Department of Scientific and Industrial Research is given as 2,248, as against 1,502 on April 1, 1939. The Forestry Commission now employs 1,334 as against 509, the Ministry of Agriculture and Fisheries 6,233 instead of 2,591, the Ministry of Education 2,898 instead of 2,078, the Ministry of Health 5,087 as against 6,676, the Department of Agriculture, Scotland, 1,376 instead of 659, and the Department of Health, Scotland, 1,013 in place of 991. The total is now 702,363 as against 382,709 in 1939; of this number 262,372 are in the Post Office. In the debate on the Post Office on the following day some reference was made to research, and the Assistant Postmaster-General stated that a house has been taken at Stone, Staffordshire, where a thousand engineers would be trained, some of whom have been at Dollis Hill. The accommodation thus released would be available for carrying out fundamental research, and by 1950 it is expected to have 150 fully qualified scientific men and engineers on such research. It is proposed to double the major engineering and scientific staff at Dollis Hill during the next few years.

Imperial Bureau of Pastures and Field Crops

As a result of a recommendation of the 1946 Review Conference of the Imperial Agricultural Bureaux, the Imperial Bureau of Pastures and Forage Crops now becomes the Imperial Bureau of Pastures and Field Crops (director, Dr. R. O. Whyte). In its expanded form it will cover that part of the literature on the following crops not already the concern of the Bureaux of Plant Breeding and Genetics, or Soil Science: all cereals, field root-crops, pulses, groundnuts, cotton and other fibre crops grown on a field scale, sugar beet and sugar cane, in addition to the literature on grassland management and fodder production which has been the concern of the Bureau for the past seventeen years. Attention will continue to be given to those aspects of plant biological research which refer to the crops now covered, and sections will now also deal with farming systems concerned in the production of field or forage crops, and certain economic aspects of crop and fodder production.

Although the name of the Bureau has been changed to Pastures and Field Crops and a second abstracting journal (in addition to *Herbage Abstracts*) is to be published from 1948 onwards, it will be some time before it will be possible to claim that the extended field of research and practice is being adequately covered, or before it will be possible to reply without a little difficulty to inquiries on the new crops now added to the Bureau's responsibilities. Those concerned with these crops should send their publications and reports to the Imperial Bureau of Pastures and Field Crops, Penglais, Aberystwyth, Wales, for review in the new abstracting journal dealing with field crops. Particulars of this journal will be sent to persons interested.

University of Birmingham

The University of Birmingham has created a chair of gastroenterology and has appointed as its first occupant Dr. T. L. Hardy. Dr. Hardy was one of the founders of the British Society of Gastro-enterologists in 1938.

Dr. J. F. Brailsford, who is well known as a radiologist, has been appointed honorary director of radiological studies in living anatomy. Dr. Brailsford was the first radiologist to be elected Hunterian professor of the Royal College of Surgeons, and is a former president of the British Association of Radiologists.

Four members of the University have been appointed to professorial chairs overseas: Dr. F. Smith, reader in the Department of Chemistry, to the chair of chemistry in the University of Minnesota; Mr. N. M. MacElwee, lecturer in electrical engineering, to the chair of electrical engineering in University College, Christchurch, N.Z.; Dr. T. G. Hunter, of the Chemical Engineering Department, to the chair of chemical engineering in the University of Sydney, Australia; and Dr. F. J. Llewellyn to the chair of chemistry in the University of Auckland, N.Z.

At the annual degree congregation, the Chancellor (Mr. Anthony Eden) conferred the honorary degree of doctor of science on Dr. Otto Robert Frisch, director of the Nuclear Physics Section of the Atomic Energy Research Establishment at Harwell, newly appointed Jacksonian professor of natural philosophy in the University of Cambridge. The degree of doctor of science was conferred on the following: F. A. Fox (metallurgy), J. K. N. Jones (chemistry), J. H. Partridge (metallurgy), W. T. Pell-Walpole (metallurgy), and L. F. Wiggins (chemistry).

A presentation was made to Prof. J. G. Smith, after twenty-eight years service to the University, on his retirement from the post of vice-principal. Prof. Smith is succeeded as vice-principal by Sir Norman Haworth, professor of chemistry in the University.

Announcements

In connexion with the centenary celebrations of the Chemical Society, the University of London has conferred honorary degrees on the following: Prof. C. N. Hinshelwood, Dr. Lee's professor of chemistry in the University of Oxford (president of the Chemical Society); Prof. J. N. Brønsted, professor of chemistry in the University of Copenhagen; Prof. P. Karrer, professor of chemistry in the University of Zurich; Prof. L. C. Pauling, professor of chemistry in the California Institute of Technology.

Prof. G. H. Hardy, emeritus professor of pure mathematics in the University of Cambridge, and Dr. A. F. Blakeslee, honorary professor of botany at Smith College, Northampton, Mass., have been elected foreign associates of the Paris Academy of Sciences.

Sir Edward Appleton, Sir Alexander Fleming and Sir Arthur MacNalty have been elected honorary fellows of the Royal Society of Edinburgh.

Dr. David Heron has been elected president of the Royal Statistical Society in succession to Lord Woolton. Prof. J. H. Jones, emeritus professor of economics in the University of Leeds, has been elected honorary treasurer.

The following appointments in the University of Sheffield have been announced: Dr. D. H. Peacock, lecturer in chemistry; C. Hulse, lecturer in fuel technology; H. D. Bush, assistant lecturer in physics; J. M. Thoday, assistant lecturer in botany and zoology (for cytogenetics); Dr. D. B. Leason, research assistant in fuel technology. Dr. R. Rado has resigned from the post of lecturer in mathematics.

Quantitative Estimation of Mixtures of Sugars by the Paper Chromatogram Method

MODERN developments in the chemistry of the polysaccharides have served to increase the importance of the problems of identification and estimation of mixtures of sugars. In many cases the mixture of sugars resulting from hydrolysis of a polysaccharide is so complex as to render analysis by orthodox methods difficult. These have depended mainly on precipitation by a specific reagent and deal usually with quantities of the order of 200 mgm. of each individual sugar. There is an urgent need, therefore, for a method which would permit separation and facile estimation of complex mixtures, and would be capable of dealing with the very small quantities which are obtained in many biological studies.

A remarkable advance on the qualitative side has recently been described by Partridge[1], who has developed an application of the paper chromatogram[2] to the separation of exceedingly minute amounts of sugars. Using a similar technique, we have now elaborated a method for the quantitative determination of the separated sugars, and we are able to analyse qualitatively and quantitatively mixtures containing several sugars with an accuracy of ± 5 per cent. The total quantity of material used in the analysis is less than 1 mgm.

For the quantitative estimation of the sugars separated on the chromatogram, Somogyi's micro-copper reagent[3] has been used. An alternative procedure consists of measuring by a colorimetric method[4] the formaldehyde produced by oxidation of the sugars with periodic acid. The micro-copper reagent will deal with quantities of sugar ranging from about 0·05 mgm. to 5·0 mgm., these amounts varying slightly with different sugars. In order to obtain amounts of sugar on the paper chromatogram falling within this range, as many drops of solution (of equal size) as are required to make up this quantity are placed side by side on the starting line of the chromatogram. In general, two paper sheets were used, measuring approximately 60 cm. by 10 cm. One of the end spots is well separated from the others, so that after chromatographing and drying off the solvent, a narrow strip containing this end spot can be cut from the original paper sheet and the position of the sugars determined by spraying with ammoniacal silver nitrate, a preliminary qualitative identification of the sugars having already been made on another chromatogram. The rest of the paper can then be divided into corresponding sugar zones by reference to the small sprayed strip. At the same time, equal areas of paper are cut from the same major sheet to serve as paper blanks.

After the sheet has been cut, the strip of paper containing the sugar is suspended by platinum wire from the lower coil of a ground-glass spiral condenser to which is attached by a ground-glass joint a boiling-tube containing water. All further operations are carried out in this tube, so that no transfer of liquid is necessary. It has been found that the sugars can be extracted quantitatively by refluxing water in this apparatus. At the same time, an exactly identical procedure was carried out with the appropriate paper blank.

In order to obtain consistent results with the copper reagent, it was found essential to analyse at the same time a standard solution of the particular sugar under identical conditions. By this means it is possible to arrive at a sugar-weight corresponding to each titration figure, and in this way the sugar ratios can be determined.

In some cases where it is known with certainty that the sugars determined comprise the sum total of polysaccharide, it is sufficient to convert the ratios to percentages. More often, however, partially hydrolysed components may be present which would make this device unjustifiable. This difficulty is readily surmounted by weighing into the hydrolysate a sugar known not to be originally present and having a R_F value markedly different from the sugars to be estimated. This serves as a reference compound, and a knowledge of the various ratios now leads directly to absolute weights.

For example, using this procedure we have been able to estimate satisfactorily the components present in a mixture containing respectively galactose and rhamnose; glucose, xylose and arabinose; and galactose and arabinose. These groups were chosen specially on the ground that they are of frequent occurrence in plant gums and other similar materials, and offer very serious analytical problems by ordinary methods. As a particular example of a difficult mixture, results obtained with rhamnose and arabinose are given in detail in the accompanying table.

		Sugar weighed out (mgm.)	Found by titration (mgm.)	Calculated from reference compound (mgm.)	Recovery (per cent)
To be estimated	Rhamnose	9·60	0·261	9·22	96
To be estimated	Arabinose	5·80	0·157	5·54	95·5
Reference compound	Glucose	4·38	0·124	—	100 (assumed)

As a further example of the scope of the method, reference may be made to its application to an analysis of the sugars present in Cholla gum (from *Opuntia fulgida*). Qualitative chromatographic analyses revealed the presence of *l*-arabinose, *d*-xylose, *d*-galactose and a uronic acid. Quantitative chromatographic analysis, together with an estimation of the uronic acid content by a micro-method, showed that the sugars and uronic acid are present in the polysaccharide in the ratio of 6 : 2 : 3 : 1 respectively. Investigations by Mr. Fred Brown using the normal procedure of methylation and hydrolysis on the macro-scale had earlier revealed the same proportion of sugars to be present in the gum.

Furthermore, we have succeeded in separating mixtures of methylated sugars and are applying the method to end-group determinations on a micro-scale. Using petrol ether, b.p. 40°–60° (specially purified), as the mobile phase in the chromatogram, it is possible to separate a dimethyl pentose from a trimethyl pentose, while *n*-butanol permits the separation of a trimethyl hexose from a tetramethyl hexose. The sugars can be isolated and estimated as before, except that in these cases the periodate-formaldehyde method is not applicable.

The qualitative separation has also been made applicable to the simple mono- and di-carboxylic acids and is being extended to cover the sugar acids.

It is apparent that the method should be of wide application as a micro-method of investigation in the carbohydrate group.

Colour of Iodine Solutions

The dependence of the colour of iodine solutions upon the nature of the solvent is generally believed to be due to the presence of loosely bound iodine-solvent complexes, or 'solvates', in the brown solutions (for example, in ethanol) and of 'unsolvated' diatomic iodine molecules in the violet solutions (for example, in carbon tetrachloride)[1]. The nature, however, of this 'solvation' remains obscure. It is obviously not a simple electrostatic solvation, for it has little to do with the dielectric constant of the solvent; nor would such a solvation serve to account for the marked difference in chemical properties between the violet and brown solutions.

An explanation may be found in the amphoteric nature of iodine. There is some evidence to show that the symmetrical ionic structures $Hal^+.Hal^-$; $Hal^-.Hal^+$ may contribute more to the actual normal state of the halogen bond, especially in bromine, and still more in iodine, than has been commonly supposed. Moreover, since the univalent positive iodine ion contains an unoccupied $5p$ orbital in the free state, the proximity of an electron-donor, for example, an oxygen, sulphur or basic nitrogen compound, would stabilize one of the ionic structures and thus destroy the electrical symmetry of such an iodine molecule, bringing about what is, in effect, a partial ionization of the iodine, with the positive end of the molecule stabilized by co-ordination with the donor molecule. The essential difference, therefore, between a violet solution and a brown one is that whereas in the former the iodine is present as symmetrical non-polar diatomic molecules, in the latter the iodine molecules are polarized by co-ordination with an electron donor molecule.

That it is principally the electron-donor character of the solvent and not its dipolar character which is operative is shown by the fact that iodine forms brown solutions in very weakly polar solvents which have some donor character, but violet solutions in such strongly polar solvents as nitro-compounds, which have little or no donor or 'basic' properties.

This theory is supported by the magnitude of the dielectric polarization of iodine in violet and brown solutions respectively. A new series of measurements has been made, and is being extended, of the dielectric polarization of iodine in a number of solvents of small or zero polarity and in the presence of electron-donor groups. The results, details of which will be published in due course, leave no doubt that the formation of a red or brown solution of iodine is accompanied by a polarization of the molecule. For example (to the nearest $0 \cdot 1\ D$), the *apparent* dipole moment of iodine in benzene (reddish-violet solution at 25°) is $0 \cdot 6\ D$, in *p*-xylene (deeper red), $0 \cdot 9\ D$, in 1 : 4-dioxane (brown), $1 \cdot 3\ D$, and in di-isobutylene (red-brown solution), $1 \cdot 5\ D$.

No less interesting, however, than this solvolytic ionization of iodine itself is the light which it throws on the donor or basic properties of aromatic and ethylenic hydrocarbons.

A similar explanation to that offered above may without doubt serve also to account for the parallel phenomena of the dichroism observed in solutions of iodine monochloride and iodine monobromide[2,3].

Partition Chromatography of Organic Acids on a Paper Sheet Support

By so-called 'one-dimension partition chromatography' on a paper support (first used successfully by Consden, Gordon and Martin[1] for the separation of amino-acids, and recently adapted by Partridge[2] for the separation of reducing sugars), we have succeeded in separating the individual members of a mixture of carboxylic acids of the types commonly occurring in plant tissues.

Attempts to exploit this sort of procedure, with water as the fixed phase in the paper and a neutral mobile phase (*n*-butanol), were unsuccessful for the following reasons. (*a*) From the positions at which the 'spots' of aqueous solutions of the individual acids were applied to the paper, the acids left long, diffuse 'tails' behind the 'heads' as the heads travelled down the paper with the mobile phase; and, moreover, (*b*) the excursions of the heads were found to vary with the concentrations of the acids, being less at the lower concentrations. The diffuse tails made it impossible to separate the members of a mixture, and the variation of excursion with concentration precluded the possibility of identifying an acid by the excursion of its head relative to the excursion of the mobile phase.

Under the above conditions of experimentation, it is possible that the acids are adsorbed to some extent by the paper. Be that as it may, a serious difficulty must, in any event, arise from the increase in dilution of an acid in the neighbourhood of the initial spot as it is withdrawn therefrom into the mobile phase for transmission down the paper. From consideration of the dielectric constants of water and of *n*-butanol, it is reasonable to suppose that the 'gross' partition of an acid between the aqueous and the mobile phase will change markedly in favour of the aqueous phase as dilution proceeds. The diffuse tails and the reduction in extent of excursion with reduced concentration of the acids in the applied spots are, therefore, to be expected, even if adsorption of the acids by the paper is not an important factor.

One method of overcoming the difficulty is to use, as mobile phase, a solvent strongly acidified with a volatile acid. The mobile phase (we have used *n*-butanol saturated with aqueous acetic acid solution, and containing 1 or 2 moles of acetic acid per litre of the phase) may be removed afterwards, together with much of the aqueous phase, by exposing the paper sheets to the air for many hours or by drawing over them in a drying cabinet a current of warm air (up to 60° C.) for an hour or so. We prefer to remove most of the volatile material by a brief run in the cabinet, and complete the removal by exposing the sheets to air at room temperature for several hours.

We spray the dried sheets with a suitable *p*H indicator solution and then re-dry them. A solution of 40 mgm. of brom-phenol-blue (or of brom-cresol-green) in a mixture of 95 ml. of ethanol and 5 ml. of water and adjusted to a purple tint corresponding with *p*H 5·0 in water (or blue with the second indicator) corresponding with *p*H 5·5 in water) is satisfactory for most purposes. The positions of the individual acids are then revealed by yellow spots on a purplish-blue (or greenish-blue with the second indicator) ground.

The spots have slight tails but are reasonably well defined. The R_F values (that is, the ratios of the excursions of the spots from the initial positions, to that of the front of the mobile phase from the same positions) appear to decrease slightly with decrease of concentration of the acids.

By excising the areas of paper enclosing the spots, steeping in water and titrating with dilute alkali between selected *p*H values, we have obtained rough estimates of the quantities of the acids in the solutions initially applied. Blanks are determined on excised areas of paper (over which the mobile phase has run) which are free from the spots.

The aqueous phase is established in the paper by exposing it in the chromatography tank to vapour from the aqueous volatile acid solution which has been used to saturate the mobile phase. The mobile phase is run over the paper from a trough in the manner described by Consden, Gordon and Martin[1] (that is, by capillarity). We have used Whatman No. 1 filter papers (22 in. × 18 in.). The volumes of acid solutions applied as initial spots have been 0·02 ml. Mixtures of 20 μgm., each of malic, tartaric and citric acids, have been resolved with ease. The period of a chromatographic run has varied from 18 to 40 hours, at about 17° C.

In our view, the essential chromatography problem was to suppress the ionizations of the acids in both phases, particularly in the fixed phase wherein (water comprising most of the phase) they would be extensive at low concentrations in the absence of a high concentration of hydrogen ions from another source. Whether adsorption of the acids by the paper constituted a serious problem in our initial experiments, we do not know. This problem, to whatever extent it may have existed, was probably solved jointly with the ionization problem, at least to the present state of satisfaction, by 'swamping' with the volatile acid.

A limitation to this application of partition chromatography is imposed by the fact that the acids concerned in the study should be of sufficiently low volatility to remain on the paper during exposure in the chromatography tank and during the subsequent removal of the volatile acid.

Work is proceeding with organic acids of general interest in plant and animal metabolism, on the use of other mobile phase solvents and formic acid as the volatile acid, and on 'two-dimension' partition-chromatographic[1] separations. It is our intention to publish a more detailed report of the work later.

Mercurochrome as an Indicator in Acid–Alkali Titrations

It has been found that, in an alkaline solution, mercurochrome (disodium-dibromo-hydroxy mercury fluorescein) exhibits fluorescence which disappears as soon as the solution reaches the neutralization point during its titration with an acid. It then becomes markedly red as the solution becomes acid, there being now no fluorescence.

This change was equally clearly marked in the case of natural waters even with low alkalinity, and the results were identical with those obtained when methyl orange was used as an indicator. When solutions of potassium hydroxide, sodium carbonate or sodium bicarbonate were titrated against a standard acid, the use of mercurochrome as an indicator gave exactly the same results as methyl orange.

Even when the titration of sodium carbonate with an acid was begun with phenolphthalein as an indicator and completed with mercurochrome, instead of methyl orange, the results were the same.

The same change in the reverse order was observed with equal exactness while passing from an acid solution, through the neutralization point to alkaline solution.

One drop of a 1 per cent aqueous solution of mercurochrome was employed throughout.

A New Colour Reaction for the D Vitamins

While making a comparative study of the colour reaction of steroids and triterpenes, we have found a hitherto undescribed reaction produced by the D vitamins, producing a clear and limpid blue colour which we think might be used for quantitative estimations. We carry out Pettenkofer's reaction for the biliary acids as follows: to 1–2 mgm. calciferol is added 1–2 mgm. saccharose, and the whole is dissolved completely in 1–2 c.c. of absolute ethanol. Then we add two drops of concentrated sulphuric acid, giving a red colour; then six drops of sulphuric acid are added, giving a stark blue colour. The test-tube is shaken to mix the two layers. The colour diffuses throughout the liquid, and the definitive colour is a pale limpid blue.

The intensity of the colour increases within the first fifteen minutes; thereafter it becomes stabilized as a sky-blue colour. The coloration obtained seems to be in a direct relation to the concentration, that is, according to Beer's law.

Ergosterin in similar conditions gives a clear violet colour.

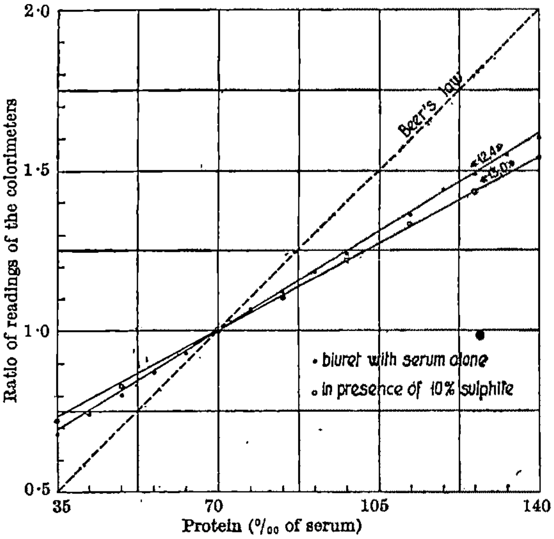
An Improved Biuret Reaction of Proteins and the Two-Standard Colorimetry

MEHL announced in 1945 [1] that by the use of ethylene glycol an alkaline copper reagent could be prepared in which copper, besides not being precipitated, could give the biuret reaction. At the high proportion in which glycol enters into Mehl's reagent, the presence of reducing impurities made it necessary to prepare the reagent in two stages, heating in order to speed up the reaction, and filtering in order to remove the precipitated copper. Nevertheless, the presence of the colour of the alkaline copper reagent causes the reaction to depart considerably from Beer's law; Mehl deduces from a spectrophotometric analysis that, starting from the 750 mμ and 545 mμ absorptions, the quantity of proteins present can be approximately calculated.

We have found that glycerine gives a better reagent for the biuret reaction than glycol, for the following reasons: the glycerine required is only a hundredth of the amount of glycol and there are no reducing impurities, thus making it possible to prepare the reagent in one stage.

This reagent is prepared by mixing 2 ml. of glycerin, 80 ml. of 5 per cent copper sulphate ($CuSO_4.5H_2O$) and 400 ml. of 20 per cent sodium hydroxide, and adding water up to 1 litre. This reagent is mixed, volume for volume, with the liquid under investigation (water being added if it is necessary in order to bring the final concentration of proteins to the value of about 1–2 °/₀₀).

As regards the colorimetric valuation, we have found that it is possible by visually compared colorimetry using our two-standard colorimetry system[2]; although theoretically it should not be possible, as it is an 'impurity' which varies according to the intensity of the reaction. It is interesting to note that the interference of sodium sulphite at half the concentration corresponding to the precipitation of globulins can also be removed by two-standard colorimetry.



The accompanying graph records two sets of experimental data giving serum proteins as parts per thousand of serum (the final concentration of the same being about 2 per cent). The slight deviations from the straight lines which represent particular cases in our general equation of compared colorimetry[3] do not prevent the practical determination of serum proteins. The increased deflexion caused by the sulphite comes fully into the field of utility of two-standard colorimetry.

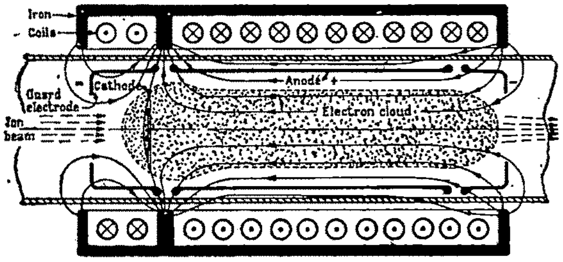
A Space-Charge Lens for the Focusing of Ion Beams

SOME time ago I proposed a magnetron of special design as a divergent lens for electron beams[1]. It now appears that the same device may become useful as a very powerful concentrating lens for positive ions, particularly for ion beams of extreme energy.



MAGNETRON LENS FOR ION BEAMS

In the design shown in the illustration, a magnetic field is produced by two coils of uneven length, in opposition. A hot cathode in the form of a circular loop is arranged at or near the magnetic field-line which crosses the axis. This arrangement is necessary, as electrons which have to cross magnetic flux lines are prevented by their angular momentum from reaching the axis. In the region where the magnetic field is approximately axial and homogeneous, a cylindrical electrode, the 'anode', is arranged, with high positive potential with respect to the cathode. So long as the anode potential is below a certain critical value, the magnetic field prevents all but a small fraction of the electrons from reaching the anode. At the two ends, guard electrodes with potentials somewhat below the cathode potential prevent the electrons from escaping. Thus the space accessible to electrons is limited from all sides, and will have an outline approximately as shown in the figure. Into this space the cathode will pour electrons, until the potential in the axis is depressed to very nearly cathode potential, and equilibrium is established.

According to the theories of Hull[2] and Brillouin[3], in the steady state the electrons rotate around the axis in equilibrium orbits, such that the electrostatic repulsion of the electrons inside the orbit together with the centrifugal force balance the radial Lorentz force produced by the magnetic field. The electron distribution in the cloud is uniform, with a space-charge density

$$\rho_H = -\frac{eH^2}{8\pi m_e c^2}, \qquad (1)$$

where $-e$ is the charge and m_e the rest mass of the electron. I have shown[1] that if the assumption of equilibrium orbits is valid, an electron shot axially through the magnetron will be also in radial equilibrium, that is to say, the lens effect is nil, apart from a relativistic effect. My previous suggestion, to use the magnetron as a divergent electron lens, was based on departures from the Hull–Brillouin steady state. Such departures were expected on the basis of my statistical theory of the electron cloud[4], in which radial equilibrium does not obtain at every instant but only over long intervals. It was pointed out at that time that neither the Hull–Brillouin theory, nor mine, is likely to apply under practical conditions, as both neglect electron interaction. But in the case of ion beams these differences can be disregarded, and equation 1 can be adopted, at least for a first orientation.

The radial forces of magnetic origin on ions of mass m_i are only a fraction m_e/m_i of the corresponding forces on an electron, and can be neglected compared with the radial electrostatic force, produced by the space charge, which retains its magnitude and merely changes its sign. The electric field intensity E_r at the radius r is

$$E_r = 2\pi r \rho_H = -\frac{eH^2}{4m_e c^2} r = -0{\cdot}044\, H^2 r \text{ volt/cm.} \quad (2)$$

The field is of the type required for lenses, as it increases linearly with the radius. Using the relativistic equation for the radial motion, the focal length f of a magnetron lens of length L is given by

$$\frac{1}{f} = 0{\cdot}022\,\frac{1 + 1{\cdot}06 \times 10^{-9} V/M}{1 + 0{\cdot}53 \times 10^{-9} V/M}\,\frac{H^2}{V}\,L \text{ cm.}^{-1}, \quad (3)$$

where V is the volt-energy of the ion, supposed to be single-charged, and M is its molecular weight.

As an example, consider a lens with $H = 500$ gauss and $L = 20$ cm., which requires about 8,000 amp. turns. If the radius of the anode cylinder is 2 cm. the critical voltage is 22 kV., and in practice perhaps 15 kV. may be applied before the anode current becomes noticeable. For 100 MeV. protons, that is, for $M = 1$, $V = 10^8$, equation 3 gives a focal length of 8·7 metres. By comparison, if the same coil were used, by itself, as a concentrating lens for 100 MeV. electrons, the focal length would be about 900 metres. The advantage is even greater at higher energies, as f in the new magnetron lens increases with V, as compared with V^2 for magnetic lenses and V^4 for electrostatic 'single' lenses. The only other lens types which share this advantage with the magnetron lens are the 'field lens' of L. W. Alvarez, in which the electric field terminates on a metal foil, its equivalent, recently investigated by me[5], in which the foil is replaced by a mesh grid, and the magnetic toroidal lens, recently proposed by W. T. Harris[6].

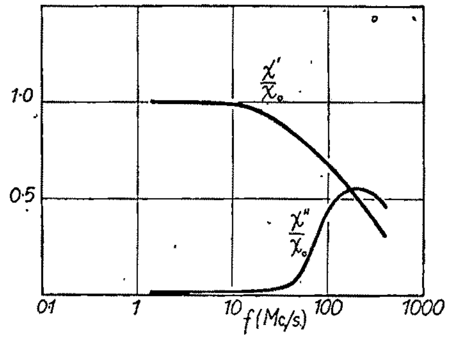
Gyromagnetic Resonance in Ferrites

Magnetic ferrites of great homogeneity have been prepared in this Laboratory. In these ferrites the tangent of the loss angle between B and H is found to rise at a certain frequency fairly suddenly from values less than 1 per cent to values much exceeding unity. The permeability at the same time goes down to very low values, which shows that not only the boundary displacements but also rotation of domains as a whole are affected at these frequencies. The behaviour of the complex susceptibility $\chi_c = \chi' - i\chi''$ (see graph) suggests a phenomenon of resonance.



According to calculations made by L. Landau and E. Lifshitz[1], gyromagnetic resonance may be expected to occur in a ferromagnetic dielectric, if the frequency of the applied field equals the precession frequency of the spins around the direction of the internal field. In Landau's model the specimen is assumed to be a single crystal and the applied field is at right angles to the crystal field. Our experiments, on the other hand, were carried out on polycrystalline samples. Nevertheless, it is worth while comparing Landau's formulæ and our experimental results.

Assuming that the precession is critically damped, one easily derives from Landau's equations the following relation between the transverse susceptibility χ_t, the frequency f_h, for which the real part of the susceptibility is halved, and the saturation magnetization $I_{\max}$:

$$\frac{\chi_t \cdot f_h}{I_{\max}} = \frac{\sqrt{2}}{2\pi} \cdot \frac{e}{mc} \cdot 4 \times 10^6 \text{ cycles/Oe. sec.}$$

Evaluation of χ_t, f_h and $I_{\max}$ for the polycrystalline sample, the properties of which are shown in the graph, leads to

$$\frac{\chi_t \cdot f_h}{I_{\max}} = \frac{3{\cdot}5 \times 200}{400} \cdot 10^6 = 1{\cdot}75 \times 10^6 \text{ cycles/Oe. sec.}$$

In our opinion the approximate agreement between theory and experiment warrants the conclusion that the rapid decrease of μ_0 in ferrites at high frequencies is probably due to gyromagnetic resonance around directions prescribed by the internal fields.

Evaporation of Meteors

THE publication of radar photographs in *The Times* of October 11, 1946, and also in *Nature* on December 28, has brought the question of ionic clouds again to the fore. There is no evidence that the photographs are of visible meteors. They are probably of clouds of electrons at or near the E-layer, usually known as 'scatter clouds'. Visible meteors move. These do not, as was pointed out in the note in *The Times*. (By visible meteors, I mean large meteors which would be visible to the naked eye if there were no ordinary cloud obstruction.) The second photograph in *Nature* of December 28 is, I think, a secondary effect of a meteor shower. We have, in fact, a photographic record taken on November 15, 1937, showing occasions on which visible meteors have produced no scatter cloud for longish wave-lengths between 32·35 and 16·13 metres. The picture in *The Times* may be of scatter clouds produced by invisible meteors evaporating; but it should be noted that meteors are by no means the only cause of scatter clouds, which may equally well be produced before Dellinger 'fades'. We have considerable evidence of this.

The second *Times* photograph may be considered as evidence of an invisible meteor shower. But with regard to the increase in this photograph, taken at 3.40–3.50 a.m., in comparison with the first photograph, taken at 9.15–9.25 p.m. on the previous day, it has been shown that there is always a peak of about three to six to one at about this time, whether there is a meteor shower in progress or not.

A theory which will account for all the effects is as follows: it is supposed that scatter clouds can be produced by small meteors evaporating. (If they are small enough, they do evaporate at great heights. The larger they are, the lower the height at which they will evaporate.) The amount of energy supplied is proportional to the area swept out by the meteor. The amount of energy required to evaporate it completely is proportional to its volume. Thus there must be a size at and below which the energy supplied is greater than that required, and small enough meteors will evaporate, producing scatter clouds. It is probably these scatter clouds which *The Times* photograph shows, and not visible meteors.

The fundamental idea which makes a complete understanding possible is published in "Studies in Radio Transmission"[1]. It is this: that there is a very close analogy between the scattering of radio waves from scatter clouds and the scattering of alpha particles from heavy molecules. This leads to the Rutherford fourth-power law. The ratio of the scattered to the primary signal E/E_0 for a constant number of particles is proportional to $(\lambda/a)^4$, where a is the radius of the cloud. It is thus only the small clouds which scatter effectively, and not the big clouds. The big clouds are visible meteor trails. The small clouds are the evaporating invisible meteors, and it is these that we see in the radar photograph. The fourth-power law for λ has been checked experimentally and theoretically, and I think there is no doubt about this. According to this explanation, the whole of the results are intelligible.

Chromatic Correction of Wide-Aperture Catadioptric Systems

IN the Schmidt camera system, where the spherical aberration of a mirror for a selected wave-length of light may be completely corrected by a suitably figured plate at the centre of curvature, there remains a chromatic variation of spherical aberration which sets a limit to the performance on the axis and for small angles of field, and which, for large relative apertures, becomes undesirably large. The effect is commonly reduced by introducing first-order axial chromatic aberration by using a corrector plate in the form of a figured lens of finite power instead of a figured plane parallel plate, the form in which the axial and marginal thicknesses are equal being not far removed from the optimum. Fig. 1 shows the departures (measured in d wave-lengths per 25 mm. of focal length) of the C and g emergent wave-fronts from the spherical d wave-front for a Schmidt system of relative aperture $f/0\cdot7$, using for the corrector plate a borosilicate crown glass, $n_d = 1\cdot516$, $V = 64\cdot1$, the maximum aberration for g being 1·5 wave-lengths when the marginal and intermediate zonal errors are equalized. The chromatic difference of spherical aberration is, of course, of the sign corresponding to an increase of glass-path with increasing aperture.

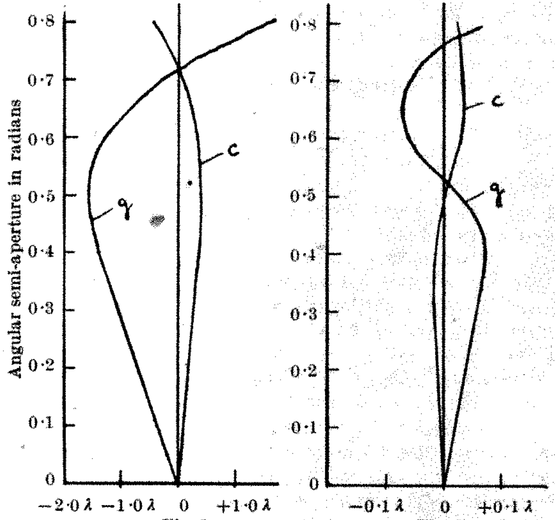

Fig. 1 Fig. 2

ABERRATION OF THE EMERGENT WAVE-FRONTS FOR C AND g PER INCH OF FOCAL LENGTH WITH RESPECT TO THE SPHERICAL WAVE-FRONT FOR $f/0\cdot7$ SYSTEMS

In the systems in which one or more spherical-surfaced meniscus lenses are used to correct the mirror aberration[1,2], the chromatic difference of spherical aberration is of similar magnitude to that of Schmidt systems, but of opposite sign, since the paraxially achromatic meniscus has an effective glass-thickness decreasing with aperture; this is normally minimized by introducing first-order axial colour of opposite sign to that used in Schmidt systems, resulting in curves practically identical with those in Fig. 1 but in the reverse sense. This fact, which does not appear to have been noted hitherto, obviously offers the possibility of a very considerable reduction of the residual chromatic aberrations by a combination of the two forms of corrector.

Preliminary calculation of an $f/0\cdot7$ system consisting of two menisci concave to, and on each side of, the mirror centre with a figured aspheric corrector plate between them shows that the colour errors may readily be reduced to one twentieth of that of either the Schmidt or two-meniscus systems; the corresponding curves for C and g are shown in Fig. 2, on a scale ten times that of Fig. 1. Such a lens has much thinner menisci than are necessary in the two-meniscus systems previously described[2]. The monochromatic oblique aberrations are, of course, not so good, though better than in the corresponding Schmidt, since the figuring on the plate is only about two thirds as great. For small angles of field this type of system would appear to offer pronounced advantages where very large apertures and considerable focal lengths are required.

Further investigation is in progress and a fuller account may be published later.

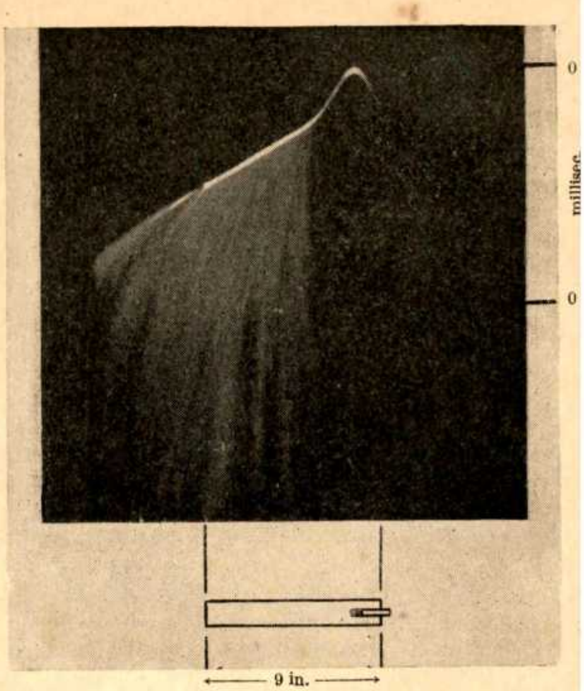
Speed Around the Initiating Point of the Detonation Wave in High Explosives

IN a recent communication[1], Weibull describes an interesting experimental technique and discusses the establishment of detonation in charges of compressed T.N.T., initiated by a No. 8 compound detonator; it would seem, however, that a general conclusion is drawn from these experiments, one which is not justified by their scope.

The conclusion, that there is no pre-detonation phase, applies only in special cases, and it does not accord with general experience either with solid explosives or with gaseous mixtures in which detonation is possible. The initiation of detonation in a charge of explosive is controlled by several factors, notably the sensitivity of the explosive and the strength of the initiating source. The accompanying reproduction is a record, taken by C. A. Naylor with the Buxton rotating-mirror camera, of the inception of detonation in a cylindrical charge, 1¼ in. diameter, of powdered tetryl, of density 1·10, initiated by means of a No. 6 detonator. This initiator was not strong enough to ensure immediate detonation, and the pre-detonation phase lasted until the explosion had traversed nearly one third of the cartridge; detonation was then set up, the rate being 4,680 metres per second. With progressively stronger initiators the extent of the pre-detonation phase was correspondingly reduced and the rate of propagation during this phase was increased, until, finally, there was no perceptible delay in the inception of detonation.

Thus, in border-line cases, it might be difficult to detect the establishment of detonation, and it is not felt that the photographic technique described by Weibull could decide this point with certainty, especially with high-rate explosives, for the method is not capable of the precision necessary for differentiating between speeds differing by less than 200–300 metres per second; the time-scale of photographic records of this nature cannot be read to a greater accuracy than 0·01 mm., which with a film speed of only 100 metres per second (0·1 mm. per microsec.) gives rise to an appreciable error when the quantity being measured is the *difference* between



the times taken by two wave fronts advancing at similar rates (about 6,800 metres per second) to travel distances which differ only by 0–3·2 cm.

Most important, however, is the fact that it is not possible to decide whether or not an observed 'explosion' developed under special experimental conditions is being propagated as a true detonation wave at the appropriate rate until this rate has been actually measured for the particular explosive as made up and used. For the rate of detonation depends on the nature and physical state of the explosive and also upon the conditions under which it is fired; for example, with a crystalline explosive like T.N.T., the rate depends on the crystal size and on the bulk density; within certain limits it depends also on the degree of confinement and on the size of the charge. It is possible also that there is a real though small difference in the rates of detonation, (1) during the initial stage when the wave is spreading spherically from the source to the bounding surface of the charge, and (2) when the wave is being propagated as a more or less plane wave through the remainder of the charge.

Weibull concludes that he is dealing with detonation only in so much as the velocity deduced from his experiments is 7,470 metres per second, a value some 700 metres per second higher than that given by Stettbacher[2] as the rate for T.N.T. (at a density of 1·62) and which, Weibull suggests, is at fault, though he fails to specify the density of his own charges. In our wide and varied experiments with T.N.T., the maximum rate ever measured over a long single cartridge (density 1·62) is nearly 6,950 metres per second; and it is suggested that the higher speed inferred by Weibull from his indirect records is due to the fact that he applied a technique to the measurement of phenomena far beyond its limits of accuracy.

There remains an old, and not yet explored, suggestion that the velocity of detonation of a crystalline explosive might be found to differ along different axes of a crystal. In a pellet of compressed

T.N.T., where the small crystals are irregularly disposed, this factor would not arise. But in a cast charge in which the crystal growth was carefully controlled, there might be detectable differences depending upon the orientation of the crystals with respect to the direction of propagation of the detonation wave.

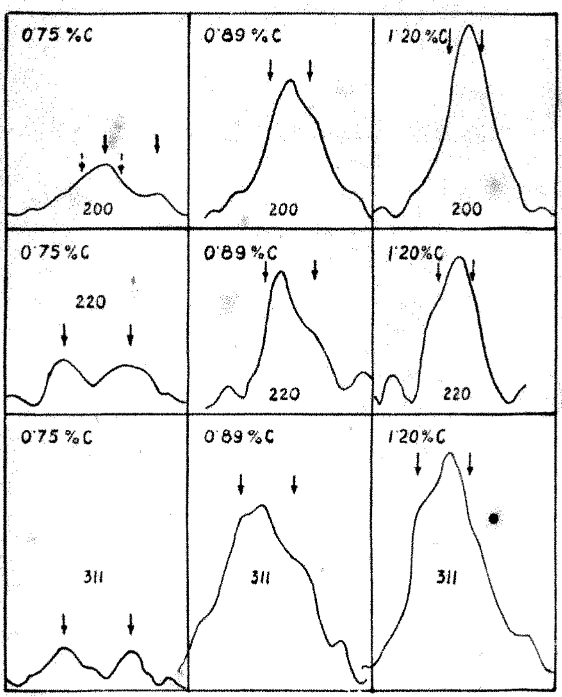
Structure of Retained Austenite in Plain Carbon Steels

THERE are many indications that retained austenite in quenched plain carbon steels should be regarded as a face-centred tetragonally distorted structure and not face-centred cubic as heretofore.

The tetragonality is shown either by pronounced broadening or distinct separation of the lines, depending on the carbon content in solution, that is, the amount of austenite. This is shown in the accompanying intensity curves of lines 200, 220 and 311 (photometer curves with uncorrected intensity and background equal to zero) of retained austenite present in quenched samples of steels with 0·75, 0·89 and 1·20 per cent of carbon. The shapes of these curves show that the tetragonality decreases with the increase of the amount of retained austenite.



By quenching iron–carbon alloys from the gamma modification the amount of the austenitic pseudophases, which have been called γG, γS, and γE[1], can be revealed. Since the grain in the above-mentioned quenched steels is made up of martensite and austenite, and since γS produces martensite and γE austenite, there is a strong 'linkage' between the two phases due to the sharing of iron atoms in the interfaces by both the austenite and the martensite.

The presence of martensite and austenite in phases differing in structure and parameter and linked closely together causes a tetragonal distortion of each with respect to the other. Martensite is tetragonally distorted in such a way that $c/a > 1$, whereas in distorted austenite $c/a < 1$. In the above-mentioned steels (0·75, 0·89 and 1·20 per cent of carbon), the tetragonality of retained austenite could as a first approximation be estimated as 0·9945, 0·9960 and 0·9975 respectively.

Further investigation is in progress, and it is hoped that more detailed discussion of some of the questions which emerge from the above finding will be published in due course.

Flow of Smoke through a Hole in Resonant Cavity

PROF. G. D. WEST[1] has used a smoke-filled cavity as a resonator and noted the stream of smoke issuing from a hole near the base; radiation pressure was suggested as a possible cause. In an alternative explanation[2], Prof. E. N. da C. Andrade suggests that air is simply expelled during one half-cycle in a definite smoke-laden stream, and is drawn in during the next half-cycle, air being sucked in from all sides.

The matter can readily be settled by reversing Prof. West's experiment. According to Prof. Andrade's explanation, smoke outside the resonator should appear to stream in just as readily as it streamed out in the original experiment. This has been done, and the effect has been found to be reversible.

A variation of Prof. West's experiment was made as follows: A length of 2 in. diameter transparent 'Plexiglass' tubing was made to resonate as a 'closed pipe' at its first overtone (the length of the pipe thus being three quarters of the fundamental wavelength). The system was driven by a moving-coil speaker mounted at the open end of the pipe and connected to an electronic oscillator operating at 500 cycles. Pinholes were drilled in the pipe at the two pressure antinodes and at the pressure node between them. When the tube was filled with smoke and the driving source switched on, it was observed that smoke rushed from the pinholes at the antinodes but did not issue from the node if this pinhole was carefully located.

The reverse experiment was then carried out. The tube was cleared of smoke and was made a resonator as before. A short piece of similar tubing was filled with smoke and fitted tightly to the first tube over each of the pinholes in turn, using 'Plasticine' to seal the connexion. Smoke was observed to rush into the resonating tube at both pressure antinodes.

Antagonistic Effect by Certain Growth-Stimulants of the Tuberculostatic Activity of 5-Amino-2-butoxypyridine

THE powerful inhibitory action of 5-amino-2-butoxypyridine on the growth of *Mycobacteria*, which is highly specific for members of that genus, has recently been reported[1,2]. Strains of *M. tuberculosis* (including the human-type *H37Rv*) and *M. phlei* were inhibited at dilutions of this compound so high as 0·03–0·001 mgm. per cent in Dorset's synthetic or in Proskauer–Beck medium, inoculation being either on the surface by a small piece of pellicle or by a suspension of about 20,000 organisms per ml.

As we had immediate access to the compound, in the form of the dihydrochloride, we have sought independent confirmation of these remarkable observations. We have used *H37Rv* (from the American depot at Trudeau Sanatorium, Saranac Lake) and a bovine-type strain *SB* (from Mr. R. E. Glover) as examples of *M. tuberculosis*, as well as a laboratory strain (*P*) of *M. phlei*. Growth was completely or almost completely inhibited at drug concentrations of less than 0·1 mgm. per cent under the following conditions:

(i) *Surface culture* of *H37Rv* in Proskauer–Beck medium, and of *P* in digest broth and in a modification of the synthetic basal medium of Dubos[3] (Difco Casamino acid, 2·5 gm.; asparagine, 0·3 gm.; anhydrous Na_2HPO_4, 2·5 gm.; KH_2PO_4, 1·0 gm.; sodium citrate, 1·5 gm.; $MgSO_4, 7H_2O$, 0·6 gm.; glycerol, 25 ml.; distilled water to 1 l.);

(ii) *Sub-surface culture* of *H37Rv*, *SB* and *P* in the synthetic basal medium, and of *H37Rv* in Proskauer–Beck medium, the inoculum being 0·04 mgm. moist weight of bacilli per 5 ml. medium in a 25 mm. diameter test-tube; *M. tuberculosis* surface cultures were read at 30 days, and sub-surface cultures at 14 days; *M. phlei* surface and sub-surface cultures were read at 4 days. In these findings we are in agreement with the American workers.

Addition of 0·25 per cent serum albumin (bovine plasma fraction V) to the Proskauer–Beck medium and to the broth had no apparent effect on the marked inhibition of growth of surface-cultured *H37Rv* and *P*, respectively. Such addition to the synthetic basal medium carrying a surface transplant of *P* resulted in some delayed surface growth in the higher dilutions of the compound where there had been complete inhibition in the absence of albumin, and, moreover, growth was noted in the depth of the medium even at a drug concentration of 20 mgm. per cent.

The conditions governing the bacteriostatic activity of aminobutoxypyridine in sub-surface culture were, therefore, examined more closely. It was found that, in sub-surface culture, its inhibitory effect against *H37Rv*, *SB* and *P* in the synthetic basal medium was considerably reduced by the addition of albumin, substantial granular growth, or diffuse growth in the case of *P*, being evident at the highest drug concentration tested (10 mgm. per cent). This antagonistic effect is not specific to albumin, since a similar result was obtained if the latter was replaced by the non-ionic synthetic detergent 'Tween 80' (a polyoxyethylene derivative of sorbitan mono-oleate) at 0·05 per cent; this product is known for its marked stimulating and dispersing effect on the growth of *Mycobacteria*[3]. The simultaneous addition of albumin and 'Tween 80' led to total, or almost total, abolition of inhibition of the three strains over the range of drug concentration tested (10–0·1 mgm. per cent), profuse diffuse growth occurring at 10 mgm. per cent. To test the possibility that some constituent of the synthetic basal medium might be a factor, these experiments were repeated with *H37Rv* in the Proskauer–Beck medium; the bacteriostatic effect shown in the medium alone over the range of drug concentrations, 10–0·1 mgm. per cent, was totally abolished by the addition either of albumin, or of 'Tween 80', or of both. Finally, the effect of reducing the inoculum was examined; with 1/100 the usual inoculum of *H37Rv* and 1/1,000 that of *P*, the inhibition previously observed was evident in the synthetic basal medium, but definite growth was again noted in the tubes containing albumin, or albumin and 'Tween 80', and the drug at a concentration of 10 mgm. per cent.

Certain factors or combinations of factors can, therefore, antagonize to a marked degree the inhibitory effect of aminobutoxypyridine on the growth of *Mycobacteria*. This antagonism can be observed in sub-surface culture when carried out in the presence of serum albumin or of certain growth-stimulating lipids. The antagonistic effect of serum albumin was surprising in view of the fact that Feinstone[1] has stated that the tuberculostatic activity of the drug was not antagonized by up to 25 per cent of whole blood or serum. The present findings have an unfavourable bearing on the possibility of this substance proving a useful chemotherapeutic agent. It should be added that both streptomycin and licheniformin show clear inhibitory end-points under the conditions of sub-surface culture in the Dubos albumin–'Tween 80' medium described here.

Sex Reversal in *Patella coerulea* L. and *Diodora gibberula* (Lam.)

CREWE[1] has recently discussed the possible influence of helminth parasites on sex determination in limpets. Following the earlier observations of Orton[2], I have been studying the problem of sexuality in the Mediterranean limpet *Patella coerulea* L., both statistically and histologically. In contrast to the conditions in *Patella vulgata*, no larval Trematodes have been observed in several thousands of *P. coerulea* which I have examined. These parasites must therefore be at most extremely rare in the present populations of *Patella* in the Bay of Naples.

My statistical observations with *P. coerulea*, represented graphically in the appended diagram, show the sex proportions in different size-classes in the months November, January and March. The total numbers examined are given: fuller numerical details will be published elsewhere.

The data available permit the following conclusions to be drawn: (*a*) most individuals of *P. coerulea* undergo sex inversion from the male to the female phase as they grow older; (*b*) a small proportion seem to be determined as females from the beginning of sexual differentiation; (*c*) a small proportion remain as males throughout life; (*d*) sex inversion may occur in any size class; (*e*) the rate of sex inversion does not keep pace with the rate of increase; this fact is made evident by the shift in the point of

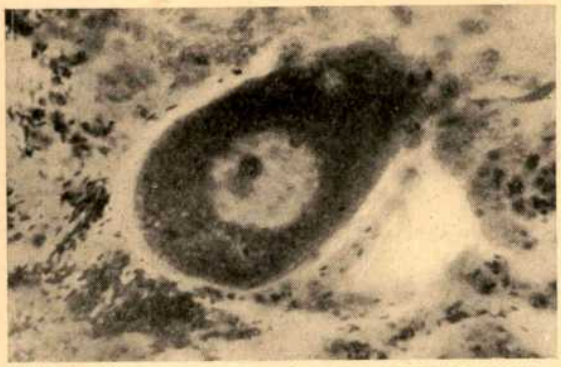

Fig. 1. YOUNG OOCYTE IN A PREDOMINANTLY MALE GONAD

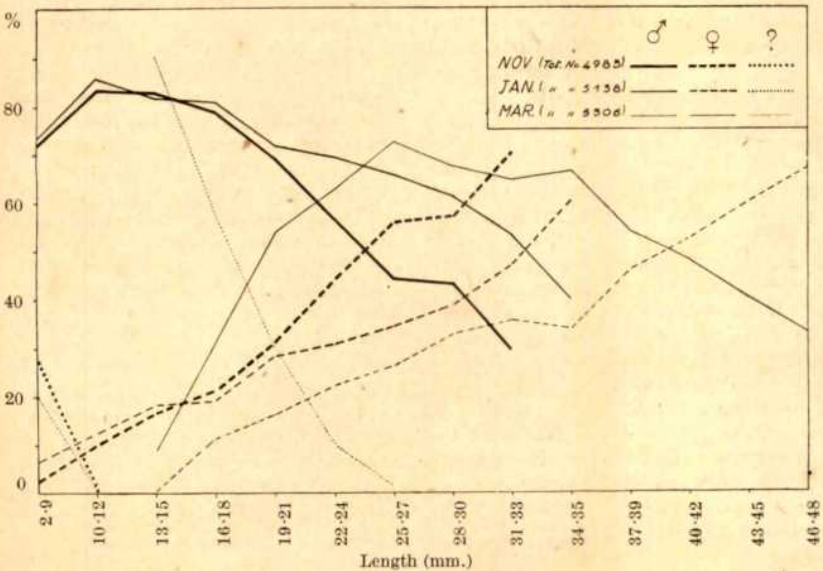

Fig. 2

intersection of the curves for males and females from lower to higher size-classes during these months.

Histological evidence is fully in support of these conclusions. Sex inversion can be observed: young oocytes can be found in gonads which are predominantly male (Fig. 1). A few young individuals show female gonads with no trace of a preceding male phase. Gonads in the state of inversion are found in individuals of various size-classes. Sex inversion generally occurs immediately after the spawning of the male products. This accounts for the different rates of sex inversion and increase in size during the breeding season. Furthermore, histological examinations show that the gonads of *P. coerulea* have no distinct male and female territories. The morphologically hermaphroditic stage is of very short duration.

Analogous conditions have also been found to obtain in another primitive prosobranch, *Diodora gibberula* (Lam.).

Sex inversion in *P. coerulea* at Naples, in the absence of trematode parasites, leads one to suppose that the presence of trematode parasites in *P. vulgata* may only accelerate the normal process of inversion.

Relation of Total Soluble Solids in the Cell Sap of *Sesamum* Species to the Degree of Susceptibility and Resistance to *Antigastra* (Lepidoptera–Pyralidæ) Attack

It has been found that *Sesamum orientale* L., which is grown widely in India as an oil-seed crop, is very susceptible to *Antigastra catalaunalis* Dup. (Pyralidæ) caterpillar attack, and also to phyllody or 'Green flower disease', believed to be caused by a virus. There also occurs in India a wild species of *Sesamum* prostrate in habit which, according to Ramanujam[1,2], is resistant to both *Antigastra* and virus attack. In order to evolve pest- and disease-resistant strains of cultivated *Sesamum*, crosses were attempted between *S. orientale* (I.P.6) and *S. prostratum*, which resulted in the synthesis of a hybrid species *S. indicatum*. This synthetic species was reported to be intermediate in respect of parental characters, but showed, according to the author, greater resistance to the pest and to phyllody than the cultivated species.

Under laboratory conditions, an attempt was made to discover the degree of food preference of *Antigastra* for the three different species of *Sesamum*; it was found that under identical conditions they prefer *S. orientale* and *S. indicatum*. The laboratory observations thus support the field observations.

While it is almost certain that the resistance of certain varieties or species is dependent upon the absence of some chemical groups attractive to insects which infest them, others are resistant because of the existence of substances that might have a repellent action. Yamasaki and Arikado[3] determined the Brix value of varieties of sugar-cane susceptible, and of those resistant, to the attack of white louse *Ceratovacuna (oregma) lanigera* Z., and concluded that there probably exists a minimum critical point in the Brix value for attracting the white louse, which according to them was 4·5 (Ref. Brix). In the absence of any definite external physical characteristic in the plants affecting such resistance or susceptibility, an attempt was made to determine the relationship, if any, of the total soluble solids present in the three different species of *Sesamum* with their susceptibility or resistance to *Antigastra* attack, and the following results were obtained:

Species of plants	Brix value of leaf (Abbe extract refractometer)		Resistant or susceptible
	Range	Mean	
Sesamum orientale (Cultivated species)	1·344–1·346	1·345	Susceptible
Sesamum indicatum (Hybrid species)	1·338–1·340	1·339	Susceptible
Sesamum prostratum (Wild species)	1·351–1·352	1·351	Resistant

The above results indicate to a certain extent that when the Brix readings of the cell-sap is between 1·338 and 1·346, the species concerned are likely to remain susceptible; and when the readings were 1·351 or above, the species were less susceptible or resistant. It is thus likely that the presence of excess soluble solids in the cell-sap of the leaves of the wild species of *Sesamum* renders it less liable to *Antigastra* attack. Further work on these lines is in progress.

Occurrence of *Botrytis Fabæ* Sardiña in England

THE Chocolate Spot disease of broad and field beans is well known and widespread throughout Great Britain, and causes considerable loss of crop when there is high humidity and much rain at the time of flowering. The cause of the disease, in the eastern counties at least, was shown by A. R. Wilson[1], in 1937, to be the common fungus *Botrytis cinerea* Fr. He proved, however, that similar symptoms could be brought about by other *Botrytis* species, such as *B. Tulipæ* Lind.

We have now shown that in the south-west of England, Chocolate Spot is caused mainly by *Botrytis Fabæ* Sardiña. This fungus was described from Spain by Sardiña[2] in 1929, and has been recorded also from Morocco, Cyprus, Egypt and China. It is readily distinguished from *B. cinerea* by its larger spores and smaller sclerotia. Our identification has been confirmed by Dr. P. H. Gregory.

Speciation in Cichlid Fishes of East African Lakes

PROF. C. KOSSWIG has suggested[1] that factors which may contribute to the high evolutionary response of Cichlid fishes to the environments of the Great African Lakes are selective mating and specialized breeding habits, including monogamy at least until one brood becomes independent. A beginning has been made in the study of a group of closely related species in Lake Nyasa, the *Tilapia* of the *T. squamipinnis* group[2,3]. Before 1939 these had been considered as a single species. Slight differences in pharyngeal dentition had been observed in the larger fishes among a score of specimens in the British Museum (Natural History); but these, and slight variations in proportions of head and mouth, had not been thought sufficient for the recognition of more than one species. Field-work during the fishery survey of 1939 revealed that there are in Nyasa probably four closely related species, for some of which it is still convenient to use local names, Chambo, Saka, Lidole and *T. karongæ* (the local name of which I do not know). These seem to be the Nyasa representatives of the *T. galilæa* group of the genus, but all resemble each other much more closely than any species outside the Lake. Females and non-breeding males of all are silver-grey with nearly vertical black bars. In Chambo the male becomes pale blue as the testes ripen; in the other three, ripe males are black. The four species (if they are species) cannot yet be recognized at all stages, but Lidole and Chambo can be distinguished from each other at a total length of 26 cm. and more, and it is to these two that the following remarks apply.

The morphological differences between them are that Lidole has a more slender and more feebly toothed lower pharyngeal bone, usually a larger head and a larger mouth. The essential differences, that is, those that isolate them from each other, are: the breeding male of Lidole is black, that of Chambo is pale blue; the female of each shelters the young in her mouth, but only Chambo brings them into the reed-beds; Chambo ceases to shelter the young after they have reached a total length of 15 mm., Lidole continues to shelter them in her mouth up to a length of 40 mm. In addition there is evidence suggesting that Chambo inhabits a more inshore, Lidole a more offshore zone, although these zones overlap; and that the mating places are separate, that of Lidole being farther from shore than that of Chambo. Both species feed mainly on phytoplankton, and it would need a very extensive study to establish any average difference in the feeding habits. Presumably, however, Chambo has more opportunity to vary the plankton diet with periphytic Algæ or those of the bottom film, and the floating matter of the inshore water would include coarser organic debris than that of offshore water. The slight difference in dentition may be associated with these facts.

If it be assumed that the inshore habit is the more primitive, recent events show how the offshore habit may have been assumed. Since 1939, the level of Nyasa has risen, and in 1945 and 1946, when Miss R. Lowe went to Nyasaland to continue the *Tilapia* studies begun by my colleagues and myself in 1939, the reed-beds, where it was customary to trap Chambo, and near which it was customary to seine them in the breeding season, were drowned, and the native fishing season was a failure. European fishermen, however, fished in open water with special gear and, I understand, caught Lidole, and one of the other species. It may have been such a change in lake-level that first gave rise to a race of *Tilapia* that managed to do without the reed-beds as nurseries for their young, sheltered them in the maternal mouth longer in compensation, and kept to the open water and a purely planktonic diet. A fall in lake-level could provide locally the conditions favourable to the evolution of a more inshore form from a specialized lacustrine form. This may perhaps account for the presence of the other two species, repeated fluctuations resulting in an alternating direction of the evolutionary process, with the fixation of partially converging forms occupying overlapping ecological niches.

In these species, at least, it is only the female that has been found sheltering young in the mouth. The evidence points to a separation of the sexes during the period when the young are being sheltered. In the case of Chambo, males and females were caught in the shore-seines, but the only adults caught in traps among reeds were spent females, some with young. Of Lidole, from the end of January to the beginning of May the inshore methods used caught 120 (recorded) spent females, some with young, and only four males, none in breeding condition. No specimens were recorded with eggs in the mouth, and it is possible that until the fry hatch the parents may remain together near the 'nest'.

The habits of Saka and *T. karongæ* are still undescribed, but Miss Lowe has been studying these fishes in the field for eighteen months, and her results should advance our understanding of this problem.

A pair of species paralleling Lidole and Chambo was described in Lake Victoria by Graham[4,5]. Morphological and colour differences between these are more pronounced. As well as the specific colour, there is evidence of breeding isolation in that in one species the male has the genital papilla elaborated into a brightly coloured tassel at breeding time, in the other it has not; and that breeding females, or spent females with young in the mouth, are trapped in fences across creeks and inlets in the case of one species, but not the other. Graham[5] records that the offshore species "incubates the eggs in her pharynx and no doubt shelters the young", but of the inshore species, although females sheltering young in the mouth were recorded, none was found with eggs in the mouth.

There is no doubt that the detailed study of the specific characters, ethological as well as morphological, of the Cichlidæ of the African lakes offers a unique and fruitful field for the student of evolution.

Copper in Diatoms

THE communication on this subject in *Nature* of May 10, from Mr. N. I. Hendey[1], raises a number of points which require some comment.

The reported values of the concentration of copper in sea-water vary from 0 to 30 mgm./m.^{3}, and Mr. Hendey's figure of 0·007 mgm./l. (7 mgm./m.^{3}) lies within this range. Taking an approximate mean value of the copper content of diatoms given by Mr. Hendey as 100 μgm./gm. and even assuming they contain only 10 per cent dry matter, the concentration factor for copper is of the order of 1,400. The magnitude of this value in relation to the small reported figures for the concentration of copper in sea-water would suggest that copper might play an important part in the economy of diatom outbursts, if this element is a vital constituent of the diatom cell and if planktonic forms have copper contents of this order.

However, the diatoms analysed (samples 3–11) were taken from Group 1, namely, those living in frondose colonies of mucous filaments, and it appears possible that the copper was largely contained in the embedding mucus. It has been shown repeatedly here[2] that mucous films absorb large quantities of copper from sea-water, when exposed to this element either under culture conditions, or even when in proximity to raft-exposed anti-fouling compositions releasing copper.

Further, Mr. Hendey suggests that the diatom slime film which develops upon underwater surfaces may be considered as a potential reservoir of copper, and so may play an important part in preventing the settlement of other fouling organisms. A considerable amount of evidence has now been accumulated which indicates that anti-fouling action is dependent upon the rate of loss of poison from the surface; for effective action this rate should exceed a critical value[3,4]. Mr. Hendey does not present any evidence which suggests that the copper associated with the diatom slimes is capable of release; indeed, the reverse is suggested by the implication of his speculations on the form in which the copper is contained.

Studies of the fouling settlement which occurs on surfaces releasing copper certainly confirm the fact that some diatoms are relatively insensitive to this poison; but no evidence has been obtained, in the course of many thousands of assessments of anti-fouling compositions, that the slimes associated with such diatom settlements can act effectively as anti-fouling surfaces.

If a composition which is capable of maintaining an effective leaching-rate for a period is immersed in the sea, it usually acquires a covering of diatoms (due to their relative insensitivity); this settlement may persist for some time, during which period the diatoms are in contact with a surface at which the concentration of copper is far higher than that of sea-water. These conditions would therefore seem much more favourable for uptake of copper by the diatom slime; yet, in our experience, such a slime immediately gives place to more sensitive fouling organisms once the leaching-rate of the paint drops to a value which allows their settlement.

A cuprous oxide anti-fouling composition containing 10 per cent copper (that is, containing 10^5 μgm./gm.), when applied at a normal weight per unit area, has a very short anti-fouling life (of the order of 100 days) and is not easy to formulate so that the copper is being most economically used. It would therefore be surprising if a diatom slime film containing 164 μgm. copper per gm., the release of which is a matter for speculation, could be more effective than even this type of composition.

It is, of course, possible that the copper contained in the diatom slimes is bound in such a way that it could only be released when another organism came into contact with the slime. Such a condition would represent an advance of the first magnitude in the search for an effective anti-fouling surface; but we suggest that such an action should be sought in a surface considerably more stable and permanent than a diatom slime.

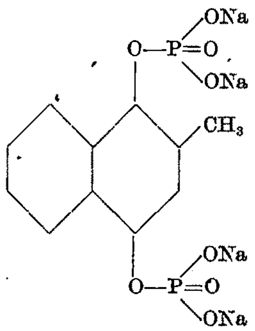
COMBINATION OF SOME EFFECTS OF X-RADIATION AND A SYNTHETIC VITAMIN K SUBSTITUTE

By Prof. J. S. MITCHELL and Mrs. I. SIMON-REUSS
Department of Radiotherapeutics, University of Cambridge

THE present work is part of an investigation to try to improve the results of treatment of neoplastic diseases by the combination of radiotherapy with suitable chemotherapeutic agents. It seems reasonable to examine ancillary chemical agents likely to modify cellular nucleic acid metabolism, since there is now considerable evidence[1] that therapeutic doses of X- and gamma-radiations inhibit the synthesis of thymonucleic acid in proliferating normal and malignant cells.

The compound so far studied in greatest detail is a water-soluble synthetic vitamin K substitute, namely, tetrasodium 2-methyl-1-4 : naphthohydroquinone diphosphate :



It is of interest that Lehmann[2] and Lehmann, Lüscher and Huber[3], using *Tubifex* eggs, showed that 2-methyl naphtho-quinone, the corresponding hydroquinone, and a number of related compounds are inhibitors of mitosis.

In the present investigation the effects of the synthetic vitamin K substitute followed by small doses of X-radiation were observed, using chick fibroblasts in tissue cultures. On the basis of these results, and in view of the recognized low toxicity of synthetic vitamin K substitute[4], preliminary clinical trials, including examination of biopsy specimens, were made in the treatment of selected patients with advanced malignant tumours, which were not likely to respond satisfactorily to conventional radiotherapy. The clinical findings will be reported elsewhere; but it must be emphasized that at the present stage no therapeutic value is claimed.

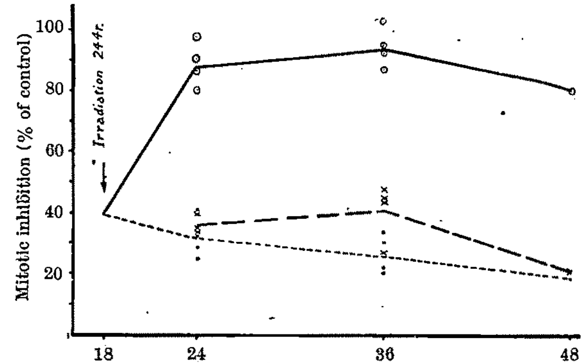


Fig. 1

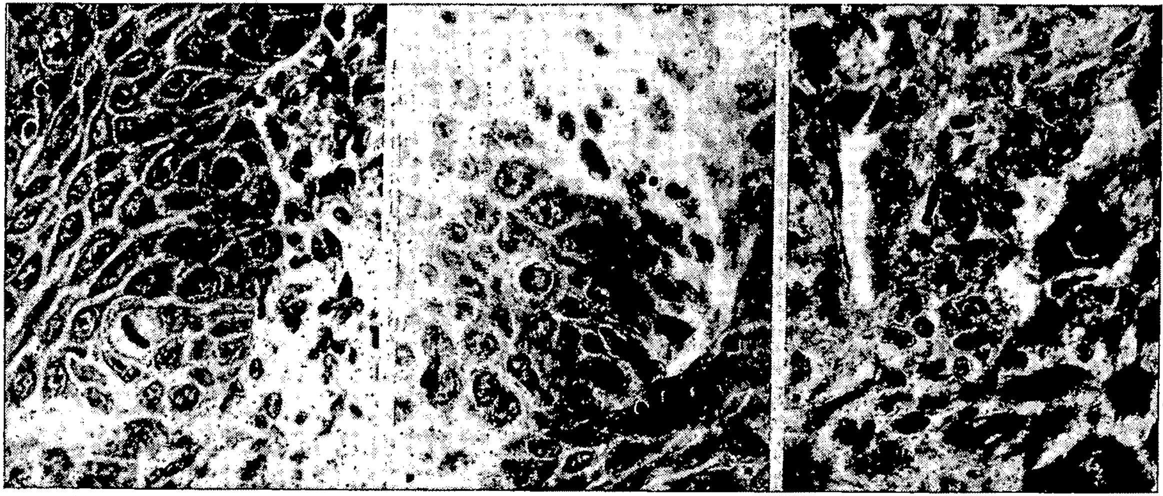
——, synthetic vitamin K substitute ($3 \times 10^{-6}\,M$) + irradiation 244 r.; – – –, irradiation only (244 r.); . . . ., synthetic vitamin K substitute only ($3 \times 10^{-6}\,M$)

The tissues used for all the culture experiments were taken from the choroid and sclerotic of a 10- to 11-day-old chick embryo. The cultures were grown by the usual hanging-drop technique in a medium of equal parts of fowl plasma and of 15 per cent embryo extract in saline. Two groups of six cultures of the third passage were selected and matched for use as experimental material and controls. The synthetic vitamin K substitute, or other compound to be tested, was added in solution to the embryo extract to give the required final molar concentration. The cultures were fixed in Susa at the times stated and stained with Heidenhain's hæmatoxylin. The total number of mitotic cells in the treated specimens were counted and compared with the number in the untreated controls.

The synthetic vitamin K substitute alone produced mitotic inhibition increasing with concentration. After application for twenty-four hours, at the



a b c

Fig. 2

following concentrations, the total mitotic counts observed expressed as a percentage of mitosis in the controls were as follows:

(a) $2 \cdot 5 \times 10^{-6}$ *M*, 82·0 ± 4·5 per cent.
(b) 3×10^{-6} *M*, 69·3 ± 2·3 per cent.
(c) 4×10^{-6} *M*, 51·6 ± 1·0 per cent.
(d) 5×10^{-6} *M*, 22·7 ± 4·9 per cent.
(e) 6×10^{-6} *M*, 23·7 ± 4·1 per cent.

For 3×10^{-6} *M* initial concentration, the mitotic count varied with the time of application, having the value after 18 hours, 61·7 ± 4·7 per cent; after 24 hours, 69·3 ± 2·3 per cent; after 36 hours, 75·2 ± 2·9 per cent; and after 48 hours, 82·5 ± 3·4 per cent. The values for 24 and 36 hours are the most reliable.

In each of the experiments showing the effects of X-radiation on the cells treated with the synthetic vitamin K substitute, four sets of cultures were chosen. To two, the compound was added to give a final concentration of 3×10^{-6} *M*; the other two were used as controls for the compound only and for the radiation only. One group treated with synthetic vitamin K substitute and one control group were irradiated after 18 hours with 244 r. of X-radiation of effective wave-length approximately 0·20 A. (H.V.L. 0·5 mm. copper) delivered in 2 minutes. Mitotic counts were made for all four groups at 24, 36 and 48 hours. The results are summarized in Fig. 1, and indicate significant potentiation of the mitotic-inhibiting effects of X-radiation and of the synthetic vitamin K substitute. For example, after 24 hours, X-radiation alone produced 64·9 ± 1·6 per cent of the number of mitoses present in the controls, and synthetic vitamin K substitute alone 69·3 ± 2·3 per cent. The observed effects of the combination produced 14·0 ± 3·8 per cent, while independent action would give 45·0 ± 1·9 per cent. A similar highly significant difference was found at 36 hours; and even at 48 hours, where the experiment is becoming difficult, a significant effect was found.

With regard to the preliminary clinical trials, the qualitative findings so far are not inconsistent with the above measurements. The low toxicity of the synthetic vitamin K substitute has been confirmed. In twenty-five patients with advanced cancer, no attributable toxic effects were observed with doses of 100 mgm. administered intramuscularly daily for times up to six weeks. One man received 500 mgm. intramuscularly daily for 42 days without any demonstrable toxic effect. X-ray therapy was commenced at least three days after the synthetic vitamin K substitute.

The histological changes found in biopsy specimens are exemplified in Fig. 2, which shows typical fields, for a case of advanced squamous cell carcinoma of the floor of the mouth: (a) in the control biopsy specimen; (b) in that taken after administration of 100 mgm. of synthetic vitamin K substitute daily for 16 days; and (c) that taken at 4 days after the end of a course of X-ray therapy in which the minimum tumour dose 3,500 r. was delivered in overall time 8 days, by which time the synthetic vitamin K substitute had been given for 44 days. In the control specimen (a) 5,000 cells were counted, and the frequency of mitosis was 3·98 ± 0·28 per cent. In (b), after synthetic vitamin K substitute alone, the frequency of mitosis was found by counting 10,000 cells to be 1·12 ± 0·11 per cent, indicating a highly significant reduction. Further, the ratio of prophases to metaphases was significantly reduced. After the irradiation, counts were impossible because all the tumour cells were grossly degenerate. At the doses used, the synthetic vitamin K substitute alone produced many mitotic abnormalities, including clumping and stickiness of chromosomes and anaphase bridges.

Summarizing: a synthetic vitamin K substitute, tetrasodium 2 - methyl - 1 : 4 naphthohydroquinone diphosphate, produces mitotic inhibition in chick fibroblast cultures and in some human carcinomata. In the tissue cultures, significant potentiation of the effects of X-radiation and of the synthetic vitamin K substitute in inhibiting mitosis is found under suitable conditions. Preliminary clinical trials confirm the low toxicity of the synthetic vitamin K substitute. At the present stage of investigation, no therapeutic value is claimed.

PLASTIC OPTICAL SYSTEMS FOR TELEVISION

IN the type of television receiver most commonly used at the present time, the picture is produced on the fluorescent screen of the cathode ray tube, which is viewed directly or through a suitably placed plane mirror. The 9- or 12-in. cathode ray tubes normally used give pictures of about 8 in. by 6 in. in dimensions, while a somewhat larger picture is obtained with a 15-in. tube. This, however, probably represents the practical limit of picture size in this type of domestic receiver, since larger cathode ray tubes are unwieldy and expensive items. At the same time, it is desirable that the television receiver of the future should produce a picture of about twice the above size in linear dimensions, and preferably on a flat screen. With this object in view, developments had begun several years ago of a reproducing system using a small cathode ray tube with a fluorescent screen only two or three inches in diameter, on which a bright clear image is produced, the light from this image being then projected through a suitable optical system to give an enlarged picture on a flat screen. While considerable progress has been made in cathode ray tube design, the picture brightness obtainable on the tube is insufficient to give satisfactory results when using an optical system of the conventional type. For this reason the Schmidt optical system, which was originally designed for use in astronomical telescopes, has been applied to the projection of television pictures. The great advantage of this system is that it has a large light-gathering property, and so enables the utmost use to be made of the picture-brightness on the cathode ray tube.

As mounted for use in a television receiver, a deep concave mirror of large aperture is placed opposite the end of the cathode ray tube and projects the light forward past the tube towards the viewing screen. In order to correct for the spherical aberration introduced by a mirror of such large aperture, a corrector plate is introduced into the projection system. This plate has a non-spherical surface of complex shape and, in the Schmidt system, is mounted at the centre of curvature of the mirror. To produce such an optical system in glass is, however, a slow and expensive matter, since the aspherical surfaces of the corrector plate require long and patient hand-work by a highly skilled craftsman. Although many attempts have been made to produce such plates by means of machines designed to work the surfaces automatically, this has so far not been considered to be an economic proposition for the mass-production of domestic television receivers. These limitations have now been largely removed by recent developments in the formation and use of transparent plastic materials, and particularly by the introduction of a surface-finishing process by means of which plastic components of high optical quality can be produced on a large manufacturing scale.

A description of these developments with demonstrations of their application to television reception was given in a lecture on May 29 before the Television Society by Dr. D. Starkie, of the Plastics Division of Imperial Chemical Industries, Ltd. Two plastic materials are available in bulk supply in Great Britain. They are poly-methyl-methacrylate and poly-styrene, and are supplied in optically pure forms as 'Transpex 1' and 'Transpex 2' respectively, with transmission values for visible light corresponding approximately to those of crown and flint glass. These materials are sensibly unaffected by continuous exposure to sunlight, and, although they have a softening temperature of about 120° C., by taking great care to avoid any strain in the material during fabrication, finished components show no measurable change in form when used under the most severe operating conditions. The production of the components takes place in two stages. First, a 'preform' is cast as accurately as possible by some known method. Then a thin skin of the same material is built up on the surface of this preform inside an optically worked glass mould, until the surface of the component makes optical contact at all points with the mould. A transparent mould material is necessary since part of the reproduction process is polymerization by light; but, in addition, glass is the hardest material available in bulk supply and all risk of scratching during use must be avoided. The aspheric moulds are first machined as accurately as possible and then finished by a skilled optical worker by hand. The preparation of such moulds is still a long and expensive matter; and it is only justified by the fact that, once a mould is made, a considerable number of accurate plastic reproductions can be made from it. The time required to make an optical component by the surface-finishing process is quite long, although the actual handling time by the operators is short. It has been decided, therefore, that in order to keep production costs low enough to allow the optical systems to be used in domestic television receivers, a large number of moulds should be used and these should travel through the various stages of the process on a mechanical conveyor. A factory to be operated along these lines is being prepared, and it is hoped to start manufacture at the end of this year.

Dr. Starkie demonstrated two prototype Schmidt television projection systems for home receivers, using cathode ray tubes of $2\frac{1}{2}$ or $3\frac{1}{2}$ in. diameter, respectively. The picture size given by both systems is 16 in. × 13 in., the chromatic aberration is small, and the resolution is claimed to be far better than is required for the present B.B.C. television transmissions using 405-line scanning. Although the smaller of the two systems requires a 'throw distance' of 40 in. between the cathode ray tube and the viewing screen, it was shown how this could conveniently be incorporated in a receiver console of normal dimensions. A third Schmidt system suitable for television projection in small cinemas was also demonstrated: this contained a mirror of 18 in. diameter and gave a picture with a length of diagonal of $12\frac{1}{2}$ ft.

Although the lecture was primarily devoted to the use of plastic optical components in television reception, it was pointed out that since the new surface-finishing process allows complicated aspherical optical components to be made at a reasonable cost, it is likely to have an important effect in the general field of applied optics.

BRITISH IRON AND STEEL RESEARCH ASSOCIATION

OPENING OF SKETTY HALL LABORATORIES

SKETTY HALL, Swansea, was opened on July 3 as the South Wales Laboratories of the British Iron and Steel Research Association. Mr. G. H. Latham, president of the British Iron and Steel Research Association, received a gold key from the Mayor of Swansea, and guests proceeded to an inspection of the Laboratories.

At present the bulk of the Association's work is of necessity carried out through the facilities of its members and at the universities and other appropriate institutions. Nevertheless, considerable progress has been made in establishing a number of laboratories specially adapted for co-operative research. For example, at the University of Sheffield a team is studying problems connected with rolling practice, and plans are well advanced for the establishment of a metal flow station in Sheffield for practical investigations into all forms of metal working and plastic deformation problems; in London, a physics laboratory is shortly to be opened; there is a corrosion-testing laboratory at Birmingham, and marine biological work is carried out at Millport, Scotland.

At Sketty Hall, a mansion with an interesting local history extending over a century and a half, made available to the Association by the Swansea Corporation, comprehensive facilities have been provided.

The chemistry section has a spacious laboratory, and the metallurgical section has two laboratories, all on the ground-floor. The metallurgical rooms are respectively equipped with various heat-treatment furnaces and physical testing apparatus. On the same floor is the small workshop with the instrument mechanic's room adjacent, and the galvanizing and tinning shop, which will be sited in what seems to have formerly been a brew house. This shop is already furnished with ventilation for drawing off the brewery fumes, though the arrangements may have to be improved to dispose of the rather less appetizing by-products of the shop's new functions.

The first floor provides two laboratories for the physics section, and two for the electro-chemical section, in which there is equipment for plating. The physics section, being engaged on investigating the geometrical and physical characteristics of metal surfaces, is equipped with a sensitive profilometer of the latest pattern, and will have electron diffraction equipment later in the year. The profilometer is a Talysurf machine, on which a stylus traverses the specimen and records the roughness of the surface on a graph, with an adjustable magnification of 400–100,000 times. It also provides a rapid 'average' reading for the surface of the specimen.

It was found necessary to instal this equipment on a thoroughly stable base, and one of the physics laboratories has had to be provided with a ferro-concrete floor, on which the Talysurf and the electron diffraction apparatus are to be housed.

The second floor has comprehensive metallographic facilities, with separate preparation laboratory and photographic room.

There are many problems which can be attempted within the scope of these facilities. Besides studies of metal surfaces, there are studies of the thickness and distribution of coatings of various sorts, and of the porosity of coatings. The Swansea team has already done considerable work on these subjects, which promises to be of ultimate benefit both to users and makers of the products concerned. Other problems which it will be the function of Sketty Hall to investigate include such questions as the influence of the composition of the steel and its method of manufacture on surface coatings; the physical and chemical characteristics of metal surfaces; the adhesion of coatings; electroplating; de-wetting and many others.

Other work carried out at Sketty Hall involves field tests on melting furnaces and works in the South Wales area, concerned with such matters as fuel distribution and gas flow in gas producers (in conjunction with the British Coal Utilization Research Association); the effect of deterioration of ingot mould surfaces on the surface of the ingot and subsequent products; the determination of the moisture content of hot raw producer gas, and the assessment of the value of instrumentation of open-hearth furnaces. For these purposes a quick immersion thermocouple is being used, and apparatus has been developed for rapid determination of the moisture in producer gases. These, together with other equipment, are being mounted in a mobile laboratory.

The organisation of the Swansea laboratories is the task of the Coatings Committee of the Mechanical Working Division of the Association, one of the six divisions under which the Association's work is organised. This Committee was formed about fourteen months ago, and the first meeting was held on May 15, 1946, under the chairmanship of Capt. H. Leighton-Davies, who remains the chairman to-day. The terms of reference of this Committee, for which the greater portion of the work of Sketty Hall is to be carried out, are: "To consider and investigate all matters concerning metallic and other inorganic coatings on steel and all processes for surface preparation associated therewith". This is, of course, a very wide field, involving close collaboration between research workers in allied fields (such as the co-operation that exists between the British Non-Ferrous Metals Research Association and the British Iron and Steel Research Association) and between research workers and users.

The formation of the Coatings Committee was not by any means the origin of co-operative research in South Wales, which was started in 1932 by the South Wales Siemens Steel Association and the Welsh Sheet and Plate Manufacturers' Associations. A team of investigators then worked at University College, Swansea, under Mr. D. Luther Phillips.

Early in 1946 arrangements were made for the British Iron and Steel Research Association to take over the work of the two research Committees, and it is the new function of Sketty Hall to house the continuation and expansion of their investigations. Mr. Luther Phillips is now in sole charge of the laboratories, and the closeness of Sketty Hall to University College, Swansea, ensures continuity.

A lunch at Swansea Civic Centre followed the opening ceremony. Besides Mr. G. H. Latham and the Mayor of Swansea, Mr. Percy Morris, M.P., Sir Lewis Jones (vice-president of University College, Swansea), Capt. H. Leighton-Davies and Sir Charles Goodeve (director of the Association) spoke.

Mr. Latham emphasized the part co-operative research has to play in ensuring that we have the steel output as necessary to Great Britain's economic recovery as the output of coal. Throughout all the speeches there was much emphasis on the healthy degree of co-operation which exists between the Research Association, the University College, the municipality and local industry. In inviting industrialists to make the freest possible use of Sketty Hall's facilities, Sir Charles Goodeve stressed the fact that science alone is not a panacea for our ills, but must be allied to strong and continuous effort. Tribute was paid to the very considerable amount of work that had gone into the conversion of Sketty Hall. Its rapid progress must be laid to the credit of Mr. Luther Phillips and his staff, and to the efforts of the contractors.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, July 21

Anglo-Austrian Society (at Gas Industries House, 1 Grosvenor Place, London, S.W.1), at 8 p.m.—Prof. H. Mark (Institute of Polymer Research, Brooklyn): "Austrian Science, Past and Future".

Saturday, July 26

Amateur Entomologists' Society (at Buckingham Gate Central School, Wilfred Street, London, S.W.1), at 2 p.m.—Annual Exhibition.*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Physics (honours graduate, to teach physics to B.Sc. standard) at the Municipal Technical College and School of Art—The Director of Education, Education Office, Library Street, Blackburn (July 26).

Junior Technician for physiological research—The Secretary, The University, Aberdeen (July 26).

Lecturer in Zoology and Chemistry—The Registrar, Merchant Venturers' Technical College, Bristol (July 26).

Lecturer in Mechanical Engineering—The Principal, Dudley and Staffordshire Technical College, Dudley (July 26).

Lecturer in Applied Mechanics at the Royal Naval College, Greenwich—The Director, Education Department, Admiralty, London, S.W.1 (July 26).

Chief Lecturer in Mechanical Engineering—The Registrar, Leicester College of Technology and Commerce, Leicester (July 26).

Lecturer in Geography at the Liverpool College of Commerce—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (July 26).

Lecturer in Chemistry and Mathematics at the Oxford School of Technology—The Chief Education Officer, City Education Office, 77 George Street, Oxford (July 26).

Works Chemist—The Secretary, Rochester, Chatham and Gillingham Gas Company, 95 High Street, Rochester (July 29).

EXPERIMENTAL OFFICER (male) for work in dairy husbandry and farm management—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (July 31).

PRINCIPAL RESEARCH OFFICER, RESEARCH OFFICERS (8), SENIOR TECHNICAL OFFICERS (2), and a TECHNICAL OFFICER, for work concerned with a study of jet propulsion and subsonic, transonic and supersonic flight for military and civil use, at the Long-range Weapons Establishment at Salisbury, near Adelaide—The Deputy High Commissioner, Australia House, Strand, London, W.C.2 (July 31).

LECTURER and an ASSISTANT IN MATHEMATICS—The Secretary, The University, Aberdeen (August 5).

READER IN SURVEYING at King's College, Newcastle-upon-Tyne—The Registrar, The University, 46 North Bailey, Durham (August 8).

PERMANENT LECTURER to take charge of teaching of SCIENCE in senior school courses, a TEACHER OF SCIENCE at the secondary technical school (Merton Road branch), and LECTURERS (2) IN MATHEMATICS in senior full-time and part-time courses—The Principal, Brixton School of Building, Ferndale Road, London, S.W.4 (August 9).

RESEARCH OFFICER, Heat Section, Division of Physics, Sydney—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1170 (August 11).

LECTURER IN PSYCHOLOGY—The Registrar, The University, Manchester 13 (August 11).

UNIVERSITY LECTURER IN THEORETICAL CHEMISTRY, and a UNIVERSITY DEMONSTRATOR IN ORGANIC CHEMISTRY—Dr. F. B. Kipping, Secretary of the Appointments Committee, Faculty of Physics and Chemistry, Chemical Laboratory, Pembroke Street, Cambridge (August 15).

JUNIOR ASSISTANT PHYSICIST to the Radiotherapy Department—The Clerk to the Governors, St. Thomas's Hospital, Westminster Bridge, London, S.E.1 (August 15).

LECTURER (Grade IIa), and ASSISTANT LECTURERS (2, Grade III), IN THE DEPARTMENT OF BIOCHEMISTRY—The Secretary, University College London, Gower Street, London, W.C.1 (August 15).

SENIOR LECTURER IN GEOLOGY—The Registrar, University College, Singleton Park, Swansea (August 16).

CHAIR OF COLOUR CHEMISTRY AND DYEING—The Registrar, The University, Leeds 2 (August 18).

BIOLOGICAL RESEARCH ASSISTANT—The Superintendent and Secretary, Jessop Hospital for Women, Sheffield 3 (August 23).

READERSHIP IN PATHOLOGY at St. Thomas's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (August 28).

ASSISTANT KEEPERSHIPS IN (*a*) GEOLOGY, (*b*) BOTANY, (*c*) ART—The Director, Museum and Art Gallery, New Walk, Leicester (August 30).

PROFESSOR OF ELECTRICAL ENGINEERING (general), a PROFESSOR OF ELECTRICAL ENGINEERING (electrical power generation, transmission, and utilization), a PROFESSOR OF MECHANICAL ENGINEERING and a PROFESSOR OF CIVIL AND HYDRAULIC ENGINEERING, in the Indian Institute of Science, Bangalore—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (August 31).

JUNIOR POSTS IN THE DEPARTMENT OF STATISTICS or one of the Biological Departments, for teaching and research in the use of statistical and other mathematical procedures in the Biological Sciences—The Secretary, University College London, Gower Street, London, W.C.1 (August 31).

PROFESSOR OF CIVIL ENGINEERING CONSTRUCTIONS AND FOUNDATIONS, a PROFESSOR OF STEEL BRIDGES AND METALLIC STRUCTURES, a PROFESSOR OF ARCHITECTURAL CONSTRUCTION, a PROFESSOR OF STRENGTH OF MATERIAL, a PROFESSOR OF DESIGN OF ELECTRICAL MACHINERY, and a PROFESSOR OF EXECUTION DESIGN, in the Faculty of Engineering, Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (August 31).

LECTURER IN THE DEPARTMENT OF PHYSIOLOGY—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (September 1).

LECTURESHIP IN PALESTINIAN ARCHÆOLOGY—The Director, Institute of Archæology, University of London, Regent's Park, London, N.W.1 (September 1).

CHAIR OF PHYSIOLOGY at St. Thomas's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 2).

PROFESSOR OF SOCIAL AND PREVENTIVE MEDICINE, and a LECTURER IN PSYCHOLOGY—The Secretary, Queen's University, Belfast (September 6).

RECTOR OF THE CANTERBURY UNIVERSITY COLLEGE, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 15).

LECTURER IN INORGANIC AND PHYSICAL CHEMISTRY, and a LECTURER IN APPLIED CHEMISTRY—The Secretary, The University, Edinburgh (September 15).

PRINCIPAL, SOUTH AFRICAN NATIVE COLLEGE, Fort Hare, C.P., South Africa—The Principal of the College, or The Secretary, Universities Bureau of the British Empire, 24 Gordon Square, London, W.C.1 (South Africa, September 30).

SENIOR ASSISTANT—The Secretary, Appointments Committee, The Observatory, Armagh, Northern Ireland (October 1).

CHEMISTS (2), a CHEMICAL ENGINEER, BOTANISTS (2), a PLANT PATHOLOGIST, an ADVISORY OFFICER (pathologist), and an ADVISORY OFFICER (Soils Chemist), in the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, South Kensington, London, S.W.7.

PLANT PHYSIOLOGIST IN THE BOTANY DEPARTMENT—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8.

LECTURER IN ELECTRICAL ENGINEERING—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

ASSISTANT LECTURER AND DEMONSTRATOR IN THE PHYSIOLOGY DEPARTMENT—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

RESEARCH ASSISTANT IN THE DEPARTMENT OF CHEMICAL PATHOLOGY—The Chemical Pathologist, Westminster Hospital Medical School, 17 Horseferry Road, London, S.W.1.

LECTURER to take CIVIL AND MECHANICAL ENGINEERING SUBJECTS, with special reference to the Theory and Design of Structures, at the Cardiff Technical College—The Director of Education, City Hall, Cardiff.

LECTURER IN CHEMISTRY (with particular reference to physical chemistry)—The Principal, Medway Technical College, Gillingham, Kent.

LABORATORY ASSISTANT IN THE DEPARTMENT OF BIOCHEMISTRY—The Establishment Officer, University College London, Gower Street, London, W.C.1.

LABORATORY TECHNICIAN IN THE DEPARTMENT OF ZOOLOGY—The Secretary, University Science Laboratories, Durham.

LECTURER IN MATHEMATICS—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

DEMONSTRATORS (2) IN PHARMACY—The Registrar, University College, Nottingham.

ASSISTANT LECTURER IN LOGIC AND SCIENTIFIC METHOD—The Secretary, London School of Economics and Political Science, Houghton Street, London, W.C.2.

EDUCATIONAL PSYCHOLOGIST—The Chief Education Officer, Shire Hall, Cambridge.

THE SOCIAL SCIENCES AS A FACTOR IN INTERNATIONAL COLLABORATION

IT is a feature of the reviews of the year's work of the Rockefeller Foundation which its president, Mr. Raymond B. Fosdick, is accustomed to give, that they provide not merely a picture of the activities of the Foundation but also of the fundamental needs and problems in the intellectual as well as the physical life of mankind that the Foundation is trying to serve or to solve. In this way these reviews have come to possess a value for assessing the importance or significance of trends in the scientific world or in the activities of other organisations that is almost unique. The review for 1946 admirably illustrates this characteristic, and will be read with interest and profit by those interested in the new World Health Organisation established under the United Nations, the development of the social sciences, the fostering of understanding between the West and the East, or the promotion of that full intercourse of minds in every field of intellectual effort upon which the advancement of knowledge depends.

The Foundation has made concrete contributions in all these fields during the year. Grants to the social sciences totalled 2,633,677 dollars, covering four primary fields. Those in the first field, of international relations, went to bodies conducting research and education designed to strengthen the foundations for a more enlightened public opinion and more consistent public policies; they included one to the Food Research Institute, Stanford University, for the preparation of a history and appraisal of the world's experience in handling food and agriculture during the War, and two grants dealing with the question of the social implications of atomic power. In the second field, of economic research, grants were made to the Economics Research Section, University of Manchester, the Department of Applied Economics, University of Cambridge, and the Institute of Economics, University of Oslo. In the third field, four or five modest grants were made in support of studies in the functioning of American political democracy; while in the fourth field, of research and training agencies, 216,000 dollars were voted to the Social Science Research Council, the Canadian Social Science Research Council and Johns Hopkins University. A final grant of 250,000 dollars was made for the erection of the giant 200-inch telescope on Mount Palomar in California, making a total appropriation of 6,250,000 dollars to the California Institute of Technology for this purpose.

Announcement of these grants, however, is not the most impressive feature of Dr. Fosdick's review. It is when he goes on to ask what is the justification for this huge expenditure of money and effort, and to discuss the implications of the unconquerable exploring urge within the mind of man, that Dr. Fosdick touches on the fundamental issues. He does not deny that knowledge is dangerous, but he insists that the answer does not lie in trying to curb science or to fix boundaries beyond which intellectual adventure should not be allowed to go. The search for truth, he maintains, is, as it always has been, the noblest expression of the human spirit. Man's hunger for knowledge about himself, his environment and the forces by which he is surrounded, gives human life its meaning and purpose, and clothes it with final dignity. Civilization is not being betrayed by science: the danger lies in the failure to use science wisely.

This is the point of view which has prompted the Foundation to extend the support of the social sciences already noted. The lack of balance in research is admitted. Our knowledge of human behaviour and social relations is inadequate to give us the guidance we need through the rapid changes in our physical environment. The fundamental issue of our time is whether we can develop understanding and wisdom reliable enough to serve as a chart in working out the problems of human relations, or whether our lopsided progress will be allowed to develop to a point that capsizes our civilization in a catastrophe of immeasurable proportions.

What is needed, Dr. Fosdick continues, is a broader basis of research, a more vigorous backing of objective and competent efforts to define and analyse the intricacies of human relationships. We need to know what our social organisation is, how it operates, and how it will react to alterations and changes. In our interdependent society, issues are no longer simple, individual and local; they are complex, social and world-wide. Our real need is a mastery not of Nature but of man's social nature, and of the social consequences of physical and mechanical advances which are shaping our lives to undesired ends.

An encouraging feature in the situation is the increasing recognition of the importance of the social services, even although it has yet to secure the necessary expansion of effort in this field. Like the Clapham Report, Dr. Fosdick insists on the importance here of disciplined minds and the high integrity of objective scholarship. We must secure a continuous flow of first-class talent into these fields, for the standard of research will depend on the quality of the men just as much as it does in the physical sciences.

But while the Rockefeller Foundation concerns itself both with the endowment of research in specific fields and with the training of men, it is equally concerned with the conditions which make research fruitful, and the appropriations of the Foundation have been distributed internationally with the purpose of breaking down the isolation and intellectual stagnation which war brings. The flow of ideas across boundary lines, the free exchange of periodicals and books, and the cross-fertilization of minds working in the same scientific and cultural fields—the interruption of these are among the tragic losses of war the magnitude of which Dr. Fosdick rightly points out is impossible to assess. We shall never know the advances which might have occurred had there been contact during these years between the biologists, the biochemists, the physiologists and mathematicians of the United States and a dozen Western European countries, or if, for example, the energy and knowledge and unselfish co-operation which were devoted to making the atomic bomb had been applied instead to some of the great basic problems of biology and medicine.

It is implicit in Dr. Fosdick's review that war interrupts and hinders the advance of science; but the review shows unmistakably the determined effort the Foundation has made to assist the resumption of research and to link up the intellectual life of Europe with that of the rest of the world. Europe is still perhaps the world's greatest power-house in terms of brains and skill, of human values and creative talent, and the grants made by the Foundation in its chief divisions—natural sciences, medical sciences, humanities, social sciences—have been designed to provide equipment and support for universities, libraries and research centres as well as to create methods of communication by which such institutions can re-establish contacts with each other and with the rest of the world, as, for example, through a series of international conferences in such fields as chemical genetics, protein structure, enzyme chemistry and cellular physiology. Into this international stream it is important to bring Russian scientific thought, and a grant has been made for that specific purpose.

Dr. Fosdick does not claim that the Foundation has been able to do more than make a very modest contribution towards the initiation of efforts to solve the great problems which Europe's intellectual needs present, and he looks very plainly to the United Nations Educational, Scientific and Cultural Organisation for the major contribution in this field. If, as Prof. L. A. Du Bridge urged in an address to the Society of the Sigma Xi and since published in *The American Scientist*, the fundamental problem is to turn the great resources of science into the paths of peace, that problem can never be solved by one country alone. Prof. Du Bridge puts the freedom of science first in his programme, and insists that no measures for extending the training of scientific workers, educating the public as to what science could contribute to the welfare of mankind, and expanding and improving the resources for research in pure and applied science, must impair that freedom; and he recognizes that fundamentally the problem of science is not national but international. Science must be applied to the specific problems of human adjustment, and the conduct of affairs be guided by the scientific method of critical examination and evaluation of actual experience rather than by raw emotion, vested authority, or prejudice, not just in one nation, but in the relations of nations with one another.

No durable world order can be established until we approach this condition, and the real hope of the Educational, Scientific and Cultural Organisation of the United Nations lies in the contribution which its work can make to that end. Therein, perhaps, is the importance of the project for the creation of the International Institute of the Hylean Amazon, now to be examined by an international scientific commission. The field work of the three scientific investigators who are going to Brazil for this purpose will constitute the first international co-operative scientific effort in a gigantic forest area, the natural resources of which, from the scientific point of view, are virtually unexplored. The proposed Institute will study the botanical, zoological, chemical, geological, meteorological, anthropological and medical facets of this area and also its potentialities as a habitat of non-indigenous peoples.

It is no disparagement of the three major projects already approved by the Executive Board of the United Nations Educational, Scientific and Cultural Organisation for 1947—an educational reconstruction programme on behalf of devastated member countries ; a campaign for the spread of fundamental education ; and the promotion of international understanding, primarily in education—to suggest that such projects as this for the Amazon basin are of outstanding importance. The demonstration in such ways of the practical contribution of science to human welfare is one of the most valuable factors in the task of educating public opinion in all countries as to the place and value of the scientific approach. It may be that the way towards world order is through the slow growth of a series of social experiments on the lines of the Tennessee Valley Authority, with its demonstration of the possibilities and effectiveness of co-operation between the expert and the ordinary citizen. But while such experiments lie outside the field of the United Nations Educational, Scientific and Cultural Organisation, that Organisation can still do much to prepare the way and to promote the conditions of success. Nor should it be forgotten that the pursuit of science for its cultural value remains worthy of man's best effort.

Science, indeed, has a contribution to make to the cultural and moral equipment of mankind as important as that of any body of literature or art. Indeed, from the point of view of world order, the contribution of science is unique. Alone of man's major intellectual interests, science has no frontiers and no national varieties ; like peace, science is one and indivisible. Dr. Fosdick's review in the annual report of the Rockefeller Foundation demonstrates admirably how science can help, unobtrusively but persistently, in the task, not merely of repairing the havoc of war and ameliorating man's material life, but also of promoting a wider understanding of human affairs, human values and motives. Upon these factors may some day be firmly based a true science of social living and a world order in which man's cultural and spiritual needs no less than his material wants find ample satisfaction.

KINETICS OF BACTERIAL GROWTH

The Chemical Kinetics of the Bacterial Cell

By Prof. C. N. Hinshelwood. Pp. x + 284. (Oxford : Clarendon Press ; London : Oxford University Press, 1946.) 20s. net.

THIS book is not a treatise or a monograph. It is an essay, in which the author has expanded the main ideas which led to his own and his group's important work on the kinetics of bacterial growth. Actually this essay has one major theme on which attention is constantly focused : the cause and mechanism of 'adaptive' variation of enzymatic properties in the bacterial cell. Indeed, the importance of the problem could scarcely be overstated, since a clear understanding of these phenomena, as they occur in bacterial cells, might throw light on basic problems in other fields of biology, such as genetics and embryology.

A large body of interesting experimental results, mostly from the author's own laboratory, has been condensed in the book, the greater part of which is concerned with the acquirement and loss of the capacity to resist drug action, or with using new sources of carbon and nitrogen. This will no doubt prove very useful for future reference.

The main object of the theoretical discussions is to see whether, and to what extent, these experimental data may be interpreted in terms of rather simple models of linked enzymatic reactions, that is, whether various types of change of properties may be considered as resulting from an 'automatic response' to a new environment. Practically all the discussions and mathematical treatment of the data are based upon one fundamental assumption, which is that each individual metabolic reaction may be represented by an equation of the type :

enzyme + substrate = more enzyme + products.

Now, the exact meaning of this equation is not altogether clear, at least at first sight, and to realize all the implications of such an assumption requires, and merits, a good deal of thought. Assuming that all the enzymes of a cell are autosynthetic structures seems to be a very bold step indeed. The fact that bacteria do grow, generally, when supplied with the necessary foodstuffs does not seem to be quite enough to justify it. It might be regretted that such an essential point should not be discussed at length, and that no *direct* experimental evidence in favour of it should be presented. (Although, in the reviewer's belief, some such evidence seems to exist, at least in a limited number of cases[1].)

However, once this postulate is accepted, interesting conclusions follow, and it is shown that the behaviour of bacterial populations submitted to new or adverse conditions can be understood as resulting from automatic adjustments of the 'enzyme balance' within each cell. The experimental data leave little doubt that this view must be essentially correct in many cases. In others, however, the evidence is far less convincing. For example, it is shown, on theoretical grounds, that prolonged 'adaptation' may conceivably lead to an *irreversible* stabilization of the new condition. This is a highly important point, as it raises the question whether such changes would be reflected in the bacterial 'genome' the existence of which seems more and more certain. Experimental proof of this point, unfortunately, appears rather doubtful, since the results might be explained just as well (sometimes much better) through the action of selection on spontaneously arising mutants.

True, the occurrence of spontaneous mutations and the importance of selection as factors of bacterial variability are discussed at some length, the general conclusion being that it seems more 'profitable' and less 'arbitrary' to consider most changes as resulting primarily from adaptive reactions, rather than from spontaneous mutations. This type of discussion is not very convincing, however. It might be argued that the 'autosynthetic enzyme' hypothesis also appears somewhat arbitrary, and that the mutation hypothesis has actually proved highly profitable in a number of important recent contributions (such as Lwoff and Audureau's work on *Moraxella*[2], Luria and Delbruck's[3], and Demerec and Fano's[4] papers on spontaneous mutations to phage resistance, Demerec's[5] work on penicillin-resistant mutants), which are not discussed.

An important chapter deals with the subject of cell division. Interesting data and interpretations are presented there, which tend to emphasize the relative independence of 'growth mechanisms' and 'division mechanism'. It is shown that, in some cases at least, each may be subject to very specific influences. This distinction undoubtedly is of great theoretical and practical importance, although it is too often overlooked.

The book ends with 'concluding observations' of a far-reaching generality, on the essential characteristics of living matter, and the possibility of understanding its origin and evolution in terms of physical forces and relations. The view is optimistic, although prudent, and it is pointed out that even the dualism of the mental and physical world may in time appear as a functional relation, the nature of which would not be very much more difficult to grasp than the relation between wave and particle, energy and matter.

BRITISH FOREST TREES

Our Forests

By W. H. Rowe. Pp. 173+34 plates. (London: Faber and Faber, Ltd., 1947.) 12*s*. 6*d*. net.

THIS is the second book covering the general subject of British forestry for the non-technical reader published since the end of the War ("Forests and Forestry", by W. L. Taylor, the recently appointed director-general of forestry, being the other), and during the same period, Edlin's book on "British Woodland Trees" has also appeared. This is a very healthy sign of an increasing interest in the woodlands of Great Britain and their place in both rural and national economy. All three books are well illustrated, and Mr. Rowe has made an excellent choice of subjects. The frontispiece, taken in a New Forest roadside plantation well known to foresters, provides an ample refutation of the charge that a coniferous crop need be an eyesore, while Figs. 5 and 6 of neglected larch woods show how one may become so; the dark thicket stage shown in Figs. 21 and 22 is after all a relatively short one. It may be claimed that the bad beech of Fig. 7 has a certain attractiveness of its own, but does it surpass that of the good beech of Fig. 8 alongside? Several of the photographs reveal what excellent growth is obtainable in Britain with a number of kinds of timber tree.

The author, already known from the useful Penguin on "Trees and Shrubs", sees forestry from the private owner's point of view, but evenly distributes the blame for the past neglect of so many of our three million acres of private woodland between both the owners and the State; he would seem to favour State control over them, but by an authority separate from the Forestry Commission responsible for the State forests—an arrangement found in some Continental countries.

There are various general statements scattered through the book that need amplification or qualification. Thus we are told that ploughing complicates rather than aids planting without giving any material advantage to the trees (p. 80), that pruning increases the volume of timber (p. 94), that the pine beetle breeds in the tops of old trees (p. 104), that the alder gives the best charcoal (p. 158)—this is only true if one wants charcoal for fuses—and that European larch and Japanese larch can be mixed with satisfactory results. There is an injunction we should not care to have to carry out in dealing with honey fungus attacks, namely, digging up all the rhizomorphs, and we cannot endorse the statement that beech does not coppice well and is on the other hand very suitable for natural regeneration in Britain. There is, too, the surprising inclusion of lime among the list of materials derived from wood (p. 158). We admit to having to refer to a dictionary to find out the meaning of the word "myrobellan" hedging (p. 82), and "coda" (p. 168).

Two chapters are devoted to notes on the individual kinds of trees. It is always difficult to know what to include and what to omit in such notes; but those given in these chapters, supplemented by those for timber uses given on p. 159, will be found useful by the people for whom the book is intended, though they are sometimes incomplete to the extent even of being misleading. One might perhaps have expected to find lodgepole pine mentioned, as it is to be seen at high elevations in many plantations in Britain, and a somewhat fuller account of sitka spruce in view of its now extensive use and the remarkable rates of growth recorded under favourable conditions. The difficulty of raising silver fir as a crop should have been mentioned.

It may be said in conclusion that it is an easy book to read and should certainly fulfil the author's avowed aim of being useful and interesting to the non-expert and general reader.

H. G. CHAMPION

ADVANCED ORGANIC CHEMISTRY

A Text-Book of Organic Chemistry

By Dr. Julius Schmidt and Dr. H. Gordon Rule. Revised and edited by Dr. Neil Campbell. Fifth edition, revised and extended. Pp. xi+939. (London and Edinburgh: Gurney and Jackson, 1947.) 32*s*. net.

THE appearance of a revised edition of this well-known work only four years after the last one calls for no comment in view of the momentous events of those years, both in the world of chemistry and elsewhere; it is indeed a tribute to the zeal of Dr. Campbell that he has not been content 'to allow chemical grass to grow unnoticed'. The printers and publishers are also to be congratulated on having completed a considerable task at a time of very great difficulty, in a manner that is a credit to all concerned.

One could wish, however, that British printers could emulate those in the United States in the neatness with which structural formulæ are reproduced. A glance at the varied and elongated benzene rings, some with double bonds and some without, apparently indiscriminately, and with substituents printed in the same way as hetero-atoms, when compared with the neat regular hexagons of some modern American books, is distressing; it is only fair to point out that this untidiness is found not only in this book, but also in all British publications with which the reviewer has come into contact. The reason is doubtless that it is not easy to print regular rings except from special blocks, the expense of which would be considerable; the fact remains, however, that the American books are little, if any, more expensive, but possibly they have a larger circulation.

The general plan of the work remains as before, and it is suitable for the advanced student and research worker rather than the novice. The first hundred pages consist of a general section treating such topics as structure, isomerism, tautomerism, physical properties and nomenclature, all essential to the proper understanding of organic chemistry, but written for the most part in such a way as to be unsuitable for the beginner: a notable section describes the basic features of chromatography.

The following three parts deal about equally with aliphatic, carbocyclic and heterocyclic compounds in a systematic manner. This arrangement and its subdivisions will be well known, as there should be no one teaching or studying organic chemistry who is not familiar with the previous editions.

It is inevitable in a book of this kind that in order to cover the field in a reasonable space much of the matter should be compressed and simplified; it is perhaps a pity that in some instances such great brevity has been considered necessary, but to compensate for this, innumerable references are given which should make it very easy for any particular topic to be studied further.

The pages to which one naturally turns at present are those dealing with such substances as penicillin, paludrine, D.D.T., etc., the discovery and investigation of which have been among the few good things of the last bleak years: all such new compounds seem to be included with an adequate account of their history and properties. It is true the preparation of paludrine and the evidence for the structure of penicillin are not given, but it is probable, when the long delays in printing are considered, that neither had been published at the time the manuscript was prepared; no doubt they will be included in the next edition. Some few pages are devoted to nucleic acids.

Errors in the text are few and seem to be minor misprints; the index, of vital importance in a book of this sort, would appear to be adequate.

CARBOHYDRATE METABOLISM

Carbohydrate Metabolism

Correlation of Physiological, Biochemical and Clinical Aspects. By Prof. Samuel Soskin and Dr. Rachmiel Levine. Pp. viii+315. (Chicago: University of Chicago Press; London: Cambridge University Press, 1946.)

THIS interesting and instructive work on carbohydrate metabolism by Dr. Soskin and Dr. Levine, who have themselves contributed much of great value to the subject, is divided into five sections.

The first section deals briefly, but very clearly and adequately, with the many enzymic mechanisms involved in the chemical transformations which take place when carbohydrates break down in the living cell. The section concludes with chapters on the mode of liberation and transfer of the energy derived from carbohydrate metabolism and on the manner in which this energy is utilized for muscular contraction. The main part played by adenosine triphosphate in the reactions of the cell is emphasized, and the significance of the work of Engelhardt and of Szent-Györgyi, on the importance, for muscular contraction, of the proteins myosin and actin, is pointed out.

The second section presents considerations concerning the nature and occurrence in the tissues of substances important in carbohydrate metabolism, and discusses the origin of blood sugar and the use of the diabetic organism for the experimental study of gluconeogenesis. The next section contains a critical survey of the classical criteria of diabetes, introducing the reader to the investigations of Minkowsky, and later workers, on the dextrose–nitrogen ratio, and deals with the subject of ketosis, showing how modern views of fatty acid breakdown supplant the older theories of ketogenesis and antiketogenesis. The complicated question of respiratory quotient is discussed, and this is followed by chapters on gluconeogenesis from protein and fat.

The fourth section presents the main course of the appetizing menu provided by Dr. Soskin and Dr. Levine. This portion of the book deals with the role of the endocrine glands in carbohydrate metabolism. The mechanism of action of insulin is fully discussed, and it is evident, as the authors say, "that while we are perhaps closer to the solution of insulin action than we are to the action of any other hormone, the problem is far from solved". The influence of the pancreas, the adrenal cortex, the thyroid and the anterior pituitary glands in the control of carbohydrate metabolism is described in some detail.

The final section has to do with what the authors term the integration of physiological and clinical aspects of carbohydrate breakdown. Dextrose tolerance curves in the normal and diabetic organisms are discussed and the effects of the various endocrine secretions in blood sugar regulation are outlined. This is followed by an account of the clinical disturbances, in the endocrine control of the blood sugar, that accompany disease or dysfunction of the glands or of the liver. The book ends with a note showing how present lines of investigation indicate that it is becoming impossible to subdivide the subject of metabolism into separate compartments, there being so many substances of simple chemical structure which are common to many phases of cell metabolism. The limitations and potentialities of present lines of work in advancing both endocrinology and pharmacology are pointed out.

The book is a clear and able exposition of many of the facts of, and the modern views bearing on, carbohydrate metabolism. It is a pity, perhaps, that a little more was not said on the subject of the association between certain forms of mental disturbances and carbohydrate breakdown—a subject of great interest to the psychiatrist who has witnessed the effects of insulin shock treatment in schizophrenia, or the effects of carbohydrate in improving prolonged narcosis treatment both in psychoses and neuroses. The importance, too, of glucose in securing, under physiological conditions, the synthesis of acetylcholine in the central nervous system might have been commented upon.

The work has most useful schematic representations which help to clarify the subject-matter, and more than a thousand references. It is an excellent book which should be read by all interested in recent work on the metabolism of carbohydrates in the animal body.

J. H. QUASTEL

THE MISSING FACTOR IN SCIENCE*

By Prof. HERBERT DINGLE

Professor of the History and Philosophy of Science, University College, London

IT is now more than three hundred years since Galileo originated the process in philosophy which, in its maturer form, we now call science. This "method of philosophating", to use Salusbury's quaint seventeenth-century phrase, calls for careful scrutiny—not, at this time of day, to decide whether it has value or not, but to determine precisely what its value, its significance and its potential danger might be. One aspect of science, I think, is in general imperfectly appreciated, namely, its essentially progressive character. The motive-power behind all philosophy is the need or the desire to understand the meaning of experience, and especially those parts of experience which touch us most deeply. Accordingly, the pre-scientific philosophers took all experience for their province and aimed at producing at once a scheme of things which could comprehend the whole.

The philosophy which has come to be known as science made a radically different approach to the problem. The problem itself was the same—the interpretation of all experience; but the first requirement was certainty, not completeness. There was one department of experience in which certainty could be attained—namely, our experience of the movements of bodies. We could study these and obtain results which could be checked and confirmed. True, such knowledge was not soul-shaking, but it carried conviction with it, and on it as a basis one might mount to further knowledge, until at last it might be that the whole secret of experience would be read—not now plausibly conjectured but guaranteed as certain by its attainment through verified experience itself. And so the early men of science stopped discoursing of the origin and destiny of man and began to roll balls down slopes, to swing pendulums, and to weigh the water which dripped from a bottle. They had not necessarily a different standard of ultimate relative values from the other philosophers, but they had a different conception of how the goal could be reached.

Several consequences follow from this, of which I will mention only one—namely, that the history of science is inseparable from science itself. Science is essentially a process, stretching through time, in contrast with the instantaneous or eternal character of traditional philosophy. Scientific workers may forget the ground on which their knowledge rests; but they are not then educated men. To the true man of science they are as the artificer to the artist, the sleep-walker to the explorer, the instinctive cry to the pregnant phrase. Such a one may achieve much of value, but he is also a potential danger. At the moment he happens to be a profoundly disquieting menace to our civilization.

Let us look at this question of science and civilization, for although I believe that in its profoundest sense science is a personal philosophy and that its character as a progressive discovery of the inter-connectedness of our experience is a plant of which its present social function is a transient flower, there is no doubt that the relation of science to communal life is the question of the moment. The progress of three hundred years is indeed amazing, and its effect on our social life overwhelming. Materially, our civilization is shaped and directed by science. The possibilities in the control of life loom over us like thunderclouds, big with menace or mercy, we know not which. And scientific psychology celebrates its birth most noticeably by the generation of an army of third-rate novelists whose influence is all the more to be reckoned with because it is incalculable. In such a situation it is clear that there is no task more compellingly urgent for the sociologist than that of determining precisely what is this process which we call science; and when we contemplate the ideas of the essential nature of science which are most prevalent and operative to-day we find a situation fit to make the angels weep.

I do not say, of course, that one cannot find penetrating and worthy attacks on the problem in present-day writings, but one has to search for them. The ideas that command wide assent are not merely false but obviously false; they have only to be confronted with the most outstanding characteristics of science as it both apparently and actually is, to be recognized as such by the most elementary intelligence. I must limit myself to two examples.

"The cleavage between the scientific and the extra-scientific domain of experience," wrote the late Sir Arthur Eddington[1], "is, I believe, not a cleavage between the concrete and the transcendental, but between the metrical and the non-metrical." Thus arose, or perhaps was greatly intensified, the belief that the scope of science is limited to the measurable and its activities to the discussion of measurements. This was broadcast from pulpit and loud-speaker; it has found an echo in philosopher, in divine, in essayist, in novelist and in street-corner orator. No idea of the nature of science is more widely accepted to-day.

And yet, if one adopts the elementary, barn-door method of comparing the dictum with science itself, what does he find? As likely as not the most typical piece of scientific achievement that will occur to him will be the outstanding generalization of the nineteenth century, the theory of evolution, and if so, he can scarcely fail to notice that that theory has nothing whatever to do with measurement. It is concerned with qualitative changes alone, and is indubitably a scientific theory which changed the course of the world's thought without introducing or depending on a single measurement. And yet intelligent and learned men say and believe that science is concerned only with measurement!

My second example can be introduced by a passage which forms the starting-point of Prof. J. D. Bernal's recent consideration of the social function of science[2]. After contrasting two definitions of science—one, that it is "a pursuit of pure knowledge for its own sake", and the other, that it is "the means of obtaining practical mastery over nature through understanding it"—Bernal decides in favour of the second, and on it bases the whole of his subsequent argument. Now here again the consequences of adopting such a view are far-reaching and momentous. As everyone knows, political theories based on such a view of science are extremely active and powerful at the present time. Clearly it is worth while looking again at science as it actually is, to see if it conforms to this definition.

There are several ways in which we can do this. Perhaps the most direct and unquestionable is to look at the universal criterion by which papers submitted for publication to recognized scientific societies and journals are tested, for the essence of authentic science is contained in the publications of such agencies. And if we ask whether mastery over Nature forms any part of that criterion we see immediately that it does not. Or let us look at any examination paper for a degree in science. We shall find a large variety of questions, but none concerned with mastery over Nature. Or let us ask the "New English Dictionary", which purports to give all the commonly accepted meanings of words, what the word 'science' means. It will give us thirteen answers, but obtaining mastery over Nature is not one of them. Or let us look at the achievements for which the well-recognized prizes and medals are awarded to men of science. Again we shall look in vain for examples of mastery over Nature. After which it is perhaps superfluous to recall that the most terribly obvious characteristic of science to-day is that it is a means by which Nature seems about to master us.

---

* Substance of the inaugural lecture delivered at University College, London, on June 6.

Now this phenomenon, of which I have given two examples, is extremely disquieting. That it has not aroused adequate alarm is, I believe, simply because it appears incredible and so its possibility is not entertained; but there is no doubt about it. Let us face it squarely and see what it means. It is not a matter of a few ignorant demagogues giving hasty generalizations which fail to cover minor details. Here are two distinguished thinkers, undoubtedly men of exceptional ability and deservedly held in high esteem in the scientific world, making statements of the greatest import which even an intelligent child can see to be directly contradicted by facts—not obscure facts but the outstanding, the obvious facts. And the statements are believed; and not only believed but made the basis of thought and action. The situation would be comic in some circumstances; but, standing as we do at a point in the world's history where nothing but a stark realization of facts in their naked simplicity can avail to save us, the mask of comedy drops from it and it appears tragical. What is to be done about it?

It is not my task, or within my competence, to propose an immediate course of action for the salvation of the human race, but it is my task to inquire how it has come about that a generation so amazingly proficient in the practice of science can be so amazingly impotent in the understanding of it, and the thesis I wish to propose is that the state of unselfconscious automatism in which science finds itself to-day is due to the lack throughout its history of a critical school, working within the scientific movement itself and performing the function, or at least one of the functions, which criticism has performed for literature from the earliest times. Greek tragedy, as well as its Euripides, its Sophocles, had its Aristotle; Roman poetry could show, with Horace and Virgil, a Quintilian, a Longinus. Throughout the ages there has gone, hand-in-hand with the work of the creators, the interpretation of the critics—Dante, Jonson, Dryden, Lessing, Wordsworth, Coleridge, Sainte-Beuve, Arnold—and the result, in spite of abuses, notwithstanding mutual recriminations and misunderstandings, has been that the stream of literature, without losing its momentum, has been directed, so that its power, which otherwise would have largely wasted itself in aimless dissipation, has been able to produce a cumulative effect.

We look in vain for the corresponding names in science. True, there occasionally arises a Mach, a Duhem, a Pearson, but they are conspicuous by their scarcity, and few heed them. The great bulk of the critics of science have not been within the scientific movement, and their aim has been in the main not so much to understand as to discredit it. The one-sidedness, the blindness, the coldness of science have been preached *ad nauseam*, and the men of science themselves, if they have looked up from their work to notice the attacks at all, have been contented with a half-hearted defence, satisfied for the most part to be obviously doing something without caring to define even to themselves what their activity means. Science has thus progressed like a ship with an all-powerful engine and no compass or rudder or steersman, measuring its progress in knots and not in terms of approximation to a desired haven, while its only 'guidance' has come from airmen overhead who, knowing nothing of its nature and potentialities, shriek their conviction that it will never reach the stratosphere.

It is not difficult to see how this lamentable difference between science and literature has arisen. Literature in its naked simplicity has no intrinsic standards, and was thus led by necessity to become self-critical. But science *has* intrinsic standards. A scientific statement must, directly or indirectly, express experience and be subject to the test of experience. If the expression is indirect, the connexion must be rational. These requirements have been satisfied by men of science with a consistency and purity of practice that is not even approximately equalled in any other large-scale human endeavour; that is why science has made such astonishing progress in so short a time. Over its terrain of rocks and quicksands science walks as sure-footed as a mule—and as sapient. It has no need of standards of judgment and so has produced no critical school, but by this omission it has lost the other and greater benefit which such a school can give—namely, that of surveying, describing and interpreting the movement itself. That is why it can combine such brilliancy of achievement with such obscurity of understanding.

A critical effort within science can perform at least two necessary functions. It can direct the movement itself, so that blind alleys are avoided and the path of progress illuminated; and, still more important for the world as a whole, it can make science self-conscious and aware of the significance of what it is doing in relation to other human activities. This cannot be done effectively from outside; it is only within the world of science that the necessary knowledge exists. It is no small calamity, therefore, that that world, with some honourable exceptions, is so indifferent to the attempt to understand and interpret its own activities. It makes no provision for recognizing and encouraging such an endeavour. Let me throw one sidelight on this, to reveal the general position. Sir Arthur Eddington spent the later years of his life in developing a theory of the fundamentals of physics which has met with little response because of the difficulty of understanding what it is all about. Nevertheless, it contains such an impressive wealth of agreement between theory and observation that it is impossible any longer to doubt that the theory contains something of the most profound significance. Both the intrinsic value of the theory and the illegitimacy of at least part of Eddington's exposition of it appear unquestionable.

Now let us imagine a thinker whose powers of penetration enable him to pierce through the obscurities of Eddington's diction to the underlying truth;

to realize also, with equal clearness, the more orthodox points of view of Einstein, Bohr, Dirac and others; to see wherein the outlooks differ and how they can be reconciled; and to re-express the work of all in terms compellingly obvious, so that the contribution of Eddington can be assessed at its true value and physicists everywhere united on a common front in an immensely strengthened position for apprehending and solving the problems that remain. There can be no doubt, I think, that such a man would render to physical science the greatest benefit possible to it at the present time; yet the world of physical science has no provision for acknowledging such a benefit. For slightly inferior intellects there are Copley Medals, Orders of Merit, Nobel Prizes and the like, but for him, nothing. Like Bunyan's Interpreter, he makes pilgrimage possible, and is heard of no more. He has added nothing to knowledge; he has not discovered a single new fact of observation or revealed a single relation between measured quantities or introduced a single new concept into the subject. Everything of that kind has been done by others before him; he has simply brought to light what they have done. I submit that a condition in which clear-sighted understanding is esteemed so lightly in comparison with blind achievement is not one which ought to be regarded without misgiving.

If we try to look into the immediate future the misgiving grows. We are about to experience a great increase of scientific activity. Existing universities are to be enlarged and new ones created, and we may look forward to a rapidly growing army of young workers, becoming more and more specialized as time goes on. Competition for entry to the Royal Society will be greatly intensified, and since entry is to be gained by doing things and not by knowing what one is doing, those who pause to reflect on the meaning of their work will fall behind in the race and remain outside. At the present time the Royal Society contains, chiefly among its older Fellows, some—though far too few—who have been able and willing to supplement their specialized work by giving attention to its wider implications. Through their labours and those of their forerunners the Society has supported research into the nature and history of science in various ways, for which we cannot be too thankful. But such efforts will almost inevitably decrease, and while I do not believe that the race of historians or philosophers of science will die out, the conditions of the time will be such that they will be automatically segregated. Instead of a vigorous critical school growing up within and promoting the welfare of science, we are likely to have an artificially stunted one growing up without and conflicting with it. Such a prospect bodes little good either for science or for the community as a whole.

What are the omens on the other and brighter side? Apart from the sporadic and incalculable influence of exceptional individuals, I know of only one. I said just now that our hypothetical interpreter of modern physics could receive no recognition of his service. I was wrong. If he cared to fulfil certain other conditions well within his scope, he could earn an M.Sc. degree of the University of London in the history and philosophy of science. That may seem something of an anti-climax, and if that aspect of it should tend to direct someone towards a rectification of the situation I would not wish to temper the feeling, but it is not the aspect I want to present now. The Department of History and Philosophy of Science at University College was founded in 1923. During the sixteen years prior to its suspension at the outbreak of war, 173 students, all graduates in science, took its courses, and 84 M.Sc., 18 Ph.D., and 2 D.Sc. degrees were awarded. In the first and second year since revival, 10 and 37 students, respectively, have been enrolled. From the first the courses were planned on admirable lines, and the foundations of a uniquely valuable Department have been laid. The staff, originally comprising one part-time teacher, has grown to four full-time and one part-time teachers, with assistance from other teachers of the University who have special knowledge of the history of their own science. The University, fully aware of the need for such a Department, has given it high priority in the forthcoming expansion. It needs now but the devoted and efficient service of its members to realize at least some of the high hopes that went to its establishment.

The fact that, by the award of higher degrees within the Faculty of Science, a great University recognizes the attainment, by those trained in the practice of science, of some understanding of what they have been practising has, I think, an importance out of all proportion to the present magnitude of the effort. However inadequate it may be, its influence is genuine. It begins to create within the scientific world an atmosphere in which true science, become self-conscious, can flourish and spurious science decay. As the community is called upon to consider how it is to adjust itself to a world in which the influence of science grows ever greater, it infuses into society a leaven of men and women who are not deceived by the momentary appearance of a movement which, after taking two thousand years to prepare itself, has been gathering momentum for the last three hundred years. The example of London may in time be followed by other universities until gradually the critical spirit becomes an integral part of science everywhere, and the mad rush along the primrose way to the everlasting bonfire is changed to an ordered movement towards a preconceived and deliberately chosen goal. Provided that the effort has not come too late, it may well prove in the end to have started the process which will convert science from a mysterious menace to a comprehended blessing. Such, at any rate, is its potentiality; it remains to make it actual.

THE SPARK DISCHARGE

A DISCUSSION on "The Spark Discharge" was held at a meeting of the Physical Society in the Physics Department, Imperial College of Science and Technology, London, on April 23. The opening paper was presented by Prof. L. B. Loeb, of the Physics Department, University of California, Berkeley. Other invited speakers were Prof. J. M. Meek and Dr. T. E. Allibone.

In a survey of certain aspects of the mechanism of development of spark discharges, Prof. Loeb made particular reference to the distinctions between the Townsend theory of the spark and the streamer theory of the spark, as proposed by Loeb and Meek. The Townsend theory is now considered to apply only to the breakdown of short gaps in gases at low gas pressures, whereas the streamer theory applies to the breakdown of gaps of the order of 1 cm. or more at about atmospheric and higher pressures.

According to the Townsend theory, the breakdown of a gap occurs when $\gamma e^{\alpha d} \doteqdot 1$, where α is the number of pairs of electrons and positive ions created per centimetre in the direction of the electric field by a single electron, γ is the chance that a positive ion striking the cathode will liberate a secondary electron, and d is the gap-length. This expression enables the breakdown voltage of a gap to be determined from the known measured values of α and γ as functions of voltage gradient and gas pressure. As in individual cases the values of $e^{\alpha d}$ and γ fluctuate considerably about their mean measured values, variations in the breakdown voltage may be expected to occur. Prof. Loeb showed that the resulting relation between the applied voltage and the probability of a spark is in agreement with experimental observations of the time-lags to breakdown, and also establishes the basis for the correct evaluation of the threshold sparking voltage. Further, an expression can be deduced to relate the total observed time-lag with the formative and the statistical time-lags.

The streamer theory involves the same quantity $e^{\alpha d}$ in conjunction with a new parameter γ^1, analogous to the Townsend γ, but depending on photon production in the head of an electron avalanche, and the photon absorption in the high-field region surrounding the avalanche head. Here again an expression can be deduced for the observed time-lag of spark development in relation to the statistical and formative time-lags, and Prof. Loeb stressed the need for further experimental measurements of these quantities, particularly in order to determine the transition between the Townsend and the streamer mechanism.

The Townsend mechanism depends on the numbers of ions in the gap and is in agreement with Paschen's law, which states that the voltage required to cause breakdown of a uniform gap is a function of the product of gap-length and gas pressure. Meek's criterion for a spark, as based on the streamer mechanism, depends on the ion concentration in an individual electron avalanche, and predicts small deviations from Paschen's law. This anticipated failure of Paschen's law has been confirmed by recent measurements of the breakdown of uniform fields at high voltages, for wide ranges of gap-length and gas pressure, and Prof. Loeb showed that the experimental results accord in principle with those expected from Meek's theoretical calculations.

The streamer process develops across the gap to form an ionized path or spark channel through which the external circuit discharges. The breakdown of the gap is then complete, and the voltage between the electrodes falls to a considerably reduced value corresponding to the voltage drop along the spark channel. Prof. Meek described some of the results obtained by Mr. J. B. Higham and himself in investigations of the voltage gradients and current densities in spark channels for gaps up to 100 cm. in length in air and other gases. The various parameters are recorded either oscillographically or by photographic methods. In one of the records shown, for a spark in air carrying 100 amp., the voltage gradient at a time 1 microsec. after breakdown is 120 volts per cm., and at 50 microsec. is 25 volts per cm. These values of voltage gradient are considerably greater than those for continuous arcs carrying the same current. Measurements of the spark diameter show that the channel expands during its early stages at a speed of the order of 10^5 cm. per sec., in accordance with the results obtained by Flowers. The current density in the channel is initially of the order of 10^5 amp. per cm.^{2}, but it decreases rapidly and, for a 400-amp. spark in air, is about 2×10^4 amp. per cm.^{2} at a time of 1·3 microsec. after breakdown. Some records have been obtained for sparks in which the growth of the channel is restricted by a surrounding glass tube. Other records were described for sparks in liquids; in one oscillogram shown, for a 250-amp. spark in water, the voltage gradient measured at a time 1 microsec. after breakdown was 1,200 volts per cm.

Prof. Meek stated that in the measurements of current density the values given are determined on the assumption that the current is evenly distributed over the cross-sectional area of the spark. It is probable, however, that there are radial variations in the current density, and that the ion density and the current flow may be slightly higher near the centre of the spark than near the circumference. A further feature of spark channels is that emission of light persists for much longer times in certain parts of the channel than in others, so that the channel appears to break up into a series of discrete small regions of luminosity, in the manner similar to that of the occasionally observed phenomenon of 'bead lightning'. Prof. Meek referred to investigations of this persistence of luminosity which are now being made by Craggs and Hopwood.

The investigations by Schonland and his colleagues into the mechanism of development of lightning discharges were described by Dr. Allibone. By means of photographs obtained with a rotating film camera, Schonland has shown that the first stroke of a lightning discharge in open country is preceded by a streamer process known as a 'stepped leader stroke', which develops in a series of steps from cloud to ground at a speed of about $1{\cdot}5 \times 10^7$ cm. per sec. When the leader stroke reaches ground, the main stroke travels up the pre-ionized channel which has been established between the cloud and the ground at a speed of the order of one tenth that of light. The large currents observed in lightning discharges flow during the passage of the main stroke. The second and subsequent strokes of a lightning discharge are each preceded by a 'dart leader stroke', which usually proceeds in a single flight from cloud to ground, at a speed of about 2×10^8 cm. per sec., and follows the track traced out by the first stroke. After each dart leader there is a main stroke which develops from ground to cloud.

Rotating-camera studies have also been made for long spark discharges in the laboratory by Allibone and Meek, who have shown that considerable differences exist in the mechanism of development of long spark discharges in non-uniform fields between a point and a plane according to the polarity of the discharge. In a gap between a positive point and an earthed plane, a leader stroke develops from the positive point to bridge the whole gap, and the main stroke then takes place along the path traced out by the leader stroke. For a negative point and an earthed plane, the discharge is initiated by a negative leader stroke developing from the point; but, after this leader stroke has grown for only a short distance into the gap, a positive leader stroke develops from the earthed plane and the two leader strokes proceed towards each other to meet in the mid-gap region. The breakdown is completed by the passage of the main stroke along the track pre-ionized by the leader strokes. Considerable differences are observed in the characters of the positive and negative leader strokes. The positive leader stroke develops usually in a continuous manner, though steps occur when a high series resistance is included in the circuit, and these steps become more pronounced with decreasing gas pressure. The negative leader stroke develops in a series of sharply defined steps, and is accompanied by a considerable number of mid-gap streamers.

In all three papers it was evident that, although the various modern techniques of high-speed recording have yielded a considerable amount of experimental data concerning the development of spark discharges, there are still many aspects of the problem requiring further investigation. Also, while the mechanism of spark breakdown in uniform fields can now be explained in terms of fundamental processes, the interpretation of all observed sparking phenomena, particularly in non-uniform fields, is still by no means complete.

TATA INSTITUTE OF FUNDAMENTAL RESEARCH

IN India, where the number of institutions for research is very small, it is now keenly realized that much greater attention must be paid to research, pure as well as applied, if India is to keep pace with the progressive nations of the world. A result of this new outlook and a welcome addition to such institutions is the newly established Institute for Fundamental Research, sponsored by the trustees of the Sir Dorabji Tata Trust and the Government of Bombay, with the subsequent support of the Government of India. The object is to create a centre for fundamental research, with particular reference to atomic physics and mathematics, and also to train the young scientific workers of India in these subjects.

Tatas, the biggest industrialists of India, have a long tradition of foresight and wisdom in the employment of their resources. To-day, 85 per cent of their capital is held in public trusts for benevolent projects, chief among which is the promotion of higher education and research. They were the pioneers in founding the Indian Institute of Science at Bangalore, the Tata Memorial Hospital for cancer and the Tata Institute of Social Sciences at Bombay. The Tata Institute of Fundamental Research is the newest institution which owes its existence to their enterprise and munificence.

Since 1942, the Sir Dorabji Tata Trust has supported a Cosmic Ray Research Unit headed by Prof. H. J. Bhabha, F.R.S., at the Indian Institute of Science, Bangalore. It was felt, however, that the modern demands of fundamental research in cosmic rays and nuclear physics could only be met by means of a separate institute devoted entirely to these subjects. The Cosmic Ray Research Unit of the Indian Institute of Science was moved to Bombay in 1945, and formed the nucleus around which the new project was built. As the construction of new buildings was not possible during the War, the Institute was housed in temporary premises. It was formally opened on December 19, 1945, by Sir John Colville, Governor of Bombay.

On that occasion, when inaugurating the Institute, Sir John Colville said: "India stands in urgent need of the speedy development of her resources, both agricultural and industrial. This can only be achieved with the aid of science. For modern industry and agriculture rest, to an ever-increasing extent, upon scientific foundations, and economic progress depends on continual advances in the field of fundamental research which provides the material on which the applied scientist can work." Sir John Colville further remarked that: "Applied research, designed to meet the practical needs of industry and agriculture, and carried on in the laboratories of Government research stations or by particular firms, is necessary. It is, however, increasingly recognized that research of a fundamental character, not directed towards specific practical objectives, is of vital importance, because of its fructifying and stimulating influence on applied research, which, without it, is bound to languish. Applied research, in fact, must be kept constantly refreshed by contact with the original work of the pure scientist."

During the first year of its existence it became clear that the new Institute would have to expand rapidly, and the necessary funds for this expansion were sanctioned by the Government of India through the Council of Scientific and Industrial Research. The Institute is to-day administered by an independent council on which the Government of India, the Government of Bombay and the trustees of the Sir Dorabji Tata Trust are represented. At present the Institute has chairs of theoretical physics, experimental physics, pure mathematics and astrophysics. Provision is also made for a visiting professorship so as to enable the Institute to invite distinguished men of science from abroad to work in the Institute for a year at a time. The Institute has also several readerships, and posts for research fellows and research assistants. A number of students are given liberal stipends to enable them to work under the professors of the Institute.

Since its start, the Institute has completed an experiment for measuring the intensity of the penetrating component of cosmic rays up to an altitude of 40,000 ft. In this experiment the intensity of cosmic rays penetrating 30 cm. of lead was measured for the first time up to these altitudes. Several papers on the theory of the elementary particles and on new relativistic wave equations, on mathematical and statistics topics, have been published by members of the Institute.

The Institute will encourage to the utmost the exchange of scientific ideas. Recently a group of foreign men of science visited India as delegates to the Indian Science Congress, and the opportunity was taken to invite Prof. P. M. S. Blackett, of the University of Manchester, Prof. J. Hadamard, of the Institut de France, and Prof. S. S. Chern, of the Academia Sinica, as visiting professors to the Institute to deliver courses of lectures on their subjects.

The Council of Scientific and Industrial Research has decided that the Institute shall be the centre of all large-scale research in nuclear physics in India, and has sanctioned a scheme for the setting up, at the Institute, of a high-energy accelerator, capable of producing particles of energies up to 200 MeV. A team of ten investigators is being formed for this purpose. With the establishment of the high-energy accelerator, it is intended to lay down a long-range plan of nuclear research.

It is also likely that a small atomic pile will be set up at the Institute in the near future, which will provide further facilities for research in atomic physics, and also for the production of tracer elements. The scope of the work of the Institute will then be enlarged by the addition of departments for nuclear chemistry and nuclear biology.

A further series of experiments to measure the intensity of cosmic radiation at high altitudes and at great depths is also being planned, and it is intended to undertake these experiments soon.

The Institute is at present housed in temporary premises, but suitable buildings will be provided as soon as possible. The site chosen for the permanent buildings faces the picturesque harbour of Bombay, and is about a mile away from the heart of the city. It is proposed to undertake immediately the construction of two blocks of buildings, one for theoretical work, instruction and administration, and the other for experimental work on cosmic rays. The plans of these buildings will be so designed as to allow for the construction of additional blocks for nuclear physics and for housing the high-energy accelerator and its auxiliaries. The buildings will be completely air-conditioned and fitted with the latest equipment.

With the expansion of the activities of the Institute, the sponsors of the Institute believe that it will become an important centre of research in India within the next few years.

MECHANISM OF ENZYME SPECIFICITY IN THE DOMAIN OF CARBOHYDRATES

By Dr. A. GOTTSCHALK

Walter and Eliza Hall Institute of Research in Pathology and Medicine, Melbourne

It would appear that it is the function of enzymes to reduce the energy of activation for a given reaction. How this is effected is at present unknown. There is, however, consensus of opinion that enzyme action is initiated by a union between enzyme and substrate. Bergmann[1] has advanced the theory that the enzyme protein by virtue of polar groups arranged in a pattern at its surface makes a multipoint contact with corresponding polar groups of the substrate. An intimate relationship of this kind between the interacting groups, suitably arranged in space, of enzyme and substrate may be regarded as the material basis of enzyme specificity. In most cases a single enzyme reacts with a group of substrates, though at different rates; in some cases, however, the activity of the enzyme is directed towards one substrate only. The degree of specificity of an enzyme may most properly be expressed by the decrease in the reaction velocity caused by a change in the constitution or configuration of that substrate acted upon with the highest reaction velocity (at various substrate concentrations). During the last fifteen years the effect of constitutional and configurational changes in hexoses and their glycosidic derivatives on the activity of the enzyme concerned has been extensively investigated. In view of the results of these investigations, it seems possible to derive some principles underlying enzyme specificity in the field of carbohydrates and in some instances to mark precisely the atoms or groups of the substrate which are involved in the bonding with the receiving groups of the specific enzyme protein.

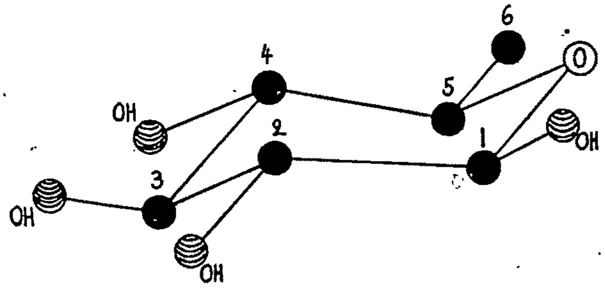

Fig. 1. BETA-GLUCOPYRANOSE (SACHSE TRANS-RING)

According to recent results[2,3] the pyranose ring of *d*-glucose is of the Sachse trans (chair-shaped) form, inter-atomic distances and angles being normal within the limits of experimental error (cf. Fig. 1). In beta-*d*-glucopyranose the carbon and oxygen atoms lie in two parallel planes 0·5 A. apart, while in beta-*d*-mannopyranose the oxygen atom attached to C_2 projects about 1½ A. from the mean plane of the ring. There is rotation about the C_5-C_6 single bond, probably restricted by an energy barrier due to the attractive and repulsive forces of neighbouring groups.

Most likely the free or substituted hexose molecules approaching the enzyme will orientate themselves with the mean plane of their ring parallel to the surface of the enzyme protein, because this will provide for the greatest development of van der Waals forces between the enzyme and substrate molecules. We assume that by hydrogen bond formation or electric dipole interaction the enzyme comes into contact with at least two groups of the hexose molecule (or hexose residue), including the one which is changed in the catalytic reaction. There can be little doubt that with glycosides as substrates the oxygen atom of the glycosidic linkage is involved in the contact with an appropriate group of the enzyme protein; indeed, the reverse reaction, the enzymatic synthesis of methyl-beta-*d*-glucoside from beta-*d*-glucopyranose and methanol is scarcely conceivable without contact being established between the enzyme protein and the two hydroxyl groups the interaction of which results in the formation of the glucosidic linkage. Moreover, evidence was recently presented[4] suggesting that the enzymatic conversion into *d*-fructofuranose-6-phosphate of the alpha- and beta-forms of *d*-glucopyranose-6-phosphate and of *d*-mannopyranose-6-phosphate is catalysed by two individual hexose-phosphate isomerases. The existence of a specific mannose-6-phosphate isomerase as distinct from the glucose-6-phosphate isomerase is to be expected; for, on the above assumptions, the conversion into a common isomeride of two stereoisomeric hexose derivatives differing in the configuration at a single asymmetric carbon atom cannot be catalysed by the same enzyme. In their association with the respective enzymes, therefore, beta-hexosides (Fig. 2) are orientated with their upper side towards the surface of the enzyme protein, whereas alpha-hexosides (Fig. 4) face the enzyme with their underneath side. The primary alcohol group, due to the restricted rotation of C_6, may be able to face the enzyme irrespective of whether the upper side or the reverse side of the glucose molecule is orientated towards the catalyst.

In a series of thorough investigations, Helferich[5], Pigman[6], Weidenhagen[7], Hudson[8] and Hofmann[9] have studied the specificity requirements of the various

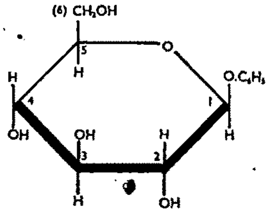

Fig. 2. PHENYL-*β*-*d*-GLUCOSIDE.

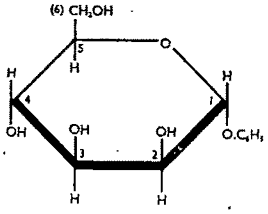

Fig. 4. PHENYL-*α*-*d*-MANNOSIDE.

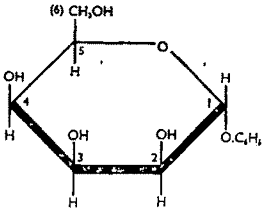

Fig. 5. PHENYL-*α*-*d*-TALOSIDE

glycosidases. It was shown that a change in the configuration at one or more ring carbon atoms or a change from the pyranose to the furanose structure renders a hydrolysable glycoside unhydrolysable by the same enzyme; for example, beta-glucosidase does not split phenyl-beta-*d*-mannoside (Fig. 3), and alpha-mannosidase is inoperative towards phenyl-alpha-*d*-taloside (Fig. 5), though these compounds differ from the specific substrates phenyl-beta-*d*-glucoside (Fig. 2) and phenyl-alpha-*d*-mannoside (Fig. 4) only in the configuration at C_2 and C_4 respectively. The effect of substitution is a different one. Thus, substitution in phenyl-beta-*d*-glucoside (Fig. 2) of the hydroxyl group at C_6 by H, F, Cl, Br or OCH_3 affects only the rate of hydrolysis by beta-glucosidase, a linear relationship obtaining between the volumes of the substituents and the logarithms of the enzyme efficiencies. Phenyl-beta-*d*-glucoside-3-methyl-ether (Fig. 6), however, is not hydrolysed by beta-glucosidase; the same holds for thiophenyl-beta-glucoside, in which compound the glucosidic linkage is effected by sulphur instead of by oxygen. Alpha-mannosidase splits phenyl-alpha-*d*-mannoside (Fig. 4) and, at much lower rates, phenyl-2-desoxy-alpha-*d*-mannoside (Fig. 7) and phenyl-alpha-*d*-lyxoside, the latter containing the alpha-*d*-manno-pyranose ring with the side chain —CH_2OH substituted by H.

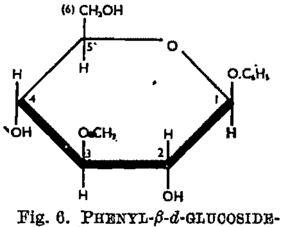

Fig. 6. PHENYL-*β*-*d*-GLUCOSIDE-3-METHYL-ETHER

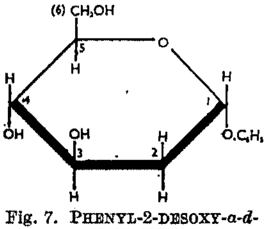

Fig. 7. PHENYL-2-DESOXY-*α*-*d*-MANNOSIDE

These results suggest that in beta-*d*-glucosides and in alpha-*d*-mannosides, besides the oxygen atom of the glycosidic linkage, only the hydroxyl groups attached to C_3 (beta-glucosides) and to C_4 (alpha-mannosides) respectively are available for contact with the enzyme protein. Concerning the bonding between the aglycon part of the glycosides and the enzyme, nothing definite can be said. It may be pointed out that in evaluating the results of substitution experiments it has to be borne in mind that the substituent group does change not only the molecular volume of the substrate but also the effective amount and the distribution of electric charge in the molecule. This may account for the observation that the 2, 4, 6-trimethyl derivative of phenyl-beta-*d*-glucoside does not react with beta-glucosidase (cf. also Pigman[9]).

The enzyme phosphoglucomutase, discovered by Cori *et al.*[10], catalyses reversibly the intramolecular shift of the phosphate group of alpha-*d*-glucopyranose-1-phosphate (Fig. 8) from C_1 to C_6, thus changing the glucosidic compound into glucose-6-phosphoric ester. As this enzyme does not act on alpha-*d*-mannose-1-phosphate or alpha-*d*-galactose-1-phosphate[11], which compounds have a reverse configuration at C_2 and C_4 respectively, we may assume that besides the glucosidic oxygen and the primary alcohol group at C_6, the —OH groups at C_2 and C_4 take a direct part in, or exert a decisive influence on, the association of the substrate with the enzyme.

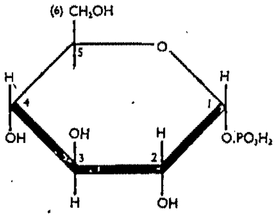

Fig. 8. *α*-*d*-GLUCOPYRANOSE-1-PHOSPHATE

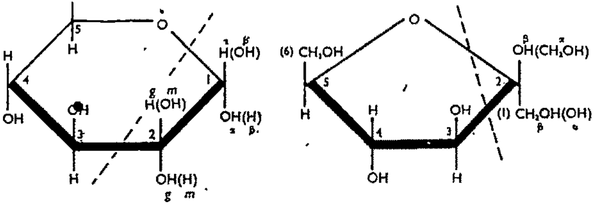
The first step in alcoholic fermentation by yeast of *d*-glucose, *d*-mannose and *d*-fructose is interaction between the mobile phosphate group of adenosine triphosphate and the primary alcohol group of the individual hexose. The common catalyst of this reaction is the enzyme hexokinase[12]. It has been established in recent years that *d*-glucose and *d*-mannose are fermentable in their alpha- and beta-pyranose forms, whereas *d*-fructose is suitable for fermentation only in its furanose form[4,13-16]. In contrast to the specificity requirements of glycosidases, hexokinase tolerates rearrangements of the atoms and groups attached to the asymmetric carbon atoms 1 and 2 of *d*-glucopyranose, and moreover the fundamental change from the pyranose to the furanose structure. The alpha- and beta-modifications of *d*-glucopyranose, *d*-mannopyranose and *d*-fructofuranose have as a common feature the same side-chain and the same configuration at C_3, C_4 and C_5 (Fig. 9 *a*, *b*). Obviously only groups of the structural pattern common to the various substrates of hexokinase can be involved in the enzyme-substrate contact; therefore, the attachment groups of the substrate may be either the —OH groups at C_3 and



(*a*) (*b*)

Fig. 9. SHOWING THE IDENTICAL CONFIGURATION AT C_3, C_4, C, AND THE IDENTICAL SIDE-CHAIN ATTACHED TO C_5 IN THE *α*- AND *β*-FORMS OF *d*-GLUCOPYRANOSE (*ag*), *d*-MANNOPYRANOSE (*am*) AND *d*-FRUCTOFURANOSE (*b*)

C_6 or those at C_4 and C_6. A decision between these alternatives seems possible on the following reasoning. Glucose oxidase (from *Aspergillus niger*) catalyses the oxidation of *d*-glucose to gluconic acid, and at a much lower rate (1/4) it also oxidizes *d*-mannose[17]. Since in this case the hydroxyl at C_1 is one of the attachment groups, it may be concluded that a change in the configuration at a carbon atom adjacent to that carrying a contacting group greatly affects the velocity of the enzymatic reaction. Further examples supporting this conclusion can be easily presented. The hexokinase reaction with *d*-mannose as substrate proceeding only at about one third of the rate of its reaction with *d*-glucose[18], the addenda to C_2 appear to be vicinal to one of the contacting groups. Hence, the —OH groups of the substrate interacting with the receiving groups of hexokinase most probably are those at C_3 and C_6.

It would thus appear that the specificity of enzymes acting on hexosides resides in some atomic groupings arranged at the surface of the enzyme protein in a pattern able to attract the hexose residue by the glycosidic oxygen and one or more hydroxyl groups in *cis*-position to this oxygen. In addition to this bonding, attraction must be assumed for one or more groups of the aglycon part of the glycoside. Thus, the substrate molecule as a whole is appropriately orientated and fixed. The activity of glycosidases is restricted to a single type of the aldo-pyranose ring, because any change in the configuration at a ring carbon atom may remove from its proper spatial position a contacting —OH group, or produce a steric hindrance by replacing a hydrogen atom with the more voluminous hydroxyl group, or result in such a redistribution of electron charge as to eliminate the possibility of bonding between the respective groups of enzyme and substrate. There are, however, enzymes acting on hexoses, for example, hexokinase, which are less sensitive to configurational changes in the substrate. The quantitative effect on the enzyme-substrate relationship of a change in configuration at an asymmetric centre depends mainly on the spatial relation of the latter to the contacting groups. A rearrangement of the hydrogen and hydroxyl group at a carbon atom adjacent to an attachment group of the substrate invariably affects seriously the rate of the enzymatic reaction. When, however, the same configurational change takes place at a carbon atom more distant from the contacting groups, the effect on the enzyme-substrate relationship is much less marked.

OBITUARIES

Prof. C. A. Kofoid

LESS than two months after the death of H. S. Jennings (see *Nature*, June 21, p. 834), America has lost another—and almost the last—of her elder workers on the Protozoa. Prof. C. A. Kofoid died—also in California—after a heart attack on May 30 at the age of eighty-one.

Charles Atwood Kofoid was born at Granville (Illinois) on October 11, 1865, and took his first degree (A.B.) at Oberlin College in 1890. He then moved to Harvard, where he graduated A.M. (1892) and Ph.D. (1894). After a short period of teaching at Michigan (1894–95), he was appointed superintendent of the Illinois Biological Experiment Station, where he remained for five years. Finally, he gravitated to the centre of his chief scientific activities—the University of California, where he became assistant professor of zoology in 1900, and professor and director of the department in 1910. He remained at this post for more than a quarter of a century, when he retired (1936) as professor emeritus.

Kofoid was a zoologist of wide interests, but devoted his great energies particularly to marine zoology, protozoology, and parasitology. He was always attracted by planktonic organisms, and while at Illinois published papers on the phytoflagellates of the Illinois River. Later, at California, he took a leading part in establishing the Marine Biological Station (now the Scripps Institution of Oceanography) at San Diego, and produced a notable series of memoirs on the dinoflagellates of that region. These were followed by exhaustive systematic monographs on the Unarmoured Dinoflagellata (with O. Swezy, 1921), the Dinophysoidæ (with T. Skogsberg, 1928), the Tintinnidæ (with A. S. Campbell, 1929), and the Heterodiniidæ (with A. M. Adamson, 1933). Earlier, he published a detailed survey of all "The Biological Stations of Europe" (1910). In the field of applied zoology, with which he was always concerned, he played an active part on various committees for studying the damage done by the shipworm (the mollusc *Teredo*: reports published in 1924 and 1927), and also that caused on land by termites (final report published in 1934); and with his pupils he paid much attention to the wonderful flagellate Protozoa living in these remarkable insects.

Towards the end of the First World War Kofoid was appointed major in the U.S. Sanitary Corps, and threw himself with enthusiasm into the study of human intestinal Protozoa. A long series of papers by himself and his collaborators was the result. But unfortunately, he approached this intricate and tricky subject without sufficient previous experience, and consequently most of his 'discoveries' and all his 'new' genera and species are now known to be misinterpretations. To the end of his life, however, he refused to give them up. In his later years he also became interested in the history of biology, and during the last decade wrote many reviews for *Isis*. He left a large library, which is housed in the University of California at Berkeley.

Kofoid will be specially remembered for his fundamental share in developing the Zoology Department of the University of California to its present distinguished status, and for his editorial work in connexion with the "University of California Publications in Zoology". These contain many important papers—including many by himself and his pupils—

which are familiar to all zoologists. His own publications are too numerous to mention in more detail, but together they constitute an integral part of the output of protozoological research in the United States during the last fifty years.

CLIFFORD DOBELL

Prof. A. W. Stewart

EMERITUS PROF. ALFRED WALTER STEWART died at his residence in Belfast on June 30, after many years of indifferent health borne with stoical courage.

The youngest son of the late Prof. William Stewart, Dean of Faculties in the University of Glasgow, he was educated at the University of Glasgow, the University of Marburg and University College, London, and had held in turn the lectureship in organic chemistry at Belfast and the lectureship in physical chemistry and radioactivity at Glasgow. In 1919 he succeeded the late Prof. Letts as professor of chemistry at Belfast. During his tenure of office in Queen's University, Stewart did much to create the school from which many of his students went to occupy important positions in industrial and academic life at home and abroad. He was a man of great learning, gifted with a fertile imagination, and laboured continually to provide a sound and fundamental training in all branches of modern chemistry. He was ever ready to give counsel to those who sought his advice, and was deeply interested in the welfare of his students.

Stewart had a special interest, born from his close association with Ramsay and Collie, in the application of physical chemistry to the elucidation of the structure and properties of organic compounds, and his work upon Tesla-luminescence spectra was especially noteworthy. He and his co-workers developed a new field of spectroscopy by employing a fresh method of excitation to reveal series of spectra each of which is characteristic of the compound which emits it, and so added a new constitutional property to those previously known.

His love of investigation and his interest in the teaching of chemistry are revealed in his many writings, notably the volumes in his series of "Recent Advances in Physical, Inorganic and Organic Chemistry", which have reached many editions. He had pleasure in recalling that he had directed attention to the elements which had identical atomic weights but which differed in chemical properties and to which he gave the name 'isobars'. Since his retirement in 1944 from the chair of chemistry in the Queen's University of Belfast, which he had occupied for twenty-five years, he had devoted himself to his literary work with increased pleasure and devotion.

To have been one of Stewart's intimate friends is a privilege and a cherished memory; of a shy and retiring disposition, he avoided all forms of ostentation, and only those who had his confidence can appreciate the kindly nature, the tender affection and the stimulating effect of an evening spent with him by his fireside. Stewart's work—both as a man of science and an author—was characterized by meticulous care and thoroughness. His interests were catholic and his learning wide. British science is poorer by his loss, and another link has been severed with the pioneers of the early years of this century.

During his years of ill-health, borne with great fortitude, he had the constant companionship of his wife and only daughter, to whom sympathy is extended in their loss.

D. N. MCARTHUR

Prof. G. E. M. Jauncey

DR. GEORGE ERIC MACDONNELL JAUNCEY, professor of physics at Washington University, St. Louis, Missouri, died on May 19 at his home in St. Louis. He was born in South Australia in 1888, and educated at the University of Adelaide; later he did graduate work under Sir William Bragg at the University of Leeds. He held instructorships in physics at Toronto, Lehigh, Missouri, and Iowa State College. In 1920 he joined the department of physics at Washington University and became professor of physics in 1930, a position which he held at the time of his death.

During the twenty years following his appointment, Jauncey carried out research on many phases of X-ray scattering, the results of which are to be found in numerous communications in the *Physical Review* and other journals. He was also deeply interested in students and the problems of teaching physics at all levels. Out of his interest in teaching undergraduates at an intermediate level resulted his widely used book "Modern Physics", which has passed through three editions.

A severe illness in 1940 resulted in a permanent impairment in his health, which made it impossible for him to continue experimental work. He then turned his attention to the history of physics. The papers which he had published were to have been followed by others in this field had he lived to work out his programme.

A. L. HUGHES

Prof. G. Matthai

WE regret to announce the death at Cambridge on June 25 of Prof. George Matthai, formerly of the Indian Educational Service and emeritus professor of zoology in the University of the Punjab at Lahore. Dr. Matthai succeeded the late Lieut.-Colonel J. Stephenson as professor of zoology at Lahore in 1919. Under Stephenson the Lahore School of Zoology had been raised to a high degree of efficiency and was *facile princeps* among the Indian Schools; Prof. Matthai worked hard to maintain this proud position, though of late years Lahore has been challenged and has had to yield pride of place to Lucknow. Prof. Matthai would under normal conditions have retired in 1942, but as a war measure his term of office was extended until 1945.

Prof. Matthai was a recognized authority on corals, and as Mackinnon Student he had worked on the coral reefs of the West Indies: he also studied the corals and reefs of the Indian and Ceylon regions. He revised the classification of the Astræidæ and published several valuable monographs, the most important of which was the British Museum Catalogue of this family (1928). Negotiations were in progress to enable him to undertake the preparation of a similar monograph on the Fungiid Corals. His death is a great loss to systematic and taxonomic zoology.

R. B. SEYMOUR SEWELL

WE regret to announce the following deaths:

Prof. Noah Morris, regius professor of materia medica and therapeutics in the University of Glasgow since 1937.

Dr. Wilfred H. Osgood, emeritus curator of zoology in the Field Museum of Natural History, and a corresponding member of the Zoological Society of London, aged seventy-one.

Dr. John Parkinson, well known for his work in economic geology in many parts of the British Empire and elsewhere, on July 19, aged seventy-five.

NEWS and VIEWS

Prof. E. P. Cathcart, C.B.E., F.R.S.

Prof. E. P. Cathcart retires from the regius chair of physiology, University of Glasgow, this summer after having completed almost twenty years service in the senior chair of the Institute of Physiology. The previous nineteen years he spent as Gardiner professor of physiological chemistry in the same Institute. Cathcart matriculated as a student in 1895 and graduated M.B., Ch.B. in 1900. Four years later he took his M.D., and in 1906 received the degree of D.Sc. Periods of foreign study were passed in Munich, Berlin and Petrograd (with Pavlov), and with F. C. Benedict at the Carnegie Institution at Boston. It was in 1905 that Cathcart was appointed Grieve lecturer in physiological chemistry in his *alma mater*: then from 1915 until 1919 he was professor of physiology in the London Hospital Medical School. During the First World War he occupied an important post in our anti-gas measures and held the rank of lieutenant-colonel. Afterwards he became a member of the Army Advisory Committee on Nutrition and on Hygiene. He was also a member of the Technical Committee on Nutrition of the League of Nations, and served on the Medical and Agricultural Research Councils. He was for many years a member of the General Medical Council. Among the other posts which he has held, his chairmanship of the Industrial Health Research Board and of the Scottish Health Services Committee are probably the most outstanding.

Cathcart's main lines of inquiry have been directed to the study of the physiology and efficiency of muscle work, and to the physiology of starvation and protein metabolism. His inquiries into the national diet and those of its constituent classes were models of their kind, and his advice was much sought after by Government departments. His most important publication was probably his monograph on "The Physiology of Protein Metabolism". Many have regretted that he did not publish editions other than the first. Cathcart belongs to the now very small group of men who have a wide interest in physiology in all its branches. He has a rare gift of inspiring and encouraging the best efforts of his junior colleagues. To the outsider he has always presented a rather gruff exterior, and he did not tolerate fools gladly; once admitted to his friendship, he was the staunchest of friends. In 1913 Prof. Cathcart married Miss Gertrude Norman Bostock, herself a doctor and one who has contributed to the physiology of metabolism in papers to the *Biochemical Journal*. She has been a most devoted and active wife, and her contribution to the welfare work of the University of Glasgow Settlement has been outstanding.

Prof. R. C. Garry

Prof. Robert Campbell Garry has been appointed to succeed Prof. Cathcart in the regius chair of physiology at Glasgow. Prof. Garry, who was the most distinguished graduate of his year (1922) in the University of Glasgow, obtaining his M.B., Ch.B. degree with first class honours, has held the chair of physiology at University College, Dundee, since 1935. After a period of training both in research and teaching in the Physiology Laboratory of the University of Glasgow and at Freiburg under the late Prof. Paul Trendelenburg and with Prof. Lovatt Evans at University College, London, he was appointed in 1933 head of the Physiology Department of the Rowett Institute in Aberdeen. This post he held until his promotion to Dundee. Prof. Garry has had considerable experience in administration work, as he has served for two terms of three years as assessor on the University Court of the University of St. Andrews and as an elected representative on the Council of University College, Dundee. He has always, since his earliest days in the Physiology Department of the University of Glasgow, been interested in the popularization of science, and was one of the pioneer lecturers in physiology to classes organised by the Workers Educational Association. This work, as well as his series of school broadcasts, was most successful. Prof. Garry has always been a keen research worker; in his early days his activities were directed to applied physiology, and latterly they have in the main been turned to general experimental work, particularly to the relation of the caudal region of the large bowel, and more recently to problems of nutrition. He is an editor of the newly founded *British Journal of Nutrition*. Prof. Garry was elected in 1943 a member of the editorial board (and is now chairman of the board) of the *Journal of Physiology*. He was elected a fellow of the Royal Society of Edinburgh in 1936 and was a member of its Council during 1938–41.

East African Institute of Social Research: Lieut.-Colonel W. E. H. Stanner

The Secretary of State for the Colonies has appointed Lieut.-Colonel W. E. H. Stanner to be director of an East African Institute of Social Research, the establishment of which is to be financed from a grant of £66,915 made in November 1945, under the Colonial Development and Welfare Act. The Institute will be associated with Makerere College, Uganda, which is being developed into the University College of East Africa. Colonel Stanner, an Australian, who is forty-one years old, is a graduate of the University of Sydney and a Ph.D. of the University of London (London School of Economics). He has carried out extensive field research in social anthropology in northern Australia and in Kenya. Recently, he has been engaged on research in the South Pacific on behalf of the Institute of Pacific Relations.

Redwood Medal of the Institute of Petroleum

The Redwood Medal of the Institute of Petroleum has been awarded to H. S. Gibson, general fields manager, Anglo-Iranian Oil Co., Ltd., Abadan, for his unique work on the production of petroleum. Established in 1921 in honour of Sir Boverton Redwood, founder-president of the Institute, the Redwood Medal is awarded "to a petroleum technologist of outstanding eminence, irrespective of nationality or membership of the Institute". Only seven previous awards have been made since the medal was instituted, the last being in 1938. Mr. H. S. Gibson served in the First World War in France, Egypt, Salonica and Turkey, and was mentioned in dispatches. On demobilization in 1919 he went to Emmanuel College, Cambridge, where he took the Mechanical Science Tripos. In 1922 he joined the (then) Anglo-Persian Oil Co., Ltd., as production engineer, and advanced steadily until in 1945 he was made general fields manager. He was awarded the C.B.E. in this year's King's Birthday honours.

Detection by Radar of a New Meteor Shower

British Astronomical Association Circular No. 282 gives a short note from Dr. A. C. B. Lovell, director of radar research on meteors at the University of Manchester, who has announced the discovery of a new shower during daylight. For some time radio reflexion has been used to study the ionization caused by meteors in the upper atmosphere (see *Nature*, July 19, pp. 74 and 76). Certain radiants have been selected and studied carefully by means of a beam of radiation about ± 6° wide which can be directed to any point in the heavens, and Mr. J. A. Clegg has devised a method by which it is possible to determine very accurately the radiant of a stream. No details about this method have been published up to the present, but it may be assumed that it is capable of providing more accurate results than those obtained from visual observations. It is interesting to know that the investigation of the radiants of the well-known showers during the autumn and winter shows, apart from minor variations, that the radiants determined by Mr. J. P. M. Prentice, director of the Meteor Section, British Astronomical Association, and his colleagues, agree closely with those found by Mr. Clegg's method.

The investigation of the η Aquarid stream was commenced on May 1, and it was obvious that this well-known stream was merely the beginning of a very active belt stretching towards the sun, the main radiant point of this stream lying in the constellation of Pisces. As this latter radiant crossed the meridian at about 10h.–11h., depending on the period of observation in May, no knowledge of this shower was possible from visual observation. The Aquarius end of this belt disappeared in mid-May; but the Piscid radiant continued with great intensity, and on June 22 the shower, which had continued for 35 days, was still active, the radiant being now in Taurus, and showed no signs of ending. While fluctuations in intensity have occurred, the hourly rate at transit has often exceeded 80 and has never fallen below 20. Preliminary analysis has given the following approximate positions of the new radiant:

May 7	R.A.	1h.	20m.	N. Dec.	20°–25°
June 22		4	40		20 –25

Minor radiants have also appeared for a few days about 15° W. and 10° E. of the main knot, but at the same declination, and on some occasions the whole area between these extremes has been active.

Institutum Divi Thomæ: Extension of Facilities

The Donner Foundation, Inc., the head of which is William H. Donner, of Philadelphia, has given a 64-room building in Palm Beach, Fla., to the Institutum Divi Thomæ, of Cincinnati, Ohio, for scientific research. The building, to be known as Donner Hall, was formerly a part of the estate of the late Colonel E. R. Bradley, and is adjacent to Bradley Hall, now occupied by the marine biological laboratories of the Institutum Divi Thomæ. Dr. George S. Sperti, director of the Institutum, states that Donner Hall will provide quarters for what is planned eventually to be the largest marine biophysics laboratory in the world; the Institutum already maintains a floating laboratory, the *Aquina*, which will become part of this programme. Secondly, since cancer in its simplest terms is a problem in cell division, and since lower forms of sea life offer convenient material for studying cell reproduction, Donner Hall will provide for intensive fundamental research in cancer. Finally, it will provide quarters for visiting scientific workers from various parts of the world, who will be invited to participate in a series of symposia devoted to different fields of research. The Institutum Divi Thomæ, founded in 1935 by the Most Rev. John T. McNicholas, Archbishop of Cincinnati, as a graduate research school, open to all scientific workers regardless of race, colour or creed, now has fourteen affiliated units throughout the United States; it has already been responsible for important work in various fields, notably biochemistry and biophysics. William H. Donner, whose generosity has opened the way to the establishment of the new cancer research centre, has previously given large sums for the study of cancer. He was born in Columbus, Ind., in 1864, and is a Presbyterian. Beginning as treasurer of the National Tin Plate Company at Anderson, Ind., Mr. Donner built its plate works near Pittsburgh and founded Monessen, Pa., before the company was absorbed by the American Tin Plate Company. He then built up another steel corporation in the same way until it became part of the Union Steel Company, which in turn was purchased by the United States Steel Corporation.

Television in the United States

The Radio Corporation of America has played a prominent pioneer part in the practical development of television in the United States, more particularly since 1923, when Dr. V. K. Zworykin applied for a patent on the now world-famous iconoscope. Much of this pioneer work has been inspired by Brigadier General Sarnoff, president of the Radio Corporation of America, and it is the purpose of an illustrated booklet recently issued by the Information Department of the Corporation (New York, 20) to present excerpts from General Sarnoff's statements on the subject at various public meetings and demonstrations during the past twenty-four years. Much of the results of the work conducted in the research laboratories of the R.C.A. is described in scientific and technical papers published in various journals, including the *R.C.A. Review*, to which reference was made in *Nature* of September 14, 1946 (p. 373). The publishers of this *Review* have now issued a bibliography of technical papers on television by R.C.A. authors. This includes some 275 technical papers on television and closely related subjects published during the period 1929–46, and arranged generally in chronological order. This "Television Bibliography" is in the same handy size (about 9 in. × 6 in.) as the *R.C.A. Review*, and should prove useful and convenient to all those concerned with the study, development and application of television. It is to be regretted that while the references give the year and month of publication, they do not give the volume and page number of the journal in question.

Mesozoic Faunas of Peru

In 1941, Dr. William F. Jenks sent rich collections of fossils, made in the course of his field work in the Cerro de Pasco region of central Peru, to Dr. Otto Haas, of the American Museum of Natural History, New York, for identification. Ever since, a steadily increasing amount of Peruvian fossil invertebrates has been accumulating at the Museum. Collections made during 1943–46 by Dr. Norman D. Newell in central, eastern and southern Peru, by Mr. Bernhard Kummel in northern, central and eastern Peru, and by Dr. Jenks in southern Peru have since been added to that initial material, and it is hoped that additional collections will be brought in by a forthcoming expedition to Peru under Dr. Newell's leadership. Besides Palæozoic assemblages, to be studied and published separately, most of those collections are of Mesozoic age. The work of description is being divided among several specialists. So far, Dr. Raymond E. Peck and Mr. Reker have just finished a report on charophytes from various regions and horizons, intended for publication in the American Museum *Novitates*, Dr. John W. Wells will study the Anthozoa and Porifera, Dr. Newell has taken charge of the pelecypods, and Dr. Kummel will concentrate on Triassic cephalopods. Dr. Haas is studying the Post-Triassic cephalopods and the gastropods. Some important groups, especially the brachiopods, which are second only to the molluscs in number of specimens, are still waiting for specialists to undertake their study. The Instituto Geológico del Perú, the director of which is Dr. Jorge Broggi, is co-operating with the American Museum of Natural History in all this work.

Royal Commission for the Exhibition of 1851 : Overseas Scholarships 1947

The Commissioners of the Royal Commission for the Exhibition of 1851 announce the award of Overseas Science Research Scholarships for 1947 to the following, the recommending body appearing in brackets: E. Gorham (Dalhousie University, Halifax), for research in plant ecology at University College, London; W. A. Bryce (McGill University, Montreal), for research in physical chemistry at the University of Oxford; C. C. Costain (University of Saskatchewan), for research in physics at the University of Cambridge; D. R. Bowes (University of Adelaide), for research in geology at the Imperial College of Science and Technology, London; L. Riddiford (University of Melbourne), for research in physics at the University of Birmingham, or the University of Manchester; Miss June Lascelles (University of Sydney), for research in biochemistry at the University of Oxford; J. N. Dodd (University of New Zealand), for research in physics at the University of Birmingham; J. P. Teegan (National University of Ireland), for research in physical chemistry at the University of Cambridge; Dr. A. K. Saha (University of Calcutta), for research in physics at the University of Birmingham; Dr. A. B. Bhatia (University of Allahabad), for research in physics at the University of Bristol.

Leverhulme Research Fellowships: Awards for 1947

The following awards, among others, for research in the subject mentioned and tenable for periods up to two years, have been announced by the trustees of the Leverhulme Research Fellowships: *Fellowships*: R. C. Abraham, late district officer, Nigeria, modern languages of Ethiopia and Eritrea (renewal); Dr. R. Dennell, reader in experimental zoology, University of Manchester, structure and physiology of the luminous organs of the Decapoda; J. A. Ratcliffe, lecturer in physics, University of Cambridge, propagation of radio waves; Dr. R. Stoneley, lecturer in mathematics, University of Cambridge, elastic yielding of the earth. *Research Grants*: Dr. P. Allen, demonstrator in geology, University of Cambridge, comparative petrology and palæoecology of the European 'Wealden'; J. S. Barlee, biology master, Royal Naval College, Dartmouth, investigation into the status of certain birds in Ireland; Miss E. M. Brown, lecturer in zoology, Chelsea Polytechnic, London, parasitic dinoflagellates and other causal organisms of disease in fish; Dr. J. G. D. Clark, lecturer in archæology, University of Cambridge, economic and social prehistory of Europe since late-Glacial times; J. S. Gittins, principal, Aycliffe Approved School, Darlington, a survey of the mental characteristics of delinquent boys; Dr. J. Grant, medical officer of health, County Borough of Gateshead, a study of epidemic diphtheria; Dr. F. R. Irvine, administrative officer, Faculty of Science, University of Edinburgh, indigenous plants of West Africa and their utilization for local purposes; P. Slater, principal research officer, Social Survey, use of statistical methods in forecasting human behaviour. Information in connexion with Leverhulme awards can be obtained from the Secretary, Leverhulme Research Fellowships, 7 Bedford Row, London, W.C.1.

The Night Sky in August

Full moon occurs on August 2d. 01h. 50m. U.T. and new moon on August 16d. 11h. 12m. The following conjunctions with the moon take place: August 12d. 22h., Mars 2° S.; August 15d. 10h., Mercury 4° S.; August 22d. 18h., Jupiter 0·1° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Jupiter on August 18d. 13h., Mercury being 0·6° N. Mercury rises 1h. 22m. before the sun on August 1, but will not be an easy object to observe. It attains its greatest western elongation on August 3, and at the end of the month is a morning star, rising only 10 minutes before the sun. Venus rises 50 minutes before the sun on August 1 and practically at sunrise on August 31, and will not be well placed for observation during the month. Mars, in Gemini, is visible in the early morning hours, rising soon after midnight during most of the month. Jupiter, in the constellation of Libra, is visible in the early portion of the night, setting at 23h. and 21h. 06m. at the beginning and end of the month, respectively. Saturn, in conjunction with the sun on August 5, cannot be seen. The following occultations of stars brighter than magnitude 6 take place: August 14d. 03h. 21·5m., *A* Gemi. (*R*); August 24d. 20h. 29·0m., 88 *B* Ophi. (*D*). *R* and *D* refer to reappearance and disappearance, respectively, and the latitude of Greenwich is assumed. The Perseid shower of meteors attains its maximum about August 10–12; the radiant is close to R.A. 3h., Dec. + 57°.

Announcements

The opening on July 14 of an Exhibition at the Science Museum, South Kensington, arranged with the Chemical Society, the eleventh International Congress of Pure and Applied Chemistry and the Department of Scientific and Industrial Research to illustrate the achievements of British chemists during the past century and to show the uses of chemistry in everyday life, marked the beginning of the centenary celebrations of the Chemical Society. The exhibition is now available to the general public, and will remain open until September 30 (weekdays, including August Bank Holiday, 10 a.m.–6 p.m.; Sundays, 2.30 p.m.–6 p.m.).

Dr. Adrien Albert, who for the last nine years has been working at the University of Sydney on the physics and chemistry of drug action, has joined the staff of the Wellcome Research Institution, London, to initiate similar studies there.

An Example of 'Mimicry' in Fishes

Among the genera of Cichlid fishes peculiar to Lake Nyasa, *Corematodus*, comprising two species, is characterized by the dentition, which consists in each jaw of a broad file-like band of small pointed teeth. Otherwise these two species would be included in the large genus *Haplochromis*, of which more than a hundred, nearly all endemic, have been recorded from Nyasa. Among the *Haplochromis* and their related genera in Nyasa, many species have a colour pattern characteristic of the Lake and rarely met with elsewhere in Africa, namely, a dark oblique band from nape to caudal fin. *Corematodus tæniatus* Trewavas also has this pattern on a silver-grey ground; the largest specimen known is 19 cm. in total length. *C. shiranus* Blgr. has quite a different pattern, consisting of vertical, or nearly vertical, black bars extending from the back to near the ventral surface. This pattern is exactly similar to that of females and non-breeding males of the Nyasa species of *Tilapia* of the *T. squamipinnis* group; and *C. shiranus* reaches a length of 27 cm., which is one of the commonest lengths of the *T. squamipinnis* caught during the Fishery Survey of 1939[1].

The guts of six specimens of each species of *Corematodus* were examined. The intestine is long, narrow and coiled. In each case stomach and intestine contained nothing but hundreds of minute scales exactly like those which cover the caudal fin of so many Cichlid species of Lake Nyasa, including *Tilapia squamipinnis*. The efficacy of the double file of the jaws of a *Corematodus* in rasping scales from the caudal fin of a *Tilapia* can easily be demonstrated, and except for the loss of some scales, the tail can be pulled undamaged from between the closed jaws. It seems that *Corematodus* specializes in this curious diet.

The strong superficial resemblance of *C. shiranus* to *T. squamipinnis* must be very useful to the former, enabling it to swim unnoticed in the shoals of *Tilapia*. The relationship between the two fulfils the conditions required of model and mimic. *Tilapia* is abundant and swims in shoals, *Corematodus* is relatively rare and is solitary, and reaps the advantage of the resemblance.

It was not found possible to identify the scales in the gut of either species of *Corematodus* as being those of *Tilapia* or of one of the *Haplochromis* group. It would be interesting to know if the two species do, in fact, select as victims fishes resembling them respectively in colour-pattern. The *Corematodus* seen were caught singly, in hauls including numerous *Tilapia* and also some oblique-banded Cichlids.

The two species of *Corematodus* were exhibited some years ago with the species they resemble by Dr. Tate Regan, but until 1939 their habits, which give point to the mimicry, were unknown.

A Fungus Parasitic on *Coptotermes curvignathus*, Holmgr.

During the course of some observations designed to determine the most suitable conditions for maintaining the workers of *Coptotermes curvignathus* (the termite pest of *Hevea brasiliensis*) in captivity, the development of an unusually high death-rate in one of the treatments led to an examination which disclosed that the insects had been parasitized by an entomophthoraceous fungus. The causal organism was isolated, and cultivated without difficulty on standard media and on rice-bran.

Its ability to parasitize and kill *Coptotermes* workers has been established experimentally; a 100 per cent kill being obtained within 48 hours in trials in which the insects (maintained in Petri dishes on sterile soil) were supplied with infected rice-bran as a source of food, the presence of the characteristic hyphæ in the tissues of the insects confirming the cause of death. The mortality in the controls, fed on sterile bran, was 3 per cent during the same period.

Reference to the literature suggests a relationship between this parasite and the species of *Conidiobolus* isolated from *Nasutitermes* by Kevorkian in Cuba[1]. The Imperial Mycological Institute, to which a culture was sent, considers, however, that the Malayan fungus does not completely agree with the Cuban fungus as that was described; in particular, the primary conidia of the first measure distinctly larger, and it has not been observed to form the structure termed 'villose resting spores'. Pending comparison with authentic material, it is regarded tentatively as a new species of *Conidiobolus*.

A Disease of Pyrethrum in Kenya

The demand for pyrethrum (*Chrysanthemum cinerariifolium*) resulted in a greatly increased production of this profitable crop in Kenya during the War. It has been cultivated commercially in Kenya since 1928. From 1,864 tons in 1938, the yield rose to 7,409 tons from 52,837 acres in 1945. This acreage is concentrated in a few areas in the Highlands, most of it at an altitude between 6,000 ft. and 9,000 ft. Minor losses, due to root and crown rot, are of common occurrence, but until 1946 the crop had escaped any serious disease in spite of the continuous and intensive cultivation to which it has been subjected.

The most important of the higher yielding areas is on the Mau Escarpment, where in June 1946 a serious falling off in yield, estimated in some instances to be as high as 80 per cent, occurred. Although the plants themselves appeared healthy, the flower buds failed to develop on account of an attack by the fungus *Ramularia bellunensis* Speg.[1]. By the end of the year, the disease had spread to all the main pyrethrum areas with the exception of the Nyeri–Nanyuki area on the slopes of Mount Kenya, which, up to the time of writing, had remained free.

Although typically a disease of buds and flowers (see illustration), rarely extending beyond the apical inch or so of flower stalk, the disease has been found infrequently on the foliage. Here no definite spots are formed, but the infection starts from the tip of the leaf segments and extends inwards.

Ramularia bellunensis Speg. on *Chrysanthemum cinerariifolium*. × 2 approx.

R. bellunensis has been recorded as causing a disease of *Chrysanthemum frutescens* in Italy in 1929[2] and in England in 1938[3]. In Italy, leaves and unopened inflorescences of pot plants in a greenhouse were severely affected. In England, the foliage in all stages was attacked, the lesions extending inwards from leaf tip and margin. The fungus does not appear to have been recorded on *C. cinerariifolium*, although both the fungus and this host are believed to be endemic in the Mediterranean region.

The immersed stromatic bodies from which the conidiophores arise are abundantly developed on the inner surfaces of the involucral scales, fragments of which are readily distributed with the seed.

This is, perhaps, another example of an exotic fungus finding a ready victim and a more congenial environment than hitherto recorded. Its advent is regarded by the pyrethrum industry of Kenya with apprehension.

Meiosis in Bougainvillea

A QUERY concerning the possibilities of crossing various horticultural varieties of Bougainvillea led me to examine meiosis in several of the more important ones available in Jamaica. Six varieties, Snow White, Formosa, Dark Purple, Ruby, Orange King and Royal Purple, were used. The first three have been assigned to the species *Bougainvillea glabra*, the next two to *B. spectabilis*, and the last is reputed to be a cross between unknown *glabra* and *spectabilis* types. In all six varieties, the chromosome number was found to be $2n = 34$. None of the available chromosome number lists gives any number for *B. spectabilis*, but Darlington and Ammal[1] list *B. glabra* as $2n = 20$. Since a counting error of 14 chromosomes is unlikely, it seems probable that the horticultural glabrous types are not directly derived from the true *B. glabra* but are species hybrids resulting from doubling in an $(x = 10) \times (x = 7)$ type. There is, however, little direct evidence for this assumption.

Cytologically, four of the varieties studied behave as regular diploids with 17^{II} at first metaphase and subsequent normal segregation (see table). All four are also fertile but apparently not completely so, as the seed set under natural conditions is not high. The remaining two types, Ruby and Orange King (the latter of which is reputedly a bud sport of the former), are meiotically irregular with most first metaphase plates showing from four to six univalents. These univalents follow the bivalents to the plate and then split. Of the resulting chromatids, about a third fail to be included in the daughter nuclei, but ultimately give rise to micro-nuclei in the tetrads. Chromatids included in the first telophase nuclei split again at second anaphase, but complete separation often fails and thus gives rise to second anaphase chromatin bridges. Both Ruby and Orange King appear to be completely sterile.

It is therefore tentatively assumed that the horticultural varieties of Bougainvillea are amphidiploids, and that a species (*B. spectabilis* ?) with a basic number of $x = 7$ should exist. In view of the horticultural importance of this genus, further investigation is indicated.

	Royal Purple	17	34	Fertile	Regular with 17^{II} at M^{I}	

A Rapid Nigrosine Method for Chromosome Counts Applicable to Growing Plant Tissues

FOR a plant-breeder dealing with plants which can be cross-fertilized who desires to work up polyploid material on a large scale, annual control of the purity of the polyploid stocks as regards chromosome number is necessary. A breeder of fruit and forest trees should also have at his command methods by which the chromosome numbers in new artificial or spontaneous crosses can be simply separated.

A grading of the polyploid chromosome number groups only requires an estimation of the number of chromosomes in the genome (for example, in *Beta*, 36 ± 2–4). Further, chromosome counting should be possible at any time in the whole vital cycle of the plants (including pollen mother-cells) and by the same simple method. In the method described below the treatment is essentially the same for roots as for leaves and flower-buds. Any deviations between them are noted in their proper connexion.

Fixing. Fix in 1 part of concentrated (98 per cent) acetic acid + 2 parts of 95 per cent alcohol for about 24 hours. Roots should be fixed in a cooled fluid.

Loosening of the tissues. Replace the fixing fluid with a cooled mixture of 1 part of concentrated hydrochloric acid (sp.gr. 1·27) + 2 parts of 95 per cent alcohol. Roots are treated for 8–10 min. For leaves the character of the tissues will decide the concentration and time: *Beta*, 1 : 2 for 7–8 min.; *Pisum*, 1 : 4 for 5 min.; *Pyrus* and *Betula*, 1 : 1 for 10 min.; flower-buds, 1 : 10 for 5–8 min.

Washing. Replace the loosening fluid with distilled water and preserve in a cool place for 15–30 min. (thick leaf tissues and body complexes for 60 min.).

Staining. Place four or five roots on an object glass. Cut away portions not showing divisions; suck off. For a leaf specimen, take a *small* piece from the base of a leaf on a quickly growing part of the stem. Squeeze flower-buds into pieces so that large portions of the bracts are picked off with a pincette. One drop of staining solution is added. With an ordinary piece of stiff eraser rubber (*a*) tap gently on the cover glass, (*b*) press fairly gently over the whole cover glass, (*c*) press hard with short vibratory movements, (*d*) lift the cover glass until the staining solution flows in over the tissues. Considerably less pressure is used for leaves. Pollen mother-cells are pressed still more gently. For roots the staining time is 1–2 min. The staining fluid should be cool. Leaves of *Pisum* are stained for 30 sec., *Beta* 40 sec., those of *Pyrus* and *Betula* for 45–60 sec. For these types of tissues, 4 per cent staining fluid is used; for buds, 3 per cent solution. The pigment colours the chromosomes quite black and the plasm a faint grey.

After staining, pass a rubber roller to and fro some ten times over the cover glass, on which a filter-paper is laid.

Staining fluid. Prepare a 4 per cent solution as follows: dilute 50 c.c. of concentrated (98 per cent) acetic acid with distilled water to 100 c.c. Heat to boiling-point. Add, continuously stirring the while, 4 gm. of spirit-soluble nigrosine[1]. Boil for 3–5 min. to a weak tarry consistency. Cool and filter immediately. Keep the solution in a closed glass vessel at room temperature for about 10–14 days before use.

Two girls previously quite unacquainted with cytological and similar technique are using this method at Hilleshög. To-day their capacity is 100–120 plant-counts on root-tips per working day of seven hours. Leaf-counts can be made even more quickly than root-counts (150–200 plants per day).

Feeding Mechanism of Water-bugs

AN account has been given by H. D. Slack of the cibarial suction pump of Corixidæ, in which a modification producing the effect of chitinous jaws was noted[1]. A full account of the head and mouth parts of *Rhamphocorixa acuminata* has been previously given by M. E. Griffith[2]. Further, H. B. Hungerford[3] has found solid food in the alimentary canal of Corixidæ, in particular, jaws of rotifers, filaments of *Oscillatoria* sp. and *Mougeotia* sp., slime diatoms, etc. In an investigation begun in 1943, I have confirmed much of this work, and, in addition, have found legs of Crustacea, *Anabæna* sp., undamaged filaments of *Spirogyra* sp., an unexploded nematocyst, pollen grains, etc. I have also made observations on the feeding of *Sigara striata*, *S. falleni*, *Corixa punctata* and *C. panzeri*, on chironomid larvæ, Mayfly nymphs and daphnids. In all cases the live food was pierced and anchored by the mouth parts, probably by the mandibular teeth described by M. E. Griffith[2]. The food thus seized was held for periods varying from five to twenty minutes, during which time some of the contents of the living animal were sucked into the corixid. On one occasion black pigment from the eye of a daphnid was observed streaming through the pharynx.

H. D. Slack suggests that the cibarial 'teeth' probably have the function of comminuting the solid food ingested, a function also attributed to the masticator described by Griffith. This may be so; but in many instances the contents of the mid-gut are found to be remarkably intact, while the finely comminuted food there is usually identical with the detritus upon which corixids frequently feed.

That there is a difference in chitinization between early instar nymphs and adults is in agreement with observations made by me on the instars of *C. panzeri*[4]. The general chitinization of the first and second instars is much less intense than in later instars and adults. An investigation of the gut contents of early instars indicates little difference in food ingested compared with that of later instars and the adult. Possibly, therefore, the heavier chitinization of the cibarial teeth in the adult is not due to a change in diet, but is part of a general increase in body chitin. An investigation of the histology of the alimentary canal and nutrition of Corixidæ was begun in 1943, and the results are shortly to be published.

Individual Activity of Ants

FOLLOWING the publication of my note on the "Division of Labour in Ants"[1], Dr. T. Cunliffe Barnes of Philadelphia has directed my attention to his paper on "The Rhythms of Activity in Ant Colonies"[2], of which I was previously unaware.

In the course of his experiments, Dr. Barnes observed "that certain restless individuals in the group [of ants] were constantly arousing inactive individuals to activity by touching them with the antennæ". Brief details of the occurrence of this phenomenon in two experiments are given. These restless 'catalyst' ants of Dr. Barnes are the equivalent of the 'excitement centres' in my theory of the division of labour. Although Dr. Barnes did not study the behaviour of his ants in relation to the division of labour, but was only concerned with the activity or inactivity of individuals and groups, it is of considerable interest that when the ants were placed in artificial nests where they had no occupation (or queens ?) certain individual ants showed greater physical activity than others, and were capable of stimulating the whole group of ants into similar activity. Thus even when the ants are not employed in any occupation, they may still be stimulated into undirected physical activity by individuals acting as 'excitement centres'. It would be interesting to know how far this individual liveliness is correlated with hard-workingness and laziness when ants are engaged in definite tasks (see Chen[3]) and with the ability to learn (see Schneirla[4]).

A New Locality for *Cyprinodon dispar* Rueppel

IN the winter of 1943–44, large shoals of *Cyprinodon dispar* Rueppel appeared in shallow water near the shore off Tel-Aviv. In the summer of 1944 they were found to be abundant in the salt pans of Athlith, south of Haifa. *Cyprinodon dispar* has not hitherto been reported from the Mediterranean Sea.

The marine specimens differ distinctly in body-shape and colour from specimens from the brackish springs in the neighbourhood of the Dead Sea. A detailed description will be published elsewhere. Specimens of both populations were kept in aquaria under like conditions and bred true to type.

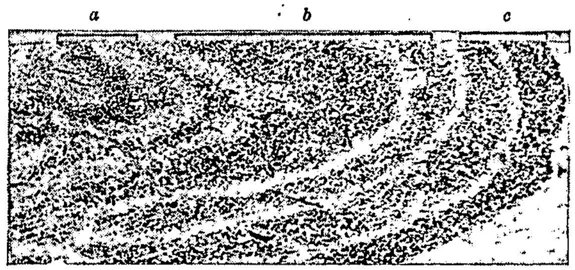
A Possible Central Mechanism for Colour Vision

SOME years ago, one of us submitted evidence to show that the conducting unit from the central area of the retina in man and the higher primates is a three-fibre unit[1]. It was further suggested that this anatomical fact might be related to the trichromatic theory of colour vision. Recently we have been making a detailed analysis of the main visual centre, the lateral geniculate nucleus, of the human brain, with special reference to its laminar pattern, the relative extent of the several cell layers, and their distribution over the projection areas corresponding to different parts of the retina.

In the central retinal area of the nucleus there are three cell layers related to each eye. These layers may be called *a*, *b* and *c* (the *a* layer, which is the most superficial, being composed of much fewer and larger cells). The component fibres of the three-fibre unit ending in these layers may also be called *a*, *b* and *c* fibres. It is now possible to make the following statements with reference to the human retina and geniculate nucleus. From the central area of the retina the conducting unit is a three-fibre unit consisting of *a*, *b* and *c* fibres. At the fixation point the unit consists of *b* and *c* fibres; *a* fibres are relatively very few (or may be absent altogether). From the peripheral retina there is also a functional unit of two fibres, here represented by *a* and $(b + c)$—that is to say, one fibre of the unit terminates in layer *a* and the other in a region of the geniculate nucleus formed by a fusion of layers *b* and *c*. If we assume (as we believe our evidence permits us to do) that there are not great variations in the fibre-cell ratio in the geniculate nucleus, we can also say that, taking the retina as a whole, the *a* fibres are much fewer than the *b* or the *c* fibres; on the other hand, the relative number of *a* fibres increases progressively towards the periphery of the retina. Lastly, from the central area of the retina, *c* fibres preponderate over *b* fibres.

We are well aware of the complexities of colour vision problems, and we ourselves do not feel competent to discuss them. Nevertheless, for the consideration of those who are better qualified in that respect, we would like to put forward the following points. If it be supposed that the *a* fibres correspond to the blue factor of trichromasy, this would explain their proportionate increase towards the periphery of the retina, which fits in with the observation that, in the distribution of colour sensitivity over the field of vision in moderate illumination, blue has the widest extent peripherally. The fact that, over the retina as a whole, the *a* fibres are much fewer than the *b* or *c* fibres corresponds with the fact that, as shown in photopic visibility curves, luminosity is least in the blue part of the spectrum and reaches its maximum in the yellow part (that is, the part representing, according to the trichromatic theory, a fusion of the red and green factors). The paucity (or possible absence) of the *a* fibres from the foveal centre accords well with the evidence that here the retina is relatively insensitive to blue. Lastly, it has been found[2] that if monkeys are kept for some weeks in light from which the blue end of the spectrum is completely excluded, the cells in the central retinal zone of cell layer *a* may undergo marked atrophic changes.



SECTION OF THE LATERAL GENICULATE BODY OF A MONKEY SHOWING SELECTIVE CELL ATROPHY IN THE CELL LAYER *a* WHICH RECEIVES CROSSED RETINAL FIBRES (THAT IS, THE FIRST LAYER ON THE LEFT IN THE PHOTOGRAPH). × 20

In the accompanying microphotograph this selective atrophy is well shown; for reasons which are not apparent, it is mainly limited to the layer which receives crossed retinal fibres only. It should be noted, also, that some degree of cell atrophy may affect the central zones of layers *b* and *c*, but this is less conspicuous than in layer *a*. If the *b* and *c* fibres are related to the red and green factors of trichromasy, then the fact that the functional conducting unit for the peripheral retina consists of *a* and $(b + c)$ fibres explains the observation that in the field of vision the area of sensitivity for yellow extends farther than that for green or red separately; for the impulses from the receptors related to the *b* and *c* fibres would be conveyed to a common mass of geniculate cells (formed by the fusion in that area of layers *b* and *c*) and would thus not be kept segregated in the visual paths beyond the geniculate level.

We would suggest that these correlations (together with those reported in a previous paper[1]) offer further presumptive evidence that the six-layered pattern of the geniculate nucleus (that is, two sets of three layers for the two eyes) may be related to colour vision. However, further and more detailed correlations need to be established, and much more experimental evidence is required in order to put our thesis to a crucial test.

Intramural Vessels in the Retina (Vasa vasorum)

Investigating ocular tissue of man and of some animals by a clearing method during the last seven years, I have found intramural vessels in retinal arteries and veins. They were discovered in bulk specimens, their existence proved later on by reconstruction of serial sections. Intramural vessels in the retina run within the wall parallel to the lumen or encircling it or in spirals around it. They often branch and the twigs frequently reunite. I have not found them so far in the retinal vessels of young healthy human beings. Intramural vessels have been described in atheromatous diseased coronary arteries of the heart[1]. The purpose of these newly built retinal vessels in some cases may be to bypass an obstacle in the bloodstream. In other cases with intramural vessels, however, the retinal arteries show hyaline sclerosis with preservation of the lumen. It is possible that in the latter case the intramural vessels act as vasa vasorum and improve the insufficient nourishment of the changed vessel wall. They are considered as an attempt at healing of the sclerotic process. A detailed account of these findings will be published elsewhere.

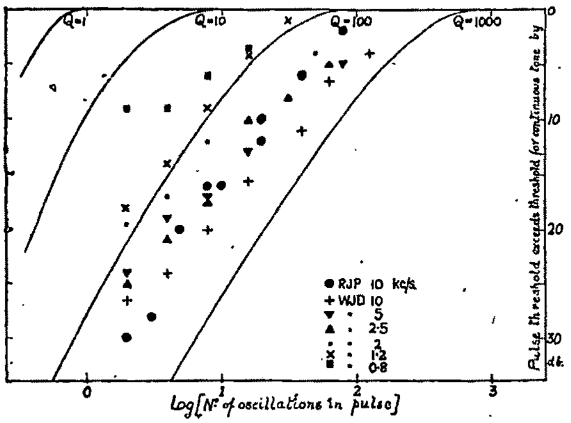
Transient Reception and the Degree of Resonance of the Human Ear

It is now more than eighty years since Helmholtz[1] gave a functional explanation of the architecture of the cochlea, and at the same time supplied a plausible physical basis for the extraordinary pitch discrimination of which the human ear is capable. Recent authorities have, implicitly or explicitly rejected Helmholtz's explanation of pitch discrimination. For example, Stevens and Davis[2] say "Everything considered, then, we must conclude that the inner ear is highly damped and that this damping impairs its resolving power in the analysis of sound waves" (p. 287); and elsewhere it is implied that the damping is critical. We cannot here consider the evidence adduced by Stevens and Davis and by others in favour of high damping of the cochlea, and must limit ourselves to the blunt statement that it is inadequate. It is the purpose of this letter to put forward evidence, independent of pitch discrimination, which unequivocally supports Helmholtz's original belief.

We shall use the familiar parameter Q to describe the behaviour of resonators. For all simple resonators there is a resonant frequency, f_0, and a value of Q which is finite and positive. If such a resonator is in forced oscillation, and the frequency of the impressed force is altered from f_0 to $f_0 \pm (f_0/2Q)$, the oscillatory energy stored in the resonator is halved. Q is a measure of the selectivity of the resonator, and when Q is small the resonator is said to be heavily damped. In particular, when $Q = 0{\cdot}5$, it is said to be critically damped. For $Q > 25$ the resonator is said to be lightly damped, and when the impressed force is removed the resonator will continue to oscillate at a frequency which differs from f_0 by less than 1 per cent, and with an amplitude diminishing by $1/e$ every Q/π cycles.

Now let it be assumed that the fibres of the basilar membrane are lightly damped and independent resonant elements arranged, as Helmholtz supposed, like piano wires in ascending order of frequency from the apical to the basal end of the membrane. Further, let it be assumed that for each fibre a particular finite amplitude of oscillation is necessary to produce an audible sensation. Then, if the threshold sound intensity for a continuous pure tone is known and if a value for the Q of the fibre resonant to that tone is assumed, the threshold of audibility for a pulse consisting of any integral number of half-periods can be predicted. Conversely, if the threshold for such pulses can be measured experimentally, the Q can be determined.

We have performed this experiment for a number of frequencies between 1 and 10 kilocycles per second, and for pulse-lengths ranging from 2 oscillations to 250 oscillations. In the accompanying figure the smooth lines are calculated for a number of values of Q. The points are experimental determinations at the frequencies indicated. Considering the well-known difficulty of obtaining reproducible results from subjective auditory measurements, the scatter is small and the agreement with the predicted slope satisfactorily close. We are therefore justified in ascribing to the resonators of the cochlea a Q of about 200–350 from $2\frac{1}{2}$ to 10 kilocycles, falling to about 50 at 1,000 cycles. For technical reasons we have not been able to make measurements at frequencies much below 1,000 cycles, but it is extremely likely that the Q continues to fall with frequency. If it were the same at 100 c./s. as at 10,000 c./s.,



the resonator at the lower frequency would 'ring', when the stimulus ceased, one hundred times as long as the resonator at the higher, with a consequent blurring of the appreciation of changing intensity at low frequencies. The number of discriminable intervals of pitch per octave at the lower end of the spectrum is about one twentieth of the number at the upper end[3]. Moreover, Bürck, Kotowski and Lichte[4] found that three or four oscillations are sufficient to produce a recognizable sensation of pitch at 50 c./s., whereas 250 oscillations were required at 10 kc./s. Both these facts support the belief that the Q may be 10 or less, at the extreme apical end of the cochlea.

It remains to show that the values of Q we find are adequate to explain pitch discrimination. We know already that the least perceptible increment in the intensity of a 10 kc./s. pure tone is of the order of 2 decibels, corresponding to an amplitude change of approximately 30 per cent. We assume that the resonators are equal in number to the inner row of hair cells and their resonant frequencies are distributed correspondingly to the distribution of discriminable pitch intervals; that is, there are roughly 2½ resonators per discriminable pitch interval, and at 10 kc. a density of 470 resonators per octave. At this frequency, a frequency change of 50 c./s. can be detected. But, if the Q of the resonators is 200 and one of them responds with unit amplitude to a pure tone at its resonant frequency, the respective amplitudes of its nearest, nearest-but-one and nearest-but-two neighbours will be respectively less than unity by 25, 45 and 60 per cent, a difference more than adequate to account for the frequency discrimination actually found. A large part of the margin would, however, vanish if allowance were made for fortuitous irregularities in the series of resonators.

It is clear, therefore, that a quantitative explanation of pitch discrimination above 1,000 c./s. is possible if, and only if, our findings for the Q of the ear are of the right order. The assumption of high damping involves the complementary assumption of a far finer intensity discrimination than is either plausible or consistent with experimental data.

Crystalline Bacterial Catalase

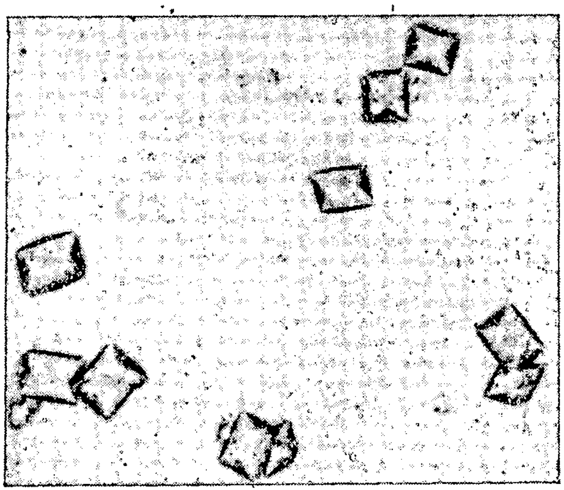
It is now fifty-four years since Gottstein[1] discovered that some bacteria are able to decompose hydrogen peroxide with evolution of gaseous oxygen, an activity he attributed to their possessing an intracellular enzyme which later came to be called 'catalase'. Since then much work has been done on bacterial catalase; but none of it has been directed towards elucidating the chemical nature of the enzyme and no attempts have been made to isolate it in a pure state from any micro-organism. A similar state of affairs exists in regard to the majority of the intracellular enzymes of bacteria, which have been little studied in comparison with their counterparts in animal tissues. One reason for this is undoubtedly the technical difficulty of liberating such enzymes from the bacterial cell. Most of the techniques hitherto used for destroying the cell wall and liberating intracellular enzymes (for example, autolysis, drying, shaking with glass beads or grinding with powdered glass, the roller-crushing mill, ultrasonic disintegration) either tend to be destructive of labile enzymes, are difficult to employ on a large scale, or require specialized apparatus.

A method having none of these disadvantages was first applied by Penrose and Quastel[2] in 1930, though it has been little used since; namely, lysis of bacteria by lysozyme[3]. This substance, which is easily prepared in crystalline form from egg-white[4], rapidly brings about smooth and complete lysis of susceptible bacteria; no specialized apparatus is required and the method can be applied on any scale.

Using this technique to liberate the enzyme, we have been able to isolate catalase from *Micrococcus lysodeikticus* in crystalline form. So far as we are aware, this is the first bacterial enzyme to have been crystallized. In outline, the technique of isolation is as follows. The bacteria are grown on C.C.Y. agar[5] in large enamelled trays, harvested, washed, suspended in 0·5 per cent sodium chloride, and lysed with crystalline lysozyme (1 mgm./gm. bacteria). The lysate is treated with 0·5 vol. alcohol at pH 5·6 in the cold, which precipitates large amounts of inert proteins and highly viscous substances formed on lysis. The supernatant liquid is shaken with 0·3 vol. chloroform which removes more inert proteins. Addition of ammonium sulphate (30 gm./100 ml.) to the supernatant liquid causes it to separate into two layers; the smaller top layer contains all the catalase. The chloroform treatment and 'layering' are now repeated, followed by dialysis to remove alcohol. The solution is now fractionated by step-wise addition of solid ammonium sulphate at pH 5·6; most of the catalase is precipitated between the limits 3·5–4 M, and is redissolved in about a tenth the original volume. It is now refractionated by careful addition of 4 M ammonium sulphate adjusted to pH 5·6. The main fraction is almost pure catalase; it is taken up in a minute amount of water and centrifuged; on standing at room temperature the enzyme crystallizes.

The crystals (see photograph) are always octahedra; no needle forms have been found. Identical crystals have been obtained by prolonged dialysis, but this is an inferior method as small amounts of protein impurity present are precipitated with the crystals.

Some bacterial enzymes (for example, lactic dehydrogenase) are known to have prosthetic groups different from their analogues in higher animals. Bacterial catalase, however, is remarkably similar to



CRYSTALLINE CATALASE FROM *M. lysodeikticus*. CRYSTALS FROM AMMONIUM SULPHATE. × *c.* 270

the crystalline catalases of horse, sheep and ox tissues.

The crystalline enzyme is an iron-porphyrin protein; its solutions have three absorption bands with centres at 6316, 5451 and 5060 A. Different preparations have contained 1·05–1·15 per cent hæmin (by direct estimation as pyridine-hæmochromogen). If the crystalline enzyme is pure, and contains four hæmin groups per molecule, the molecular weight is 226,000–248,000. Unlike animal liver catalases, all the prosthetic group is iron-protoporphyrin, and it appears to contain no verdohæmatin or similar substances producing blue pigments with acetone-hydrochloric acid. The enzyme has a greater activity than liver or blood catalase, the Kat-F.[6] being *c.* 90,000.

An interesting finding is the remarkably high concentration of catalase in *Micrococcus lysodeikticus*. From the catalase activities of the pure enzyme and the lysed bacteria, one can calculate that 100 gm. (dry weight) of this organism contain *c.* 2 gm. of catalase. Hence a single bacterial cell (dry weight taken as $2 \cdot 5 \times 10^{-13}$ gm.) contains *c.* 20,000 enzyme molecules. This amount of catalase would enable each cell to decompose about forty-seven times its own weight of hydrogen peroxide per minute (at 0° and a peroxide concentration of 0·01 *M*). Such large amounts of hydrogen peroxide could scarcely be formed as a result of cell metabolism, and it is difficult to devise any teleological explanation for this high enzyme concentration unless, as Keilin[7] has suggested, catalase has other functions besides the simple decomposition of hydrogen peroxide.

Barium Titanate Crystals

CRYSTALS of barium titanate ($BaTiO_3$), with linear dimensions up to ~2 mm., have been produced from solutions in carbonates and chlorides, and (when pure) are hard, clear, pale yellow in colour, and of cubic external symmetry. We are greatly indebted to Prof. P. Scherrer, Zurich, for advice on methods of producing these crystals. The results of optical and X-ray examination of the crystals are summarized below.

At room temperature the crystals are piezo-electric (established in co-operation with Dr. W. A. Wooster, of Cambridge, using the apparatus of Giebe and Scheibe), and consist of individuals with tetragonal symmetry (space group *P4mm*), twinned about the 101 and 011 planes. The exact arrangement and size of the twins vary considerably, and depend upon the purity of the material and the stresses involved during their formation. In a simple case, the crystal consists of two sets of individuals twinned so that the tetrad axes are inclined at an angle of $90° - \gamma$, where $\gamma = 35'$ and $90° \pm \gamma$ is the angle between the diagonals of the 010 face of the tetragonal unit cell. The twin boundaries have lower birefringence and probably consist of stress-distorted, tetragonal cells which are very nearly cubic.

Above ~120° C. the crystals have cubic symmetry, *Pm3m*, and specimens can be taken through this temperature without structural breakdown; that is, the crystals maintain their rigidity and external form throughout the transition. The arrangement of the twins in the crystal below 120° C. may vary from one cycle of changes to the next, and provided no external stresses are applied, depends on the rate of cooling. Over a certain temperature-range near 120° C., both cubic and tetragonal phases co-exist in the same crystal.

The twin arrangement is sensitive to both electrical and mechanical stresses, particularly at temperatures near the transition (~120° C.), and also near 0° C. where the axial ratio c/a has a maximum value[1]. This accounts qualitatively for the maxima of incremental permittivity observed at these temperatures. On the application of such stresses the twins re-orient themselves so as to reduce the resultant internal stresses, and this is achieved by an increase in the proportion of the crystal volume occupied by those twins having the longer (polar) tetrad axis perpendicular to the applied mechanical stress (assumed compressive) or parallel to the applied electric stress. The increase in volume of any component is effected by a displacement of the twin boundary in a direction perpendicular to the plane of the boundary.

The ferro-electric characteristics of barium titanate have already been established by Hulm and others (see following communication), and our optical and X-ray diffraction studies enable us to associate the individual single-crystal components with ferro-electric domains; in some cases truly single crystals, assumed to consist of a single domain, have been observed at room temperature, but they tend to be unstable, especially just below 120° C.

Work is now in progress from which we hope to establish the exact atomic parameters in the unit cell of this and some allied materials, so providing the experimental basis for the theoretical discussion of the spontaneous electric polarization observed. We also propose to investigate in detail the behaviour of these materials at temperatures below room temperature, where other crystallographic changes have been noted.

A full account of these researches will be published later.

Dielectric Properties of Single Crystals of Barium Titanate

THE dielectric properties of some of the single crystals of barium titanate prepared by H. F. Kay and R. G. Rhodes (see preceding communication) have been measured at various field strengths and temperatures. The average linear dimension of the crystals available was 0·4 mm., and it was found convenient to mount them in thin disks of a phenol-formaldehyde resin. Silver electrodes were vaporized on to the two exposed faces, and the electrical contacts were pressed against the silver on the resin, so as not to stress the crystal. The electric field was applied along a direction which was a cubic axis above the Curie point, and contained a mixture of the three tetragonal axes, in various domains, at room temperature. A circuit essentially similar to that of Sawyer and Tower[1] was used to display the polarization-electric field curve at 50 cycles per second on a cathode ray tube.

Typical hysteresis loops obtained at various temperatures are shown in Fig. 1. Such loops were photographed for a series of maximum field strengths at each temperature, and the curve of maximum polarization against maximum field strength shown in Fig. 1 was derived. At 18° C. the curve rises steeply with increasing field and then gradually flattens. The region *AB* presumably corresponds to complete orientation of the ferro-electric domains in the field direction; its small gradient is of the same order as the weak field susceptibility found with a Schering bridge, and is perhaps due to ionic distortion. By extrapolating *AB* back to the polarization axis, the permanent polarization characteristic of a single domain in zero field may be estimated as about 16 micro-coulombs per sq. cm., which is much greater than that of the other known ferro-electrics. The permanent polarization values for other crystals examined agreed within about 10 per cent, which is the order of uncertainty in measuring the effective area used; the coercive field, however, varied widely between crystals, from about 5,000 to 20,000 volts per cm.

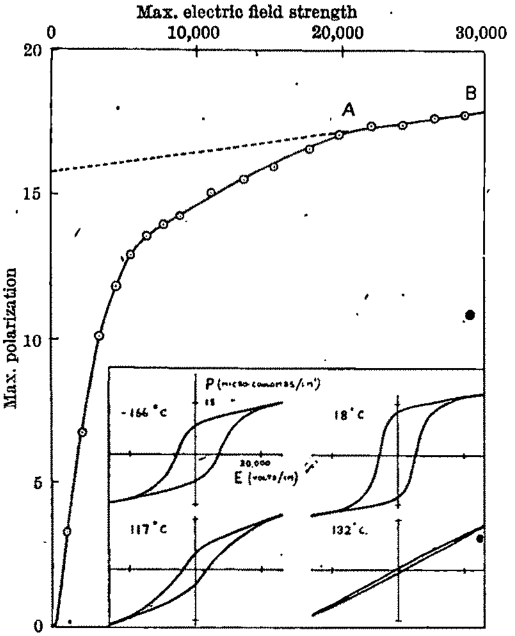

Fig. 1

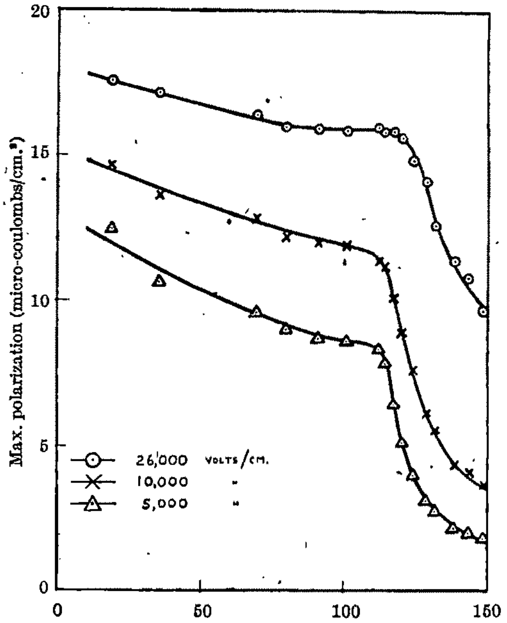

Fig. 2

Measurements on polycrystalline specimens by the same method show a maximum polarization of about 5·3 micro-coulombs per sq. cm. at 20,000 volts per cm., and similar results have been obtained by Wul and Goldman[2]. It is probable, however, that saturation for a polycrystalline aggregate is far from complete at this field strength, perhaps due to large internal strains which prevent complete alignment of domain directions in the fields available.

The behaviour of a single crystal at high temperatures is shown in Fig. 2, where maximum polarization is plotted against temperature for various field strengths. The polarization is fairly constant up to about 110° C., and then drops at a temperature slightly dependent on the field strength. Above about 130° C. the polarization – field relation becomes almost linear, though still corresponding to a very high dielectric constant which falls off according to a Curie–Weiss law. Estimation of the Curie temperature, at which hysteresis should disappear, is made difficult by an appreciable non-linear conduction above 100° C., which cannot be completely compensated and causes a slight apparent hysteresis. Detailed examination of the results suggests a Curie temperature of about 124° C., in good agreement with previous determinations on polycrystalline specimens[3].

Preliminary measurements down to 20° K. show that permanent polarization effects still exist at low temperatures; the coercive field is larger than at room temperature and the maximum polarization for a given field strength amplitude is smaller, probably due to incomplete saturation.

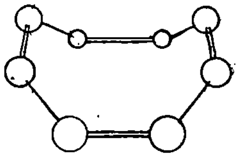
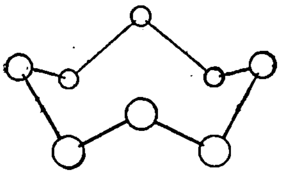
The 'Octa-Benzene', Cyclo-octatetraene (C_8H_8)

THE fact that cyclo-octatetraene—in contrast to benzene—shows a markedly unsaturated character has generally been used as an argument in favour of the assumption that the molecule contains alternate double and single bonds. The resonance energy, which is not much smaller per CH-group than that of benzene, makes the correctness of this assumption seem rather doubtful. On the other hand, a preliminary Raman analysis leads E. R. Lippincott and R. C. Lord, jun.[1], to believe that the spectrum can best be interpreted on the basis of a puckered eight-membered ring with alternate single and double bonds.

An electron diffraction analysis of the vapour carried out recently, using the sector method, leads to a different conclusion. This analysis indicates that all the C—C bonds are equivalent, and that the C—C—C angles are 120° just as in benzene. The C—C distance is not much greater than that of benzene (about 2 per cent).



a



b

The distribution curve ($\sigma(r)/r$) directly obtained from experiment was compared with theoretical curves based on the following models: (1) plane ring, (2) puckered ring with alternate double and single bonds, (3) puckered ring with equivalent bond, varying the C—H distance within a reasonable range. In case 3 only was satisfactory agreement obtained. The carbon skeleton of a model based on the assumption of alternate double and single bonds is reproduced in Fig. *a*, the carbon ring of the model resulting from the electron diffraction investigation in Fig. *b*. (It is, of course, possible that the bonds of Fig. *b* are not strictly equivalent. In this case, however, the difference between the two types of bonds is too small to be detected interferometrically.)

The 120° angle between C—C bonds indicates the presence of σ-bonds (ps^2-bonds). The additional π-bonds are based on p-orbitals perpendicular to the plane of the σ-bonds. The overlapping of two neighbouring p-orbitals is weaker than in the case of benzene because their directions are no longer parallel. It may thus be understood that the C—C distance is greater and the unsaturated character more pronounced than in the case of benzene.

We have further reinvestigated the Raman spectrum of cyclo-octatetraene. Our measurements in the frequency region below 2,000 cm.$^{-1}$ (that is, excluding the complicated region of hydrogen-stretching frequencies) are given in the accompanying table.

Frequency (cm.$^{-1}$)	Intensity	Polarization	
200 (broad)	8	*P*	
254	3	*D*	
298	3	*D*	
370	6	*D*	
659	1	*D* ?	
876·8	8	*P*	
953	4	*D*	
1209	6	*D*	
1220	2	*D* ?	
1442	6	*D*	
1459	0	—	1209 + 254 = 1463
1608	1	*D* ?	
1639	2	*D* ?	1442 + 200 = 1642
1655·5	10	*P*	
1748	0	—	2 × 876·8 = 1754

In agreement with Lippincott and Lord[1], we have found only three of the Raman lines to be polarized. We have, however, failed to observe several frequencies reported as weak lines by these authors. As seen from the table, three of the fifteen Raman lines observed by us may be explained as combination tones, leaving twelve frequencies to be interpreted as Raman active fundamentals. This is in agreement with the D_{4d} symmetry which requires three polarized and nine depolarized Raman lines in this frequency region. As a D_4 or a D_{2d} structure should give rise to five polarized and 18 resp. 17 depolarized lines, we believe that the Raman spectrum can best be interpreted on the basis of the D_{4d} model.

A Pulse Method for the Measurement of Ultrasonic Absorption in Liquids: Results for Water

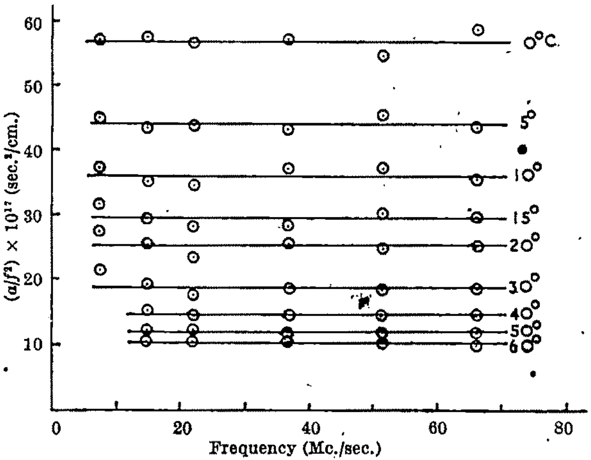
IT is well known that measurements of the absorption of ultrasonic waves in liquids[1-3] often do not show good agreement, and that for numerous liquids they indicate absorption coefficients many times those calculated on the assumption of a purely viscous loss. Because of these discrepancies it was considered useful to make measurements by a new technique, and one was chosen which would remove many of the possible objections to previous methods. A 'radar pulse' technique was developed, in which a short wave-train was emitted in a narrow pencil from a quartz oscillator; the sound, after travelling through the liquid, was reflected and received by the same quartz plate, which thus acted as a common 'transmit–receive' transducer.

The amplitude of the received pulse was measured as a function of the distance to the reflector. By driving the quartz crystal on its fundamental and 3rd, 5th, 7th and 9th harmonics, it was possible to measure absorption of waves on five frequencies from 7·37 to 66·1 Mc./s. A sixth frequency, 15 Mc./s., was added by changing the crystal. A feature of the technique was the elimination of errors due to diffraction; concordant measurements were made in both the Fraunhofer and Fresnel diffraction zones of the quartz disk. In the case of small absorption, that is at low frequencies, the reflector was placed in the Fraunhofer zone and the results suitably corrected[4]. It is not clear from published descriptions that due care in this connexion has always been taken in previous work.

The most important advantages of the pulse method arise from (*a*) the small mean powers which may be used, (*b*) the fact that waves which have travelled by different paths can be distinguished by the difference in their time of arrival. Many of the previous methods, especially those based on acoustic radiation pressure, require a comparatively large power, which leads to heating of the liquid, the production of cavitation, and 'streaming' of the liquid. In the pulse technique the mean power, responsible for the phenomena just described, may be kept very small; in these experiments it was about one milliwatt. Moreover, in methods employing continuous waves, it can never be entirely certain that some of the effects attributed to energy loss in the liquid (true absorption) are not due to loss of energy by scattering out of the beam. The pulse method is particularly suitable for the detection of scattered radiation, and it was easy to show that no measurable intensity of sound was scattered backwards from the liquid in front of the crystal. In addition, a direct test, using a separate receiving crystal, was made to see if any energy was scattered sideways out of the beam in water. This test showed that any loss of energy from the beam due to scattering is negligible.

The electrical method used for determining the amplitude of the received pulse permitted measurement over a much wider range than had previously been possible by other means.

The duration of the pulse was variable from 2 to 40 microsec. and the repetition frequency was 250 c./s. The received pulse was displayed after amplification on a time-base on a cathode ray tube, and an accurately adjustable set of timing marks was provided for velocity measurement if required. In order to measure the amplitude of the echo, a comparison signal was injected from a pulsed signal generator on the same frequency as the sound wave. A double-walled trough 5 ft. long contained the liquid, which was stirred vigorously; in the outer jacket, water was circulated rapidly from a thermostat. Above the trough was mounted an optical bench, fitted with a centimetre scale and sliding carriage to move the reflector. Independent fine adjustments could be made to the position of the crystal housing and reflector.



VARIATION OF α/f^2 WITH TEMPERATURE AND FREQUENCY

Measurements have now been made in water between 0° and 60° C. at 7·37, 15·0, 22·1, 36·9, 51·6 and 66·1 Mc./s. According to the theory of Stokes[5], the amplitude absorption coefficient α should be given by

$$\frac{8\pi^2\eta f^2}{3\rho v^3}.$$

If this formula holds, a plot of α/f^2 against f would be a straight line parallel to the f axis; the accompanying figure shows values of α/f^2 measured at six frequencies plotted against f for various temperatures of the water. It is seen that α/f^2 is constant within experimental error. The experimental value of α/f^2 is, however, larger than that given by the Stokes theory, as the following table shows:

Temperature	α/f^2 (sec.²/cm.) mean of observed values	α/f^2 (sec.²/cm.) calculated	$\frac{\alpha_{obs.}}{\alpha_{calc.}}$	Probable error (%)
0° C.	$56{\cdot}9 \times 10^{-17}$	$17{\cdot}09 \times 10^{-17}$	3·33	±0·6
5	44·1	13·40	3·29	±0·6
10	36·1	11·34	3·18	±0·86
15	29·6	9·59	3·09	±0·9
20	25·3	8·16	3·10	±1·35
30	19·1	6·15	3·10	±1·7
40	14·6	4·85	3·01	±0·5
50	11·99	3·98	3·01	±0·4
60	10·24	3·36	3·04	±0·8

The ratio of $\alpha_{obs.}$ to $\alpha_{calc.}$ is strikingly constant over a wide range of temperatures, although α itself changes considerably. The probable error of α/f^2, as judged from the variations about the straight lines drawn in the figure, does not exceed 1·7 per cent. It is noteworthy that the ratio $\alpha_{obs.}/\alpha_{calc.}$ shows a rise in the range 0–10° C., in which it is known that changes of structure occur in water.

(After some of the measurements had been made, a copy of the paper by Pellam and Galt[6] became available in which measurements with an essentially similar apparatus are described.)

Thermionic Properties of Thoria

It may be of interest to record our recent results on the thermionic properties of thoria coatings and of thoria in bulk. In the first experiments, a coating of thoria about 0·1 mm. thick was formed on a tantalum strip by spraying. The spraying suspension was made using an organic binder and solvent, as employed in standard techniques with barium–strontium carbonates. Direct current and pulsed emission were studied in a simple diode the anode of which could be water-cooled. The thoria surface temperature was estimated from pyrometer measurements assuming a spectral emissivity of 0·35 over the temperature range 1,800°–2,100° K.

Emission was at once available after outgassing, but rose by a factor of 3 or 4 during activation at temperatures from 2,000° to 2,100° K. Richardson plots were made of the saturated emission in the steady state, applying the formula $I = AT^2 \exp(-e\varphi/kT)$. These gave a mean value for the work function of 2·5(4) eV. in the D.C. experiments, and a mean value of A of 2·5, corresponding with an emission of 2·5 amp./cm.^{2} at 1,900° K. Higher saturated emissions were obtained under pulsed conditions, giving a work function of 2·6(2) eV. and a value of A of 7·5. Diodes were operated for 500 hours under D.C. conditions at temperatures from 1,950° to 2,050° K., taking currents of 3–7 amp./cm.^{2}. The emission fell in all cases, more rapidly at the higher temperatures, and at a rate which did not appear to depend on current density at a given temperature. In contrast with the behaviour of thoria coatings investigated by Weinreich[1], there was no rise in work function during operation, the whole of the decrease in emission corresponding with a decrease in value of A. The coatings remained white throughout, probably because the temperature was not raised above 2,200° K. A typical effect was a fall in saturated emission from 6·0 to 4·5 amp./cm.^{2} in 500 hours at 2,000° K.

Very similar results were obtained when cathodes were prepared by sintering a layer of tungsten powder on a tantalum strip, and painting the thoria coating into the sintered layer. This procedure is of American origin, and has been described, for example, in British Patent Specification No. 568962. The activation, work function and behaviour during prolonged D.C. operation were not distinguishable from the results with the sprayed coating; the mean value of A was, however, somewhat lower. This process avoids problems of adhesion which are encountered with the sprayed coatings, probably because there is little, if any, chemical reaction between tantalum and thoria below 2,200° K., the maximum temperature so far employed in cathode processing. With both types of cathode at 2,100° K., currents have been drawn of 10 amp./cm.^{2} under D.C. conditions and 30 amp./cm.^{2} under pulsed conditions, with none of the breakdown effects ('sparking' or 'flashing' between anode and cathode) which are commonly encountered with barium–strontium oxide coatings.

In the second series of experiments, a thoria cathode was made in the form of a tube by extrusion and sintering. The tube, of wall thickness 0·5 mm., was heated indirectly using a central tungsten wire heater-spiral. Emission was available at once after outgassing, and activation for a short time produced a stable emission which was studied under pulsed conditions. The work function was 2·5(5) eV. and the mean value of A 3·5, corresponding with a saturated pulsed emission of 3·6 amp./cm.^{2} at 1,900° K. The emission fell rather rapidly in the only diode so far operated over a long period, by about 40 per cent in 200 hours while drawing saturated pulsed emission at 1,930° K. In addition, a cathode of this type is sensitive to thermal shock, and cracks have developed after operation for periods varying from 20 to 250 hours.

The resistivity of the thoria as used in the tube cathodes was measured approximately, and found to be of the order of 30 ohm-cm. at 1,900° K. The resistance increased exponentially as temperature was lowered, with an activation energy of 1·1 eV. If the thoria coating had similar resistivity, in the first experiments, the resistance per cm.^{2} of the coating would be about 0·3 ohm at 1,900° K., which is about a tenth of the resistance of barium–strontium oxide at 800° C. This may explain the greater freedom from breakdown effects. In addition, there is reason to believe there is not a significant potential barrier at the metal-semiconductor boundary, so that the voltage drop is uniform through the coating and not concentrated near the boundary as in barium–strontium oxide coatings.

The watts radiated from a thoria surface at 1,900° K. were about 40 watts/cm.^{2}, corresponding with thermal emissivity 0·5(3). From this figure the emission efficiency in milliamperes per watt can be determined.

Use of the Cathode Ray Oscillograph for Studying the Near Infra-Red Solar Spectrum

AN apparatus has been developed in the Radiation Laboratory of the Meteorological Office at Poona for the measurement of absorption due to atmospheric water vapour in the near infra-red region of the solar spectrum by means of a cathode ray oscillograph. The working principle of this apparatus and the object for which it was developed are entirely different from those described by Daly and Sutherland and by King, Temple and Thompson[1], and it was developed independently of their work. A short paper describing it was read by me at the symposium on "Atmospheric Processes" held at the Royal Institute of Science, Bombay, under the auspices of the National Institute of Sciences of India in August 1946. This paper is at present in course of publication in a special issue of the *Transactions of the National Institute of Sciences of India*.

Work was started on this apparatus towards the end of January 1946. In the first model, which was ready by the middle of May 1946, an electrically maintained oscillating slit was used for scanning the image of the solar spectrum formed by a spectroscope. This slit was maintained in a steady state of oscillation by mounting it on a steel reed tuned to a frequency of 50 c./s., and was excited by means of an electromagnet supplied with 50 c./s. alternating current from the mains. The light passing through the slit was received by a cæsium oxide-on-silver photo-electric cell with a quartz envelope. The output of the photo-cell was amplified and applied to the vertical deflecting plates of a cathode ray tube. A 50-c./s. sinusoidal voltage obtained from the A.C. mains was fed to the horizontal plates of the cathode ray tube after passing it through a phase-shifting network. Thus the vertical displacement of the cathode ray spot was made dependent on the intensity of light passing through the slit; and the horizontal displacement was synchronized with the simple harmonic motion executed by the oscillating slit, and therefore it corresponded to the wave-length in the spectrum being scanned. Thus the cathode ray spot traced on the fluorescent screen a graph of light intensity against wave-length in the region of the spectrum being scanned by the oscillating slit.

Fig. 1 gives an idea of the performance of the apparatus in its present form, in which the oscillating slit has been replaced by a rotating disk with a number of identical slits. It shows the pattern produced on the cathode ray tube screen when the

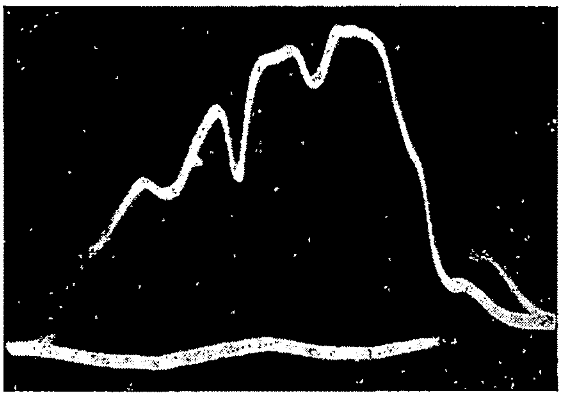

Fig. 1. ABSORPTION BANDS DUE TO WATER VAPOUR AND OXYGEN IN THE EARTH'S ATMOSPHERE

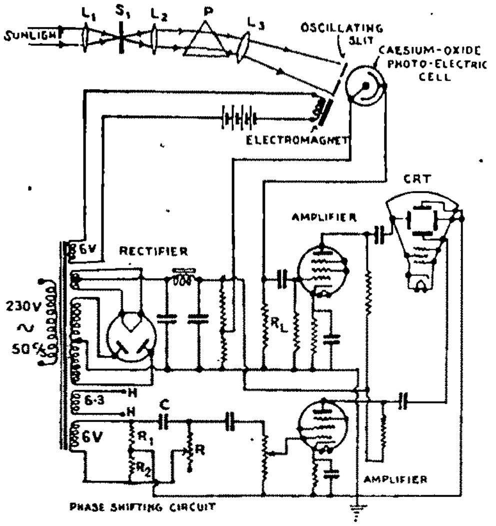

Fig. 2. CIRCUIT DIAGRAM OF CATHODE RAY TUBE SPECTROGRAPH

region between $0{\cdot}75\ \mu$ and $1{\cdot}3\ \mu$ in the near infra-red region of the solar spectrum was being scanned on a clear afternoon in January 1947. The absorption bands which can be seen in the photograph are, from left to right: oxygen band at $0{\cdot}76\ \mu$, ρ band (H_2O) at $0{\cdot}93\ \mu$ and φ band (H_2O) at $1{\cdot}13\ \mu$. Fig. 2 is a schematic circuit diagram of the apparatus.

This apparatus was developed for the rapid estimation of the total precipitable water vapour in the atmosphere. Its spectral range is limited to the visible and some portions of the near ultra-violet and near infra-red regions of the solar spectrum; the limiting factors being the transmission characteristics of the spectroscope optics, which are of glass, and the sensitivity of the photo-cells, which is restricted to the region between $0{\cdot}34\ \mu$ and $1{\cdot}5\ \mu$. A detailed account of the apparatus will appear elsewhere.

I wish to express my thanks to Dr. L. A. Ramdas, director of agricultural meteorology, Meteorology Department, Government of India, for guidance and for providing the necessary facilities for the work.

Interaction of Styrene with Magnesium Perchlorate and Other Salts

IN connexion with an investigation into the mechanism of Friedel-Crafts reactions involving styrene, we required a supply of this olefin of maximum possible dryness[1]. Before proceeding to drying by evaporation in an all-glass high-vacuum apparatus of the Stock type, a preliminary treatment with magnesium perchlorate ('Anhydrone') was given. We found, however, that polymerization was induced by this drying agent: in three weeks a highly viscous polymer was obtained.

This effect can be attributed to several mechanisms. It may be due to oxygen derived from the perchlorate, to perchloric acid generated hydrolytically, or to a co-ordinating action of the magnesium atom[2]. Organic complexes of magnesium perchlorate are known, as with dioxan, while styrene forms complexes with, for example, platinum chloride[3].

To test these views in a preliminary way styrene (*a*) dried over sodium sulphate and (*b*) saturated with water, was treated with magnesium perchlorate and magnesium chloride hexahydrate. The 'dry' perchlorate system showed 13 per cent polymerization in 48 hours: the 'wet' system 6 per cent; both as judged by estimation of residual monomer using a method based on the work of Williams[4] and Mulliken and Wakeman[5].

With magnesium chloride the effect is much slower, but the 'dry' olefin is converted to a viscous polymer in two months. 'Wet' styrene is largely unaffected in the same time. This last observation may be connected with the preferential formation of phenyl ethyl chloride, much as the reduced polymerization in the 'wet' perchlorate system may be due to hydroxylation—comparable with the acetylations induced by the Bertram-Walbaum and similar reagents[6].

We have further found that anhydrous calcium sulphate, which has been recommended for drying styrene, promotes polymerization after prolonged induction periods.

The above preliminary notes do not allow us to distinguish the mechanisms of polymerization involved, which we propose to elucidate by kinetic studies using a wide range of inorganic salts. In this way we hope to obtain information about the mode of action of free radical or electrophilic catalysts, and possibly uncover new examples of the latter type.

In the meantime, we wish to indicate that it is not safe to use magnesium perchlorate for the drying of styrene, and hence probably for drying other olefins. Further, it is probably not safe to leave this olefin in contact for more or less prolonged periods with salts which can exhibit co-ordination, or which can yield strong hydrogen acids by hydrolysis.

THE NATIONAL PHYSICAL LABORATORY

ANNUAL INSPECTION

REPRESENTATIVES of industrial organisations, university staffs and leading Government men of science were once again invited to inspect the work which is in progress during the National Physical Laboratory's 'open days', June 18–20. This second post-war exhibition followed the annual inspection by the Laboratory's General Board, of which the president of the Royal Society is chairman. Altogether, 264 exhibits were on show, illustrating the variety of work undertaken in the Laboratory's ten Divisions, and during the three days some two thousand people visited the Laboratory.

The National Physical Laboratory has grown steadily throughout its forty-six years of existence and now comprises sixteen large and a number of small buildings on a site of 60 acres. Until 1918, it was under the control of the Royal Society and, although since that date the Laboratory has been part of the then constituted Department of Scientific and Industrial Research, the Society still advises on the scientific aspects of the work.

The main aspects of the work of the Laboratory are the carrying out of research, including especially research required for the accurate determination of physical constants, the establishment and maintenance of precise standards of measurement, and the testing of instruments and materials. It also undertakes investigations of special problems on behalf of Government departments, for research associations representing various industries, and for technical institutions, industrial firms and others.

To describe any considerable number of exhibits in a short article such as this would be impossible, and mention will be made only of those items which are of outstanding general interest or which illustrate some interesting new development.

Of considerable interest to structural engineers is the research being carried out on the wind-induced oscillations of the proposed Severn suspension bridge, the centre span of which will be more than 3,000 ft. in length. The Tacoma Narrows Bridge in the United States, which collapsed in 1940 under torsional oscillation, had a centre span 2,800 ft. long. Dynamic scale models more than 80 ft. in length are being constructed for tests in a large wind tunnel specially built by the Ministry of Transport, and the structural components of these models were on view. In this tunnel, a special turntable will enable tests to be made on the model bridge at all horizontal angles of wind incidence, with wind speeds up to a maximum corresponding to 130 m.p.h. on full scale.

A more stable type of hot-wire anemometer for measuring wind speeds of less than 2 ft. per second has been recently developed at the Laboratory. In this instrument the heater wire and the thermocouple wires are carried in a twin-bore silica tube, which acts as a shield preventing deposition of extraneous matter on the wires. Considerable use has already been made of this instrument in various investigations, and it will find a ready application in such work as the ventilation of mines and buildings.

The Engineering Division had on show the results of work carried out in connexion with the adoption of a new standard thread-form by Great Britain, Canada and the United States. The major portion of this work had been completed in time for the Conference on the Unification of Engineering Standards in Ottawa in 1945, which decided upon the new form of thread to be recommended.

This Division of the Laboratory has given considerable help in the recent development of gas turbines. Work on the development of suitable bearings for use at the very high rotational speeds required, and the investigation of the fatigue and creep properties of various alloys, are of outstanding importance in this respect.

The tidal model work is now concerned with the Firth of Forth, and a model of the estuary has been constructed to a horizontal scale of 1 in 1,800. The main purpose of the investigation is the study of the deposition of silt in the approaches to Rosyth Dockyard, the dredging of which entails considerable expense. A model of the estuary of the River Wyre in Lancashire is under construction for the study of problems connected with the meanderings of the deep-water channel.

In the Electricity Division the determination of the velocity of electromagnetic waves is being made by measuring the frequency of electrical resonance of a hollow copper cylinder. This frequency depends only on the dimensions of the cylinder and the velocity of propagation of the waves, and an error of less than three hundred thousandths of a centimetre in the measurement of the dimensions allows an estimated accuracy of 9 km./s. in the determination of the velocity.

The High Voltage Laboratory had an exhibit illustrating the progress that has been made in the design and construction of an absolute voltmeter for very high voltages. This attracted-disk type of voltmeter will be housed in a compressed gas chamber, and with its development it is hoped to acquire experience of the properties of compressed gases as high-voltage dielectrics.

The quantitative study of the propagation of centimetre waves has required the development of suitable field-strength meters and standard radiators. The equipment displayed was designed for operation at wave-lengths of about 10 cm. and 3 cm., and consists essentially of antennæ of known gain (determined experimentally) relative to a half-wave-length dipole. In this sphere, a knowledge of the dielectric properties of the atmosphere and its constituents is needed for a full understanding of the propagation processes, and apparatus for the measurement of the reflexion and transmission coefficients of water at wave-lengths down to nine millimetres was also on view. The waves are reflected or transmitted through very thin plane sheets of water, and measurements on the effect of salt in solution have enabled a comparison to be made between the properties of sea- and fresh-water.

One of the interesting instruments on view was a photo-electric colorimeter employing an adjustable spectrum template. The three separate curves which measure and express the colour functions of the eye are not exactly the same for every individual, so that it has been necessary to provide an agreed set of average curves, which has been given the status of 'international standard observer'. The instrument consists of a photocell and the means to modify the response to that of the average observer. It has a wider application than the spectrophotometer, being capable of measuring not only absorption on coloured glasses or paper, but also illuminants such as discharge lamps and any colour illuminated by them. The accuracy with which the combination of photocell and colour filter gives the same results as the average eye is being investigated.

During the past year an entirely new section, on control mechanisms, has been added to the Metrology Division. This group has in hand the development of an electro-mechanical differential analyser. This machine will have twenty mechanical integrators and gear systems, interconnected by electrical remote control position servo-mechanisms, which will enable it to be used either as a whole or in sections permitting the simultaneous solving of several problems. A prototype model comprising two integrators was on view. The section is also concerned with the study of the principles of automatic control, and a pilot plant has been designed and constructed for this purpose. Oil is circulated through the plant and its temperature automatically controlled by closed-cycle systems employing the proportional, the floating (or integral) or the first derivative (or rate) method of control. Alternative control methods will also be investigated.

Ternary alloys of iron, nickel and chromium form the basis of numerous commercial alloys for use at service temperatures between 500° and 800° C. It is desirable—in many cases essential—that exposure to these high temperatures should not bring about any micro-structural changes which might be accompanied by a deterioration in the mechanical properties of the alloys. One such possible change is the formation of the brittle sigma phase in alloys of certain compositions when heated within the 500°–800° C. range, and the composition and temperature ranges over which this phase is precipitated in pure iron–nickel–chromium alloys is under investigation in the Metallurgy Division. One of several interesting points shown by this work is the extreme sluggishness of the process by which the sigma phase is formed in alloys containing about 20 per cent chromium, and the effect of increasing proportions of nickel on the sluggishness of the reaction. The indications are that alloys containing about 20 per cent of chromium and not less than 25 per cent of nickel will only attain true equilibrium after many months annealing at temperatures between 550° and 650° C.

Two new induction furnaces to be added to the equipment of the Division will be used in the first place to make alloys for studying the effects of alloying elements on the properties of pure iron. One furnace, designed to melt at least 50 lb. of iron in air, has already been installed, and a second furnace designed to melt 25 lb. of iron *in vacuo* is at present under construction.

The Ship Division, working in close collaboration with the principal shipbuilders and naval architects, is rendering very useful service in solving difficulties with regard to ship-form design, and models of all classes of ships, ranging from 30,000-ton liners to 45-ton launches, are tested in one or other of the two tanks. As a result of such tests, corrections to improve performance are made in the ship and, in many cases, a final check is carried out by staff during an actual voyage. Various pieces of apparatus used in these full-scale tests at sea were on view, and hull-form tests and propulsion experiments were being carried out in the tanks.

Modern requirements as regards comfort in buildings coupled with the necessity for fuel economy have led to an intensive study of the properties of walls, roofs and floors as regards resistance to heat flow. The Physics Division of the Laboratory displayed a wide range of equipment of this nature for dealing with, say, wall-sections weighing half a ton or thin sheeting materials such as wall-boards. Work is also carried out on wall-sections of cavity construction when the external surface is subjected to a daily cycle of radiation simulating conditions in the tropics. The uniform stream of radiation is supplied by a battery of incandescent lamps run at low filament-temperature and mounted in parabolic reflectors.

Since the War, fundamental work on acoustical measurement standards has been recommenced and the section concerned has been largely re-equipped. A new development on view this year was a large acoustic duct in which plane waves of sound are generated to serve for the standardization of microphones at low frequencies and for other experiments involving low-pitched sounds.

One of the sections of the Mathematics Division, that concerned with research into new computing methods and machines, is now engaged in the development of an automatic computing engine, the ACE, and a short lecture on electronic computing machines was given twice on each afternoon during the exhibition. A correlogram calculator constructed at the Laboratory was on view. This instrument is used for calculating serial correlation coefficients direct from a continuous graphical record, and uses three pairs of wheel and disk integrators linked together by an averaging motion.

THE CHEMICAL RESEARCH LABORATORY, TEDDINGTON

REPRESENTATIVES of all elements of the chemical community and including many distinguished foreign men of science have recently visited the Chemical Research Laboratory of the Department of Scientific and Industrial Research. These 'open days' coincided with the centenary celebrations of the Chemical Society, and a large party of fellows of the Society visited the Laboratory on July 17.

The Laboratory, founded in 1925 to provide a centre for the fundamental chemical research carried out in the Department of Scientific and Industrial Research, stands in the same grounds as the National Physical Laboratory. If it has not yet achieved the wide fame of its older and larger sister, it has shown a sturdy growth during its short life and, with the ending of its war-work, is entering upon a period of vigorous activity.

Since the end of hostilities, the Laboratory has been modernized and re-equipped. A large prefabricated building has been erected during the past few months and is in full use. The new building has been named after Stephen Hales, to commemorate this great experimental scientific worker who was, for more than fifty years, vicar of Teddington. Much of the existing building has been overhauled and modified to accommodate new techniques. These include micro-analysis, high-efficiency fractional distillation, spectrography and many more. The existing facilities in such major fields as the corrosion of metals, high-pressure reactions and plastics have been improved and extended.

The buildings contain sixty-five rooms of various sizes, of which eleven are specialist laboratories and three semi-scale laboratories. The Laboratory also has a drawing office, two workshops and a glass-working room manned by skilled staff who are engaged on the design, production and maintenance of the apparatus required in the various researches.

The programme of the Laboratory is undertaken on the advice of the Chemistry Research Board, the present chairman of which is Sir Norman Haworth. In addition to its own research programme, the Laboratory collaborates with other stations of the Department of Scientific and Industrial Research, including the National Physical Laboratory, the Fuel Research Station, the Forest Products Research Laboratory, etc., and carries out research for other Government departments. At present problems are under investigation for the Admiralty, the Ministry of Supply, the Board of Trade and the Agricultural Research Council.

The results of the Laboratory's researches are communicated to the Departments concerned, and to British chemical industry, as well as being published in the usual scientific journals. Special reports are also issued. General reviews have appeared for the period up to 1934; for 1934–37; and a review for the years 1938–46 is in the press.

The Laboratory, which is under the direction of Prof. R. P. Linstead, is organised in five main sections: corrosion of metals; inorganic; coal tar; high polymers and plastics. Provision is also made for exploratory and special work. Some past achievements of the Laboratory and a brief outline of its present work follow.

Corrosion, and particularly the rusting of iron and steel, cause losses of many millions of pounds per annum. This is not only a question of expense but also involves depletion of a natural resource which is not being renewed. It is, therefore, fitting that study of corrosion of metal and its prevention should have an important place in the programme of a laboratory established for the general benefit.

The formation of surface films by metals is a well-known phenomenon. The anodic oxidation of aluminium, discovered by this group of workers, involves a deliberate thickening of the film that forms naturally on this metal. A method of stripping films from metal, devised by Dr. U. R. Evans and improved at the Chemical Research Laboratory, has enabled the invisible films from metals such as stainless steel to be removed and analysed.

Corrosion of metals immersed in salt- or fresh-water is studied under static conditions, and when the samples are rotated at low and at high speeds. The rotor test devised at the Laboratory, although primarily designed for fundamental studies, found an immediate application on the outbreak of war in the evaluation of protective coatings for ships. Electrochemical methods now show great promise in determining the breakdown of paint films in immersed conditions. Atmospheric corrosion is especially important in relation to the present building programme, and attention is being given to the development of accelerated tests of painted surfaces. Some kinds of underground corrosion are due to the influence of bacteria. These micro-organisms are anaerobic and the damage occurs in clay or water-logged soil. The microbiological group of the Laboratory is at present concentrating on a study of these bacteria.

The experience gained in these researches on corrosion often enables the staff to assist in solving *ad hoc* problems by advice or investigation. Sometimes such work leads to useful discoveries. For example, war-work on anti-freeze materials led to the discovery of the remarkable inhibitive properties of sodium benzoate both in aqueous solution and when incorporated in wrapping materials.

Prior to the War, the Inorganic Section was investigating flue dusts and ashes as sources of semi-rare metals, but during the War special investigations were undertaken on behalf of the Ministry of Home Security. The successful outcome of one of these was the production of a fire foam agent from a cheap and indigenous source, as well as the provision of valuable fundamental information on the physical properties of foams. The possibility of making an entirely satisfactory carbon black from indigenous products was also demonstrated by this Section on a pilot-scale plant. Work on semi-rare metals has now been resumed on a broader basis. Some quantity of gallium metal and germanium halides have been prepared from indigenous material and are available for experimental work on possible useful applications.

Investigation of the composition of the tars produced by low-temperature carbonization of coal was started in 1925. The Coal Tar Section devised a scheme of separating groups of tar constituents by low-boiling solvents and dilute aqueous solutions avoiding the use of high temperatures. By this means comparative figures for tars from different sources were obtained and interesting products separated. One of these, a high-boiling tar-phenol fraction, proved very effective as a wetting agent in the mercerization of cotton, and was produced commercially as 'Shirlacrol'.

The Section is now concerned with the isolation and identification of tar constituents, using the most refined methods of separation and technique, such as high-efficiency fractionation combined with azeotropic distillation, of which a special study is being made. Allied to this is the determination of the physical and physico-chemical constants of pure coal-tar products by the most accurate methods available. Another objective is to find new uses for tar constituents or derivatives. For example, acenaphthene has been dehydrogenated to acenaphthylene, which, on polymerization or co-polymerization with styrene, yields polymers having interesting and promising characteristics.

Research on synthetic resins was one of the original topics in the programme of the Laboratory, and an outstanding contribution was the discovery of the ion-exchange resins, which has led to the establishment of a new branch of the plastics industry and to a new industrial technique. During the War, work was directed to immediate requirements, notably of the Ministry of Aircraft Production, such as the production of light-weight material using expanded resins, laminated boards and synthetic adhesives.

The High Polymer and Plastics Section is now engaged in fundamental studies of the relationship between chemical structure and the physical and physico-chemical properties of high polymers and plastics. Among the subjects under investigation are the development of improved synthetic glues and a fundamental study of ion-exchange resins with the view of producing a material of increased capacity or utility.

Pioneer work on high-pressure reactions, in the years following the founding of the Laboratory, resulted in the construction of apparatus and the discovery of catalysts by which aliphatic alcohols were formed from carbon monoxide and hydrogen, and aliphatic acids from alcohols and carbon monoxide. The high-pressure equipment then designed and constructed has proved a useful asset in the prosecution of the Laboratory's researches, and has frequently been made use of by industrial firms and other organisations. Other subjects under investigation are the production of various useful chemicals by catalytic hydrogenation and amination. A study is also being made of the preparation and polymerization of substances containing silicon. The Organic Intermediates Section also played a useful part in the development of the new synthetic fibre 'Terylene'.

Items of biological or agricultural interest which have been investigated in recent years or are still under investigation include the discovery of one drug of outstanding properties. This substance, 2 : 7-diamino-9-phenyl-10-methyl-phenanthridinium bromide, or C.R.L.1553, has been widely used against nagana, a trypanosome disease of cattle in Africa.

In order to make further use of Colonial products, research was carried out by the Microbiological Group of the Laboratory into the production of food yeast from molasses. Yeast production up to a pilot-plant stage was successfully achieved using a special strain of yeast, and the process is now in the course of full-scale production in Jamaica.

In collaboration with stations of the Agricultural Research Council, effective sheep dips and sprays containing D.D.T. have been formulated against blow-flies and sheep ticks, and special tar-acid emulsions were developed as a substitute for sulphuric acid in the destruction of potato haulm. The future policy of the Laboratory will be to extend these fruitful fields of discovery, to broaden the range of techniques available and to make the work of the Laboratory of the maximum possible value to British industry and to the chemical community as a whole.

NUTRITION IN NEWFOUNDLAND*

A STUDY of the history of Newfoundland should convince even the most hardened opponent of the need for Government planning. This island, a little larger than Ireland, a little smaller than England, has now some 320,000 inhabitants, mostly descendants of the original settlers who came from the British Isles. These settlers established themselves on the basis of one industry—cod-fishing—and sold their dry salt cod in many markets of the world. They bothered little about agriculture, and they soon depleted the stocks of game which once enriched the interior. This dependence on a single 'cash crop' meant that a bad year or a fall in the demand for their product not only spelt economic distress at the time but also resulted in a general downward trend from which the community was unable to extricate itself. In 1934 it was found necessary to suspend Dominion status.

As might be expected, this economic degradation showed in the health of the people : in a high infantile mortality-rate, in the number of still and premature births, in the incidence of tuberculosis, and in various clinical signs of malnutrition, including sporadic outbreaks of dry beriberi. In 1944 it was decided to copy the American plan of 'enriching' white flour with iron and some B-vitamins; but measures far more comprehensive than that are needed if Newfoundland's sickness is to be cured. Fortunately, there are now signs that this fact is recognized.

The nutrition workers who carried out the "Medical Survey of Nutrition in Newfoundland" in August 1944 were not content merely to report their clinical findings, but also submitted to the Commissioner for Public Health and Welfare specific recommendations for dealing with the situation, and they advised the setting up of a Council of Nutrition, "to include senior members representative of all the Departments concerned in the promotion of better nutrition of the people of the country". These recommendations were accepted by the Department of Public Health and Welfare as being "sound and essentially capable of being implemented", and a year later Dr. D. P. Cuthbertson, of the Medical Research Council, visited the island to advise on "the ways and means of approaching the programme in the field".

His report reviews the evidence compiled by the various surveys that had been made and discusses in detail the pros and cons of different methods of implementing the recommendations. The arguments range over such problems as 'enrichment' versus higher extraction rates for flour, 'uneconomic' local milk production versus imported processed milk, etc., and are therefore of interest to other territories besides Newfoundland.

From it all emerges, quite clearly, the fact that this programme for the attainment of good nutrition is going to make demands on agriculture, education, transport, industry and, not least, on the people themselves. Planning and direction are essential for, in Dr. Cuthbertson's own words, "Newfoundland . . . cannot, as at present constituted, exist as a sound economic unit capable of improving its social services so that there is freedom from want and disease". M. W. GRANT

QUANTUM ELECTRODYNAMICS

THE subject of quantum electrodynamics is extremely difficult, even for the case of a single electron. The usual method of solving the corresponding wave equation leads to divergent integrals. To avoid these, Prof. P. A. M. Dirac* uses the method of redundant variables. This does not abolish the difficulty, but presents it in a new form, which may be dealt with in two ways. The first of these needs only comparatively simple mathematics and is directly connected with an elegant general scheme, but unfortunately its wave functions apply only to a hypothetical world and so its physical interpretation is indirect. The second way has the advantage of a direct physical interpretation, but the mathematics is so complicated that it has not yet been solved even for what appears to be the simplest possible case. Both methods seem worth further study, failing the discovery of a third which would combine the advantages of both.

There is another fundamental problem in quantum electrodynamics. The classical theory disagrees with experiment, in that it allows a charged particle, in the absence of an ingoing field, to build up an acceleration and to radiate energy. This difficulty can be overcome in the classical theory by imposing the extra condition that the final acceleration must be zero. In quantum electrodynamics, the first of the new methods mentioned above does not seem to need any extra condition. On the other hand, the

* "Developments in Quantum Electrodynamics", Communications of the Dublin Institute for Advanced Studies A3, 1946.

second method does need an extra condition, but it is not at all clear what form it should take.

Theoretical physics is much more complicated than it appeared earlier in this century. About thirty years ago it seemed that all physical quantities were expressible in terms of tensors. The discovery of the wave equation of the spinning electron showed that we needed also spinors. Now Prof. Dirac shows that for quantum electrodynamics we need a new kind of quantity with components which transform linearly under Lorentz transformations, which he calls an 'expansor'. It has an enumerably infinite number of components.

FORTHCOMING EVENTS

Monday, July 28—Saturday, August 2

PHYSICAL SOCIETY, COLOUR GROUP (at Cambridge).—Conference on "Colour Vision".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER (temporary) IN PHILOSOPHY—The Secretary and Registrar, University College of North Wales, Bangor (August 1).

LECTURER IN APPLIED MECHANICS at the Royal Naval College, Greenwich—The Director, Education Department, Admiralty, London, S.W.1 (August 2).

SENIOR LECTURER IN ENGINEERING, and a LECTURER IN ENGINEERING OR ENGINEERING MATHEMATICS—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (August 2).

LECTURER IN ENGINEERING PHYSICS, to work in the Electrical Engineering Department of Queen Mary College and the Electro-Therapeutic Department of the London Hospital Medical College—The Registrar, Queen Mary College, Mile End Road, London, E.1 (August 2).

LECTURER IN ELECTRICAL ENGINEERING, a LECTURER IN AUTOMOBILE ENGINEERING, a LECTURER IN MECHANICAL ENGINEERING SUBJECTS, a WELDING AND SHEET METALWORK INSTRUCTOR, and a LECTURER IN BIOLOGY, at the Blackpool Technical College and School of Art—The Chief Education Officer, Education Offices, 3 Caunce Street, Blackpool (August 2).

ASSISTANT well qualified to teach MECHANICAL AND ELECTRICAL ENGINEERING SUBJECTS, at the Bolton Municipal Technical College—The Chief Education Officer, Education Offices, Nelson Square, Bolton (August 2).

LECTURER IN MECHANICAL ENGINEERING—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (August 2).

LECTURER IN ELECTRICAL ENGINEERING, and a LECTURER IN MECHANICAL ENGINEERING—The Principal, Paisley Technical College, Paisley (August 2).

PRINCIPAL OF THE TECHNICAL COLLEGE shortly to be established in Salisbury—The Director of Education, County Hall, Trowbridge, Wilts, endorsed 'Salisbury Technical College' (August 6).

JUNIOR PHYSICIST for research in connexion with medical applications of artificial radio-elements—The Director, Radiotherapeutic Research Unit, Hammersmith Hospital, Ducane Road, London, W.12 (August 7).

LECTURER IN ELECTRICAL ENGINEERING—The Secretary, The University, Edmund Street, Birmingham 3 (August 12).

RESEARCH CHEMIST at the National Gallery, London—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.512.47A (August 12).

SENIOR DIETITIANS and JUNIOR DIETITIANS to the Ministry of Food—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting G.248.47A (August 14).

JUNIOR PROFESSIONAL OFFICER (woman) IN THE BRANCH OF BOTANY AND PLANT PATHOLOGY, Department of Agriculture, Southern Rhodesia—The Official Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (August 15).

REGISTRAR OF RHODES UNIVERSITY COLLEGE, Grahamstown—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (August 15).

ASSISTANT VETERINARY INVESTIGATION OFFICER—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (August 15).

ASSISTANT PHYSICIST—The Secretary, University College Hospital, Gower Street, London, W.C.1 (August 15).

LECTURER IN PHARMACOLOGY—The Dean, Guy's Hospital Medical School, London, S.E.1 (August 15).

ASSISTANT (able to undertake instruction in Mathematics) IN THE DEPARTMENT OF MECHANICAL ENGINEERING, and an ASSISTANT (able to undertake instruction in Chemistry) IN THE DEPARTMENT OF GEOLOGY—The Secretary, School of Mines, Camborne (August 23).

ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF PHYSICS—The Registrar, University College, Cathays Park, Cardiff (August 23).

LECTURER (Grade IIc) IN THE DEPARTMENT OF ZOOLOGY—The Secretary, The University, Edmund Street, Birmingham 3 (August 25).

LECTURER IN MEDICINE—The Secretary, The University, Edmund Street, Birmingham 3 (August 31).

SENIOR SCIENTIFIC OFFICER in the Food Investigation organisation of the Department of Scientific and Industrial Research for work in a small laboratory at Smithfield, London, in association with the Low Temperature Research Station, Cambridge—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1943 (September 1).

SENIOR LECTURER IN GEOLOGY at the Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 1).

LECTURER IN GEOGRAPHY—The Secretary, Queen's University, Belfast (September 7).

CHAIR OF CIVIL ENGINEERING at the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 12).

PROFESSOR OF FINE ART (and Director of the Michaelis School of Fine Art); SENIOR LECTURERS IN (*a*) ZOOLOGY, (*b*) COMMERCE; LECTURERS IN (*a*) GEOGRAPHY (2), (*b*) PHYSICS, (*c*) PURE MATHEMATICS (2), (*d*) FRENCH; SUPERVISOR OF FIELD WORK (Social Science), in the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 15).

SENIOR RESEARCH FELLOW IN THE DEPARTMENT OF CHEMISTRY, University of Melbourne—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Melbourne, September 30).

SENIOR LECTURER IN MEDIÆVAL PHILOSOPHY—The Secretary of Faculties, University Registry, Oxford (October 1).

EXPERT IN TOBACCO GROWING (M.N.18166), AGRICULTURAL INSTRUCTOR IN TOBACCO GROWING (M.N.18167), for the tobacco monopoly of the Government of Iraq; TOBACCO BREEDING SPECIALIST (M.N. 18181), for the Directorate General of Agriculture, Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting appropriate Ref. No.

MECHANIC for experimental laboratory workshop in DEPARTMENT OF BIOCHEMISTRY, a TECHNICIAN IN THE DEPARTMENT OF ZOOLOGY, and a TECHNICIAN IN THE DEPARTMENT OF PHARMACOLOGY—The Establishment Officer, University College London, Gower Street, London, W.C.1.

ASSISTANT LECTURER IN GEOGRAPHY—The Secretary, Queen's University, Belfast.

HEAD OF THE PHYSICS DEPARTMENT—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan.

EXPERTS IN AGRONOMY (M.N.18175), PLANT PATHOLOGY (M.N. 18176), PLANT NUTRITION AND FERTILIZERS (M.N.18182), COTTON BREEDING (M.N.18177), SHEEP BREEDING (M.N.18178), FORAGE CROPS (M.N.18185), BIOMETRY (M.N.18186), PLANT BREEDING (M.N.18187), AGRICULTURAL EXTENSION AND DEMONSTRATION WORK (M.N.18179), for the Directorate General of Agriculture, Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting appropriate Ref. No.

LECTURER IN CHEMICAL ENGINEERING—The Head of the Department of Chemical Engineering and Applied Physical Chemistry, Imperial College of Science and Technology, South Kensington, London, S.W.7.

UNIVERSITY ASSISTANTSHIP IN THE DEPARTMENT OF BIOCHEMISTRY—The Secretary, The University, Edinburgh.

LECTURER IN BIOLOGY—The Registrar, Municipal College, Portsmouth.

ASSISTANT ENGINEER or TECHNICIAN FOR X-RAY DEPARTMENT, and a SENIOR ASSISTANT PHYSICIST—The Secretary, Mount Vernon Hospital and the Radium Institute, Northwood, Middx.

RESEARCH STATISTICIAN, an ASSISTANT STATISTICIAN, and a MATHEMATICAL COMPUTER—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

CHEMISTS IN THE JOINT DEPARTMENT OF CHEMISTRY, Malayan Union and Singapore—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

LECTURER IN ELECTRICAL ENGINEERING—The Clerk to the Governors, Heaton Technical Institute, 12 Chapel Street, Marlpool, Heanor, Nottingham.

LECTURER IN MINING at the Cannock Chase Mining College—The Director of Education (Dept. F.E.), County Education Offices, Stafford.

TRAINING OF SOCIAL WORKERS

NOTWITHSTANDING the fact that many social workers have succeeded without taking a course in social studies at a university, it is an outstanding feature of training for social work in Great Britain that it has been developed largely as a branch of university education. Partly because this incorporation in, or connexion with, a university distinguishes British training schemes from those in most European countries (where special schools for the training of social workers have been established), and to a lesser degree from those in the United States (where independent 'trade schools' and schools affiliated to a university exist side-by-side), it is too often forgotten that those university courses which are to-day designed to provide a theoretical basis for a social worker's practical work had their origins outside the universities. Soon after its foundation in 1869, the Charity Organisation Society organised for its workers courses enabling them to train as almoners; and, so long ago as 1893, the Women's University Settlement in Southwark initiated courses of lectures for social workers.

When the courses arranged at the Women's University Settlement led directly to the foundation of the School of Sociology—which became in 1913 the Social Science Department of the London School of Economics—the question of the relation between theory and practice was immediately raised. In the report of the proceedings of a conference convened in 1902 to discuss the creation of the School of Sociology, it is recorded that there was a wholesome prejudice against mixing theoretical and practical training. It was, the report continues, regarded as "imperative that the teaching of the Universities should be free from any suspicion of bias in controversial matters. Their function was to train students in the observation of facts and the construction of theory from such observation. . . . It would be improper for the University to attempt to direct studies in their practical work, but it might be done in University Extension lectures and by lecturers specially qualified going from place to place."

As long as the number of social workers remained small and their activities circumscribed, the integration of theoretical and practical training remained a secondary issue. With the recent increase in the number of social workers and the extension of their activities, the profession has, in the opinion of Miss Eileen L. Younghusband, "reached the point of development when neither general social science courses nor purely professional training fully meets its needs"; and her "Report on the Employment and Training of Social Workers"* is a plea for experiment in improving the quality of training. The weaknesses of present methods are all too obvious. Although university courses are generally of a high academic standard, they are unquestionably weak on the practical side; and much professional training—which might, if properly orientated, make good this deficiency—is so weighted as to make no significant contribution to the general body of knowledge and adds little to the student's education in basic principles.

---

* Carnegie United Kingdom Trust, Comely Park House, Dunfermline, Fife.

Although it certainly cannot be justified, the inadequacy of the part which is being played by many of the practical agencies engaged in training students can, in present circumstances, be explained. That those who carry out the day-to-day supervision of a student's work may themselves be trained or untrained may, or may not, be significant. What undoubtedly is significant is that they are not usually chosen because of some special aptitude for teaching students, that they have not normally been trained in teaching methods, and that they are compelled to regard the training of students as an incidental activity in the day's routine. It is therefore not surprising that Miss Younghusband finds "too little emphasis on the ethical and sociological issues involved in social work and on methods of helping people to help themselves. . . . Students are too often accepted because they are useful to the agency and not in order that a planned contribution may be made to the education of future social workers." It is, however, good to know that this critical attitude towards existing training schemes is shared by many social workers who are displaying "a tendency to stand back and look objectively at methods and a desire to seek guidance from their own best members and from outsiders in thinking out what they are trying to achieve".

That this discontent has not resulted in a spontaneous demand for the closer integration of theory and practice in university courses Miss Younghusband attributes to the clash of ideas which still exists regarding the function of a university and which was summarized so recently as 1944 in the two points of view expressed in the report of the McNair Committee on "Teachers and Youth Leaders". Those who favoured the joint board scheme declared: "If we may venture on a few general observations upon the functions of the Universities, we may say that in our opinion their main duty consists, and properly consists, in teaching basic subjects and in the advancement of knowledge". Opposed to them were the supporters of university schools of education who dissented strongly "from any sharp distinction between education and training, as though the one were the proper concern of the best institutions and teachers and the other were not". Rather did they express themselves as being concerned with training as "that part of the education of a student which emphasizes that he is preparing himself for a practical profession".

Nevertheless, as Miss Younghusband is well aware, the clash is academic rather than real. In providing courses for teachers and medical men the universities have long accepted the fact that they undertake vocational training. Where, perhaps, they have not accepted the responsibility thus incurred as fully as they might is in not always acknowledging the further fact that, having established such courses of training, they are logically committed to "testing the general suitability of those whom they admit, and whom they permit to complete the course and to emerge hall-marked with a professional qualification". Not the least of the merits of both the McNair and Goodenough Reports is their insistence on this point. As regards teachers, the former says that practical training in schools "should be so arranged that it enables a training institution to discover any students who are so clearly unsuited for teaching that they should be advised and, if necessary, required to abandon preparation for the profession"; and the latter, commenting on the selection of medical students, categorically insists that "however well-designed and conducted the training may be, it cannot produce successful results unless (1) in its organisation and conduct it allows for the full and active participation of the students, so that their education proceeds as much by their own efforts to learn as by their teachers' efforts to instil knowledge into them, and (2) the students are of suitable character and temperament and of an adequate standard of mental and physical fitness". Although Miss Younghusband quotes the passage from the McNair Report which postulates that "the personal suitability of applicants for entry into youth service is fundamental, and the institutions offering courses of training will keep continuously before them the need for devising the proper machinery of selection", she resists the easy—and obvious—conclusion that the quality of the training of social workers can be raised *merely* by increasing the vocational responsibility of the universities.

In this she is undoubtedly right. One result of the long separation—or, at best, partial integration—of theoretical and practical training is that the complexity of the problem has increased. There is, for example, no body of literature about the variety of human problems which make up the case or group worker's field of operation. Although, as she shrewdly remarks, it "could be continued indefinitely", Miss Younghusband's list illustrative of the need is in itself formidable: the highly sexed adolescent girl, the 'problem family', foster-home placement and adoption, 'unclubables', and the psychological factors involved in creating a community centre. Again, because it would be foolish to suppose that the closer integration of existing theory and practice would solve all training problems, there is the need for systematic inquiry and experiment. No attempt has yet been made to analyse the total content at which training courses should aim. Nor has it been decided what can most appropriately be acquired by lectures or discussion groups associated with lecture courses, or by working through illustrative cases, or by reading, work diaries kept by students, demonstrations, social surveys, visits of observation and actual practical work in different agencies. Miss Younghusband, who can speak with authority regarding the usefulness of the 'piecemeal and spasmodic' studies which are being undertaken, is emphatic that, if social work is to make any significant advance, a scheme designed both to promote research and to stimulate training must immediately be launched. Nor is she less emphatic that, as neither research will be promoted nor training stimulated "unless they are planned in relation to each other, and unless they are generously financed over a period of years until they are so well established as to be able to stand on their own feet", nothing less will suffice than the creation of a school of social work.

Few, if any, would dissent from the view that such a pioneer institution "could do far more to raise the whole standard of training than some relatively slight improvement in methods in the various social science departments". Nor will there be many to dispute that a school of social work should be designed for four purposes: (1) to undertake research; (2) to run courses in the theory and practice of social work, leading to a post-graduate diploma, for suitable graduate and other students; (3) to provide general and refresher courses for social workers, teachers, Civil servants and others whose profession requires a knowledge of social conditions; and (4) to provide facilities for study for social workers from other countries. More controversial, however, are some of the detailed proposals. Should the school be a separate school of a university, analogous to the Institute of Education in the University of London? Can the purposes of such a school be met by courses extending over a period of fifteen months? Should the number of students be limited to not more than a hundred? Should part-time and evening courses be made available?

In formulating her own ideas on these and other questions, and incorporating them in the report as a basis for further discussion, Miss Younghusband has performed a useful service. Unanswerable as her arguments in favour of the creation of a school of social work would seem to be, the immediate implementation of such a scheme is clearly impossible. As Mr. E. Salter Davies says in a foreword which he contributes to the report, so large a project is outside the competence of the Carnegie Trustees during the current quinquennium. Nevertheless, it has not been placed on one side. The examination of the practical possibilities of the scheme has already been entrusted to a committee composed partly of members of the Carnegie Trust and partly of persons actively engaged in social work. This is a step on which the Carnegie Trustees are deservedly to be congratulated; and it may confidently be predicted that, whatever this committee may recommend as the first practical step, the publication of this challenging and scholarly report will mark the end of an era in which the term 'social work' has been used much too loosely.

THE UNION OF MATHEMATICS AND PHYSICS

Methods of Mathematical Physics

By Dr. Harold Jeffreys and Dr. Bertha Swirles Jeffreys. Pp. ix+679. (Cambridge: At the University Press, 1946.) 63*s*. net.

A CENTURY ago or more, the study of astronomy, mechanics and physics was one of the most potent factors in the origination and development of new branches of pure mathematics. Men like Euler, Cauchy, Hamilton and Gauss were keenly interested both in natural philosophy and pure mathematics, and there was often a fruitful inter-connexion between the two parts of their work. With increasing specialization, the exponents of the two sciences tended to drift apart, and relatively few continued to cultivate both. The pure mathematicians went forward into regions whither few physicists of the time were able to follow them, and indeed most physicists regarded any such attempt as futile for their purposes.

The physicists, moreover, found an immense amount of valuable and interesting pioneer and development work in their laboratories, requiring little mathematical knowledge and skill. Even on the theoretical side, much of their work consisted of hypotheses of limited range, requiring only elementary mathematical development. A few men of exceptional insight, like Riemann, Maxwell, Boltzmann and, later, Einstein, were not content with this piecemeal science, and sought a wider synthesis. Maxwell ("Coll. Works", vol. 2, p. 419), criticizing the procedure current in the theoretical physics and chemistry of his time, wrote thus:

"In attempting . . . the explanation of chemical phenomena, we have to form an idea of the configuration and motion of a number of material systems, each of which is so small that it cannot be directly observed. We have, in fact, to determine, from the observed external actions of an unseen piece of machinery, its internal construction.

"The method which has been for the most part employed in conducting such enquiries is that of forming an hypothesis, and calculating what would happen if the hypothesis were true. If these results agree with the actual phenomena, the hypothesis is said to be verified, so long, at least, as some one else does not invent another hypothesis which agrees still better with the phenomena.

"The reason why so many of our physical theories have been built up by the method of hypotheses is that the speculators have not been provided with methods and terms sufficiently general to express the results of their induction in its early stages. They were thus compelled either to leave their ideas vague and therefore useless, or to present them in a form the details of which could be supplied only by the illegitimate use of the imagination."

Maxwell went on to indicate where and how a better way was to be found. "In the meantime the mathematicians, guided by that instinct which teaches them to store up for others the irrepressible secretions of their own minds, had developed with the utmost generality. . . ." His particular reference was to the general theory of dynamics, developed by Lagrange, Hamilton, Jacobi and others, which in our time has proved marvellously apt as a basis on which to build the new edifice of quantum mechanics. In the same way, the recondite geometrical and analytical researches of Riemann, Christoffel and others (in their day "to the [applied mathematicians] a stumbling block and to the [physicists] foolishness", to vary St. Paul's words) provided the tool needed by Einstein in developing his theory of general relativity and gravitation.

In this and other instances the history of modern physics confirms Maxwell's views. Great as are the achievements possible to the non-mathematical experimenter gifted with genius, the development of a true natural philosophy, a wide-embracing synthesis, requires the union of great mathematics with great physics.

To check the diverging drift of physics and mathematics into realms with different languages and interests, and to aid the physicists who realize the need for a combination of both, Courant and Hilbert as mathematicians produced in 1924 the first part of their famous work "Methoden der mathematischen Physik"; Part 2 followed in 1937, and together they form a great compendium and exposition of well-chosen domains of pure mathematics, valuable and relevant to physics.

Their example has now been followed by another such synthesis, worthy to bear comparison with that great predecessor—a British work, by two authors who are doing research and teaching mathematics in the University of Cambridge, and published in attractive form by its Press. Though consisting of one volume only, of manageable size, its content is about a third larger than that of Courant and Hilbert, with a word space of about 450,000 as against 350,000, though, of course, in each case much of this space is taken up by displayed formulæ.

A detailed comparison of the two books would be of great interest but cannot be undertaken here. Naturally, a good deal of ground is common to the two works; but there are also great differences of treatment and choice of material. In both works (and more particularly in the German one) the index is inferior in execution to the body of the work, and somewhat more effort spent upon it would have much helped the reader. But a comparison of the authors' names cited in the two indexes shows that the possession of Courant and Hilbert by no means renders superfluous that of '$2J$'—if one may modify and adapt, for the sake of a short and euphonious name of this book by Prof. and Mrs. Jeffreys, the familiar nomenclature (W^2) used by many mathematicians for "Modern Analysis" by Profs. Whittaker and Watson. It is safe to predict that '$2J$' will stand alongside 'W^2' as a treasured possession on the shelves of many physicists.

Among the distinctive and attractive features of '$2J$' are the initial chapters on the real variable, and Chapter 9 on numerical methods. Prof. Jeffreys' earlier monographs on operational methods and on Cartesian tensors are incorporated in other chapters. As in his volume "The Earth", the chapters are headed by quotations, the aptness of which is apparent in many cases. The chapters end, not, as in Courant and Hilbert, with references to further literature, but, in English fashion, with examples on which the reader can test his skill and his mastery of the text.

The book is well written, and the 'joins', if any, between the work of the two authors have not been detected by the reviewer. The severity of the subject-matter is occasionally lightened by touches showing the personality of the expositor. The book is a worthy addition to the great series of 'Cambridge Blues'.

FOLKLORE ON THE FARM

The Farmer's Friend or Wise Saws and Modern Instances

Being a Collection of Country Sayings. Compiled and commented upon by W. S. Mansfield. Pp. xiii+107. (Cambridge: At the University Press, 1947.) 6*s*. net.

PROVERBS, saws and trite sayings entered very largely into the conversation of countryfolk of old. In old-time Somerset, a couple of knowing heads would often wag over the stile, and two pairs of wise old eyes would peer through the lofty hedges at the snowy masses of fragrant apple-blooth, flushed with a faint pink Alpine glow. "A good cider year, please God!" "Please God!" comes the echo. "Thof a proud spring 'd' often get his comb cut!"

Mr. Mansfield's collection of sayings, most of which he has gathered directly from farmers, has been produced in an attractive format, with four charming and appropriate illustrations by John Hookham. In the first place we may comment on the numerous references to seasons of the year and even to characteristics of particular months. In the present age, when the bulk of our population no longer lives in close touch with Nature, many of these sayings will appear cryptic; but here Mr. Mansfield steps in with crisp explanations that cast light on the most recondite statements. For example, "If you see grass in January, Lock your grain in your granuary"; because premature growth is usually cut back by the return of cold weather. Again, "What grows in May should be eaten in May"; because the young and leafy May grass, with its high nutritive value, if under-grazed, will become woody and indigestible in June. Some of the older sayings of the months, no longer current, might be harder to interpret, as they often contain obsolete words. Thus, John Aubrey, the seventeenth-century antiquary, mentions a Wiltshire saying, "Sowlegrove sil lew" (February is seldom mild). "The vulgar in the West of England," he says, "doe call the moneth of March, *Lide*"—a word we find in the old rhyme: "Eate leeks in Lide, and ramsins in May, And all the year after physicians may play".

These obsolete words show the great age of some of the sayings, and illustrate the faithfulness of oral tradition among the English peasantry. Mr. Mansfield quotes, "An eldern stake and whitethorn ether, Will make a hedge to last for ever". Here, in 'ether' or 'edder', we have a word going back to the days of King Alfred: it refers to the twisted wands of a laid (or 'plushed') hedge. Eldern stakes, it used to be said in the West Country, will outlast in the ground an iron bar of the same size. Another western adage embalming a close knowledge of the characteristics of trees tells us that "A withy tree will buy a horse before an oak will buy a bridle and saddle": the willow is noteworthy for rapid growth.

In a short introduction of much charm, Mr. Kendon points out that modern agricultural research does not always bear out the truth of the adage; but more often than not these old sayings, preserving the accumulated experience of generations, are fundamentally sound. "Copper under heather, silver under gorse, gold under bracken": Mr. Mansfield shows that the experience of War Agricultural Committees has amply confirmed the truth of this picturesque saying. One must confess, however, that upon occasion there is an ambivalent quality in some of these expressions. Thus, "The master's foot is the best manure" inculcates the need for incessant watchfulness and industry on the land; but on the other hand, Jan Ridd tells us in "Lorna Doone" that—leastways, in Somerset and Devon—"God makes the wheat grow greener, While farmer be at his dinner".

A characteristic epitome of rural wit and wisdom is to be found in one of Mr. Mansfield's items which says that "He that buys land buys many stones, He that buys flesh buys many bones; He that buys eggs buys many shells, He that buys good ale buys nothing else". It is perhaps scarcely in keeping with old-time rustic thought to suppose, however, that the last sentence casts any reproach at the ale-bibber. The meaning seems rather to be that he who buys ale pays for no waste material, except perhaps for the last few drops in the cup which he sprinkles on the ground as a libation to a long-forgotten pagan deity commemorated in the traditional expression, "A drop for the wold Heark !"

Such sayings as we find in this intriguing collection range over the whole gamut of rural experience, and are by no means confined to observations on seasons, weather, birds, beasts, crops, trees, and the like. The human element, for example, is evident in such sayings as, "One boy is a boy, two boys are half a boy, and three boys are no boy at all"—a profound truth which holds in the laboratory as fully as in the field. Perhaps latter-day conditions will give rise to a similar saying in which the one, two and three boys are replaced by Greenwich time, summer time, and double summer time !

One final example, drawn from the reviewer's own experience, may be given as a masterpiece of terse expression. A Somerset farmer of the old school had been listening silently to a discussion on strikes and strikers. His opinion was asked. He removed his pipe, and as the adjacent cider-cup rose to its appointed place he let fall the memorable judgment : "Ah . . . Laziness idden wo'th much 'ithout 'tis well vollied !" JOHN READ

SCIENCE AND LIFE IN THE WORLD

Science and Life in the World

The George Westinghouse Centennial Forum, May 16, 17 and 18, 1946. (Whittlesey House Publication.) Vol. 1 : Science and Civilization ; The Future of Atomic Energy. Pp. ix+152. 12*s*. 6*d*. Vol. 2 : Transportation—a Measurement of Civilization ; Light, Life and Man. Pp. ix+236. 12*s*. 6*d*. Vol. 3 : A Challenge to the World. Pp. ix+198. 12*s*. 6*d*. (New York and London : McGraw-Hill Book Co., Inc., 1946.)

ON May 16, 17 and 18 of last year a significant gathering of men of science and leaders in the worlds of education and industry met at Pittsburgh to commemorate the hundredth anniversary of the birth of George Westinghouse, one of America's most renowned inventors and industrialists. Twenty-four prominent men in the field of science and technology were invited to participate in a notable symposium which summarized a great deal of our current scientific knowledge and pointed the way towards future research and development. A verbatim transcription of the addresses given on this occasion, together with illustrations including photographs of all the speakers, have been collected to make the three volumes reviewed here. As is to be expected, there is a wide variety of style, treatment and informative content in the different discourses.

The proceedings of the first day opened with an address on scientific ethics by Prof. A. V. Hill, foreign secretary of the Royal Society, who provided the link between the diverse matters which were considered after this. His thesis was that "the conditions of survival of man as a biological species and of his civilization involve a totally new factor in biology, the use of organised reason and accumulated knowledge. It was that which made the various civilizations possible and its perversions helped at intervals to bring them to an end." He is followed by Dr. Isaiah Bowman, the president of Johns Hopkins University, who speaks on the social composition of scientific power, and together with Dr. V. Bush, whose subject is "Planning in Science", provides a useful outline of the social aspects and possibilities of science. The latter part of the first volume is devoted to atomic energy.

Prof. J. R. Oppenheimer, who was in charge of the Los Alamos laboratory where the first atomic bombs were made, is rather inhibited by the demands of security, though he has some useful things to say and speaks with authority ; whereas Prof. E. Fermi, who constructed the first atomic pile, is less restrained and gives an account of the development of the pile, of which those at Hanford produce energy in amounts comparable with that of the largest hydro-electric plants. The applications of the new atomic discoveries to biology and medicine are dealt with by Dr. E. Chamberlain ; and Dr. Hugh S. Taylor of Princeton, who is perhaps best known in Britain for his catalytic phase-change method of separating heavy water, gives a short and simple statement of nuclear science in chemistry.

The first part of the second volume is concerned with the problems of transport, particularly from the American point of view. The scientific organisation of shipping, aviation and road transport is considered by various American experts in terms of economics, speed and convenience. The chapters should prove to be valuable to those who have to cope with the differing conditions in Great Britain and Europe ; but of most interest to the sociologist and layman is C. F. Kettering's paper on "The New American Way of Life" due to the development and popularization of the automobile. The book concludes with an excellent section entitled "Light, Life and Man". The various papers deal with biological warfare, photosynthesis, genetics with particular reference to artificial mutants and the recent work on moulds and enzymes, and Dr. Linus Pauling's investigations on molecular architecture in relation to biological reactions.

The third volume is an interesting mixture which shifts kaleidoscopically from one topic to another. There is a verbatim report of a broadcast brains trust, "Science, Salvation or Destroyer of Mankind", in which Dr. Urey has much to say. Also, we find an illustrated 'conducted tour' of the Buhl Planetarium and Institute of Popular Science at Pittsburgh. Accounts are also given of demonstrations in microbiology and crystallography using the optical apparatus at the same institution. There can be no doubt that good optical aids are an asset to the effective teaching of 'background' science. There follows a description of a visit to the Mellon Institute with its research work in plastics, petroleum and metallurgy. The volume also includes a number of short papers on the future of science as an aid to mankind, and Karl Compton's address on science "as an assurance against aggression and depression". The book ends fittingly with a short biography of George Westinghouse (1846–1914) by L. M. Stark. A detailed account is given of his invention of the air brake and the development of the turbo-alternator in the United States.

It is to be hoped that many more symposia on the broader social and ethical aspects of science will be held in various parts of the world, and that they will be reported as effectively as is done in these three admirably produced books. W. L. SUMNER

Calculating Machines

Recent and Prospective Developments and their Impact on Mathematical Physics; Inaugural Lecture. By Prof. D. R. Hartree. Pp. 40 + 2 plates. (Cambridge: At the University Press, 1947.) 2*s.* net.

THE rapid development of large-scale, high-speed calculating machines which has taken place in the United States in recent years is still not fully appreciated in Great Britain. These machines, in one form or another, are embodiments of Babbage's idea of an "analytical engine", and will undoubtedly have important effects both on numerical methods and on the attitude of the mathematical physicist to his problems. There is as yet no machine of this kind in Britain, though one is being planned at the National Physical Laboratory. The number of people from Great Britain who have seen the American machines is less than a dozen, and of these only one, Prof. D. R. Hartree, has actually worked the E.N.I.A.C., the electronic machine constructed at the University of Pennsylvania. This little book, therefore, has a particular importance. In this reprint of his inaugural lecture Prof. Hartree describes the E.N.I.A.C., and gives an account of the use he made of it in the solution of a set of non-linear differential equations with a two-point boundary problem. This gives him an opportunity to demonstrate vividly the remarkable speed of this type of machine, and to consider what features are desirable in such machines for general use in the field of mathematical physics.

The final section discusses the impact of these new developments on mathematical physics. The author suggests that not only will new mathematical developments be needed to devise new computing methods, but also that a new attitude to the problems of mathematical physics will be needed to make the best use of the facilities offered by this new type of equipment. In the author's own words, "It seems then quite possible that the facilities offered by these new calculating machines will at least make the formulation of physical problems in terms of integral equations and variation equations more familiar, and may in time wean us from our present tendency to regard a differential equation as the basic way of formulating the mathematics of physical problems".

Chemistry for our Times

By Elbert Cook Weaver and Dr. Laurence Standley Foster. Pp. xii+738. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 12*s.* 6*d.*

THE authors of this new elementary text-book aim at relating chemistry to everyday life, beginning with the immediate environment of the pupil and progressing from more to less familiar experiences. The basis is experimental, although modern theories, including very recent advances, receive adequate attention in their proper places. A special feature of the book is the wealth of illustration, all kinds of industrial plants being shown, as well as striking diagrams and very neat perspective drawings of apparatus. The text is well thought out, suitable revision being introduced from time to time, and the style is clear and attractive. Some organic chemistry is included. Problems are postponed until late, and the questions at the ends of the sections are aimed at stimulating thought rather than being tests of memory. Many anecdotes of the personalities of great discoverers are given, and the international character of science is well emphasized.

Although the book is elementary it is by no means superficial, a large amount of sound information being given in an interesting way; and care has been taken throughout to make the text intelligible and clear to any reader. We think any boy or girl beginning the study of chemistry would be interested by this book, and it could very usefully find a place in any school or public library. The authors are to be congratulated on the result of what must have been a difficult piece of work. There are very few matters which should be altered in future editions, but among these it may be suggested that the information about the explosive properties of mixtures of hydrogen and air should come before, rather than after, the description of experiments with this gas; the date of Black's discovery of fixed air is twice given as 1775 instead of 1756; and the god Aeschylus in Fig. 21–21 should surely be Aesculapius. The very moderate price of the book is most commendable. This is an excellent elementary text-book which brings the modern developments in discovery into relation with classical material in a very skilful way.

X-Rays in Research and Industry

By Dr. H. Hirst. Second edition. Pp. vii+124. (London: Chapman and Hall, Ltd., 1946.) 13*s.* 6*d.* net.

EXCEPT for minor corrections, this book is identical with the first edition published in Australia and reviewed in these columns a few years ago. The book provides a concise introduction to the technique of X-ray diffraction and radiography, and to its applications particularly in physical metallurgy. An outstanding feature is the detail with which the author describes the practical details required by the experimenter, and it is to the practically minded reader that the book will most appeal. Every technique is not covered; but sufficient of the standard techniques is given to allow any worker entering this field to make a useful beginning. Since the first edition, other books have appeared which treat the same field of X-rays and metallurgy in a much more comprehensive manner. The present book will be found helpful, however, as a very readable and succinct introduction to these larger treatises.

W. A. WOOD

Psycho-Analysis and its Derivatives

By Dr. H. Crichton-Miller. (Home University Library of Modern Knowledge, No. 164.) Second Edition. Pp. 272. (London, New York and Toronto: Oxford University Press, 1945.) 3*s.* 6*d.* net.

THIS small book, which has deservedly been a very popular one, gives a strong, straightforward and simple account of the theories of the different schools of psycho-analysis. The three chief schools of Freud, Jung and Adler are all discussed in detail, and Prinzhorn added to them. The writer considers Freud's the most intricate, Jung's the most profound, Adler's the most practical and Prinzhorn's the broadest. Adler's system, of course, owing to its simplicity, attracts a great deal of attention, possibly owing to the appeal of the so-called 'inferiority complex' and of the fact that Adler pays little attention to dreams. Prinzhorn's use of lay analysts almost without limit to their activities is open to criticism, but may, because of this, appeal to a large number of people. There is a brief note on developments along various lines, and some account of Stekel's work published in 1940.

ASPECTS OF THE BIOLOGICAL FUNCTION OF PHOSPHATE IN ENZYMATIC SYNTHESES*

By Dr. HERMAN M. KALCKAR

Department of Medical Physiology, University of Copenhagen

IT is just forty years ago since the late Sir Arthur Harden, together with Dr. W. J. Young, published the significant results of their studies of the effect of inorganic orthophosphate on cell-free sugar fermentation. Harden and Young[1] showed that phosphate is an essential component of this system, and this not merely by acting as a catalyst. They succeeded in showing that phosphate participates as a reactant in the process, that is, it is being esterified to sugar. One mole phosphate is esterified per mole glucose converted into alcohol and carbon dioxide. The phosphoric ester which accumulates was already identified by Harden and Young as fructose-1-6-diphosphate, later called the 'Harden–Young ester'. The chemical events taking place were summarized by Harden and Young in the following equation :

$$2 \text{ glucose} + 2 \text{ phosphate} = 1 \text{ hexosediphosphate} + 2 \text{ ethyl alcohol} + 2 \text{ carbon dioxide.}$$

Harden and Young's fundamental discoveries led to many other important studies such as Robison's and Embden's isolation of glucose monophosphates, Meyerhof and Lohmann's studies of glycolysis in muscle extracts and Lundsgaard's observations of the chemical events which accompany the alactacid muscle contraction.

These developments are familiar to investigators and students in this field. The purpose of the present survey is not to attempt a description of the historical development but rather to try to outline a picture of the present position in this field.

The problems to be discussed have been arranged in the following order :

(1) Generation of phosphate bond energy :

(*a*) from oxidation-reductions (formation of acylphosphates) ;

(*b*) from enol formation from dihydroxy structures (phosphopyruvate).

(2) Transfer of phosphate bond energy :

(*a*) reversible phosphate exchange (adenosine triphosphate-creatine-carboxyl) ;

(*b*) dephosphorylations (myosin adenosine triphosphatase) ;

(*c*) irreversible transphosphorylations (phosphorylation of hydroxy groups).

(3) Enzymatic exchange of aldehydephosphates with sugars and N-bases :

(*a*) polysaccharide formation (starch and glycogen from glucose-1-phosphate) ;

(*b*) dissaccharide formation (from glucose-1-phosphate) ;

(*c*) nucleoside formation (from ribose-1-phosphate and P-nucleic acid).

Such an arrangement is, of course, purely arbitrary, but it is hoped that it will facilitate the presentation of the problems to be discussed.

It is logical, for example, to start the discussion with a description of the characteristics of biological oxidation-reductions which, being reactions capable of releasing large amounts of energy, condition the occurrence of biological syntheses.

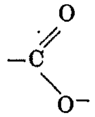
The first oxidation step in the breakdown of sugar is the oxidation of phosphotriose to phosphoglyceric acid, which is eventually converted into pyruvic acid. In fermentation, the latter is either reduced directly to lactic acid, which is the typical glycolysis, or reduced after decarboxylation, which is alcoholic fermentation. The conversion of phosphotriose to pyruvate involves two reactions which produce much energy. The first and most important of these steps is the oxidation of phosphoaldotriose to phosphoglyceric acid, the cozymase being the electron acceptor. The other reaction is the anhydride reaction by which the α-keto structure of pyruvic acid is formed from the dihydroxy structure of phosphoglyceric acid.

Phosphoglyceric acid, although poorer in energy than phosphotriose, is apparently endowed with an extra source of readily mobilized energy, namely, the possibility of converting the dihydroxy structure of this compound into the anhydride, pyruvic acid. Both the oxidation-reduction and the anhydride reaction are known to be coupled with the synthesis of the energy-rich phosphate bonds[2].

The oxidation of aldehydes to acids has hitherto been described according to Wieland's equation :

$$\text{aldehyde hydrate} \rightarrow \text{carboxylate} + 3H^+ + 2\varepsilon.$$

The release of free energy in this reaction is considerable, due to the formation of the highly stable carboxylate ion :



If one calculates the ΔF of the reaction aldotriose → glycerate, one finds that at pH 7 as much as 29,000 cal. are liberated per mole oxidized.

Calculation of ΔF of other aldehyde oxidations seems to give figures of the same order of magnitude, namely, between 28,000 and 30,000 cal. liberated per mole. This actually is a very large release of energy for a biological step-oxidation. The oxidation of lactate to pyruvate or of alcohol to aldehyde yields only some 8,000–9,000 cal. for example. It is natural to ask whether there is a pathway available to the living organism by which all the energy generated in aldehyde oxidations can be directed into something useful. At least two ways are known. One way, which is universally used, is through oxidation-reduction, that is, the energy of an oxidation is utilized to reduce something else ; this type of energetic coupling occurs in glycolysis.

In glycolysis, aldotriose plays the function of a hydrogen and electron donor, and pyruvate (the α-keto group) as hydrogen and electron acceptor forming lactate. Since the oxidation of lactate to pyruvate at pH 7 yields 8,300 cal., the same amount of energy is required in order to reduce pyruvate to lactate.

The oxidation reduction in glycolysis is not a one-step but a two-step reaction. The electrons from the triose are first transferred to cozymase, a substance which was also described first by Harden and Young in 1906. The chemical constitution of cozymase was clarified by Warburg and Christian in 1936[3] and shown to be a diphospho pyridine nucleotide in which the nitrogen of the pyridine participates in the acceptance of the electrons donated from the aldehyde group of the triose.

---

* A lecture delivered at University College, London, on July 5, 1946.

It is well known that the triose which donates the electrons in this enzymatic oxidation is not a free triose but a triosephosphate. However, it is important to bear in mind that the phosphate group referred to is located in the 3-position of the triose and therefore far from the site of the oxidation. Nevertheless, we ought to keep the existence of this phosphate group in mind, since it will be important in a later step-reaction. The replacement of triose by triosephosphate, thermodynamically speaking, makes little difference. However, the replacement of pyruvate by diphospho pyridine nucleotide as an electron acceptor makes some difference. The system*

$$DPN^+ \rightleftarrows DPHN$$

has a lower redox potential than the system

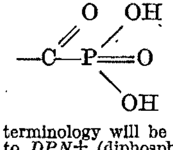
$$\text{pyruvate} \rightleftarrows \text{lactate}.$$

About 13,000 cal. are released when *DPHN* is oxidized to DPN^+ at *p*H 7. Consequently, the same amount of calories are required in reducing diphospho pyridine nucleotide to the reduced form. Thus, in the reaction

$$\text{phosphoglyceraldehyde} + DPN^+ \rightleftarrows \text{phosphoglycerate}^- + 2H^+ + DPHN,$$

13,000 cal. of the 29,000 cal. released by the aldehyde oxidation are being consumed for the reduction to the reduced cozymase. The reduced diphospho pyridine nucleotide formed can, of course, serve as a reducing system for numerous other compounds. The net free energy change at *p*H 7 of this oxidation-reduction is 16,000 cal.

A question of great significance is whether this still large amount of energy left over is available for synthetic processes. This question was attacked successfully by Needham and Green at Cambridge[4], and by Meyerhof and his group at Heidelberg[5]. These two groups have been able to show the existence of a coupling between the oxidation of triosephosphate by diphospho pyridine nucleotide and the phosphorylation of adenylic acid or adenosine diphosphate to adenosine triphosphate. Moreover, inorganic phosphate is a necessary component of this system and is consumed in the reaction. In order that phosphorylation shall proceed, oxidation is required; and the continuation of the latter reaction depends on the presence of phosphate acceptors. The two processes are therefore mutually dependent. The true nature of this interesting type of coupling has been clarified through some remarkable studies made by Warburg, Negelein and their co-workers[6,7]. These investigators succeeded in isolating a very peculiar ester, a carboxylphosphate, which is extremely labile and which is formed as the primary product in the enzymatic oxidation of phosphotriose. The discovery of this new type of phosphate ester made possible the first chemical formulation of a coupling between an oxidation and a biological synthesis based on enzyme experiments. According to this formulation, phosphate undergoes a sort of complex formation with aldehyde, and it is this complex which is oxidized, yielding a phosphorylated carboxyl group, a so-called acylphosphate.



The reaction can be expressed by the following equation:

$$\text{phosphoglyceraldehyde} + \text{phosphate} + DPN^+ \rightleftarrows \text{phospho-glyceryl-phosphate} + DPHN.$$

Warburg and Christian found that this reaction was readily reversed. They determined the equilibrium constant at *p*H 7·4 and 37°; from these data ΔF can be calculated to be between 800 and 1,000 cal. This means that as much as 15,000 cal. have been bound as chemical (or potential) energy since, as will be remembered, the oxidation of phosphotriose to phosphoglycerate, without inorganic phosphate as a participant, had $- \Delta F$ of 16,000 cal. The aldehyde phosphate complex is generally assumed to require only a smaller amount of energy and to take place spontaneously. The 15,000 cal. bound are apparently accumulated in the acylphosphate. This is further supported by the fact that the acyl compound, that is, phospho glycerylphosphate, is capable of phosphorylating adenosine diphosphate to adenosine triphosphate in the presence of a specific enzyme[8]. This reaction is an equilibrium which is far towards the side of adenosine triphosphate formation.

The bond energy of acylphosphate must be somewhat higher than the bond energy of a pyrophosphate linkage, which according to Lohmann's studies lies between 10,000 and 12,000 cal. per mole. Since the reaction between the acylphosphate and adenosine diphosphate can be reversed, it means that adenosine triphosphate is capable of phosphorylating a carboxylate group. From what was said previously, it will be understood that once the carboxyl group is phosphorylated it can readily undergo reduction to aldehyde through a labile aldehyde phosphate complex.

The old observation by Harden and Young that arsenate can replace phosphate as an activator in the cell-free fermentation and is active in minute amounts seems also to be explained by Warburg and Negelein's formulation. According to Warburg, arsenate is supposed to react with carbonyl groups like phosphate, and the only decisive difference is that the carboxyl arsenate formed by oxidation from the carbonyl complex undergoes a rapid spontaneous cleavage whereby inorganic arsenate is continuously regenerated. This spontaneous disintegration of the primary oxidation product would, of course, make the oxidation process irreversible, a fact which was actually observed by Warburg and Christian. Nevertheless, the coupling as such is supposed to exist also in the presence of arsenate and is only concealed by a secondary cleavage reaction. This example shows that the existence of numerous other important coupling reactions may be readily overlooked by reason of secondary disintegrations, non-enzymatic as well as enzymatic, of the primary reaction product formed.

Lipmann has discovered another acylphosphate which is being formed in biological oxidations, namely, acetyl phosphate[9]. This acyl compound is formed in the enzymatic oxidation of pyruvic acid:

$$\text{pyruvate} + \text{phosphate} \rightarrow \text{acetylphosphate} + 2H^+ + CO_2.$$

Acetylphosphate is also a powerful phosphate donor which is capable of phosphorylating adenosine diphosphate to the triphosphate. It has been found recently[10] that certain bacteria form butyryl phosphate in addition to acetylphosphate.

All the acylphosphates belong to the group having energy-rich phosphate bonds. This group includes adenyl-pyrophosphate (*ATP*, *ADP*), phosphocreatine and phospho-enol-pyruvate. The group of energy-rich esters is characterized by having a potential energy which exceeds that of ordinary phosphate esters many times. The ordinary ester bonds have a potential energy between 1,000 and 3,000 cal.; the energy-rich phosphate bonds are endowed with potential energies exceeding 10,000 cal. per mole.

---

* The Warburg–Haas terminology will be used, namely, oxidized cozymase is abbreviated to DPN^+ (diphospho pyridine nucleotide) to indicate the quaternary nitrogen, the reduced cozymase to *DPHN* (reduced diphospho pyridine nucleotide).

The appearance of a mesomeric configuration upon hydrolysis of the energy-rich phosphate esters might be an essential feature in the liberation of the large amount of energy. However, this aspect is a matter for a physical chemist to decide. It may be sufficient to state here that a large part of the oxidation energy released by oxidation of carbonyl groups in the presence of phosphate and the proper enzyme is stored as phosphate-bond energy. In the glycolysis in which pyruvate is the electron acceptor, an extraordinarily large proportion of the energy released in the oxido-reduction is accumulated as phosphate-bond energy.

I would like to mention another example in which one has strong reasons for suspecting an accumulation of energy in a phosphate bond. I am referring to Lipmann's investigations of the conversion of 2-phospho glyceric acid to free pyruvic acid[11,2]. The essential considerations in these theoretical studies were as follows: if free glyceric acid is converted into its anhydride, pyruvic acid, a great decrease in free energy is bound to occur. It can be calculated that about 12,500 cal. are released. Yet the conversion of 2-phosphoglycerate (an enzymatically formed isomer of 3-phosphoglycerate) into phospho-enol-pyruvate is accompanied by only a negligible amount of energy liberation. The 12,500 cal. of the anhydride reaction are stored and added to the ordinary phosphate ester-bond energy. The phospho-enol bond therefore releases altogether about 16,000 cal. upon hydrolysis. Correspondingly, phospho-enol-pyruvate is capable of phosphorylating adenosine diphosphate to adenosine triphosphate, and conversely adenosine triphosphate can phosphorylate pyruvate to phospho-enol-pyruvate. It has been found recently that the particular enzyme involved in this reaction is active only in the presence of potassium ions[12]. This potassium effect is apparently quite specific.

We have seen a few examples of how the breakdown of metabolites can bring about the synthesis of powerful phosphate bonds, especially adenosine triphosphate. The energy which is accumulated in adenosine triphosphate can be used either for specific purposes or transferred to other groups. It is a well-known fact that adenosine triphosphate can exchange reversibly its terminal phosphate group with amidines (creatine, arginine) just as it does with carboxyl groups. A peculiar enzymatic reaction is the phosphate dismutation which converts 2 moles of adenosine diphosphate into 1 mole of adenosine triphosphate and 1 mole of adenylic acid. This reaction is also readily reversed.

A great deal of interest has been directed towards the dephosphorylation of adenosine triphosphate in muscle, particularly after the observation by Engelhardt and Ljubimowa in 1939 that myosin, the contractile protein of muscle, contains large amounts of adenosine triphosphatase and that adenosine triphosphate itself exerts an effect on the mechanical properties of myosin. These observations were confirmed by Bailey and by Needham and co-workers. Recently, Szent-Györgyi and his co-workers[13] have made a number of interesting observations on the properties of myosin. Only a few of their main findings can be included in this account. Straub[14] found that the myosin hitherto described is a complex protein which can be separated into myosin proper, a protein which is crystallizable, and another protein called 'actin'. Dissociation of this complex, which is called 'acto-myosin', can be brought about by adenosine triphosphate and potassium ions in the proper concentrations. In 0·02 *M* potassium chloride and in the presence of magnesium ions, the addition of adenosine triphosphate causes a spectacular contraction of threads prepared from acto-myosin. The threads are also endowed with adenosine triphosphatase activity. If the potassium ion concentration is raised, the contracted thread relaxes again. We do not know how closely this experiment illustrates the normal contraction. It is of interest, however, to add that Buchthal and co-workers have found recently that pyrophosphate compounds cause contractions in muscle fibres and that adenosine triphosphate specifically brings about changes in the double refraction corresponding to restitution.

The role which the adenosine triphosphatase takes in muscular contraction is not clear as yet. Binkley[15] has suggested that there may be an interaction between phosphate groups and sulphydryl groups, yielding thioether linkages and free phosphate. This latter state should correspond to the contracted state. The above-mentioned dissociation between myosin and actin brought about by adenosine triphosphate might then be explained by a sort of phosphorolytic cleavage of thioether linkages, yielding adenosine diphosphate, a phospho protein and free SH groups. Such a type of reaction has been described by the same author in some *in vitro* experiments with liver extracts[16].

I do not think that it is an over-statement to say that a phosphorylation of the contractile protein of some sort or another is an alternative which deserves consideration in attempting to explain the transformation of chemical energy into mechanical. The relation of adenosine triphosphate and the triphosphatase activity to the mechanical function of myosin is undoubtedly a new and interesting approach in physiological chemistry.

The irreversible transphosphorylations by which adenosine triphosphate reacts with a number of hydroxy groups play a particularly important part in carbohydrate metabolism.

It may be added that a wide variety of hydroxy compounds are being phosphorylated enzymatically from adenosine triphosphate. Glycerol is phosphorylated to glycerophosphate in extracts of kidney cortex[17]. A bacterial enzyme is capable of catalysing the phosphorylation of one of the hydroxy groups in pyridoxal from adenosine triphosphate, yielding the phosphorylated pyridoxal compound, which is an active coenzyme[18].

The enzyme which catalyses the phosphorylation of monohexoses (glucose or fructose) to form hexose-monophosphates has been known for some time and called 'hexokinase', because it initiates carbohydrate metabolism, without regard to whether this means breakdown of hexoses or polysaccharide formation.

Cori and his co-workers[10] have recently made some interesting studies on muscle hexokinase. They found that this enzyme, if isolated from diabetic animals (alloxan-diabetic rats were used), is practically devoid of activity; but if a small amount of insulin was added the activity returned. The same phenomenon was encountered if they used rat muscle from animals injected with Houssay's diabetogenic hormone from the anterior pituitary. They were also able to demonstrate the inhibitory effect of the anterior pituitary factor on hexokinase *in vitro*. Also in this case the inhibition was overcome by insulin. The muscle preparations slowly destroy the anterior pituitary factor.

If an unknown substance, belonging to the amorphous fraction of the adrenal cortical extract, is added, the action of anterior pituitary factor is enhanced and prolonged, presumably due to protection from destruction. As will be seen, most of these *in vitro* effects reproduce fairly well the *in vivo* observation made by Houssay, C. N. H. Long, F. G. Young and others. Cori emphasizes that insulin probably also has a direct effect on hexokinase, corresponding to the observation showing that hypophysectomized animals are highly sensitive to insulin.

Muscle hexokinase is apparently a rather complicated enzyme system also in other respects. Two more activators seem to be required, namely, reduced cozymase (*DPHN*) and guanine.

The ester formed by hexokinase and adenosine triphosphate is glucose-6-phosphate or Robison ester, which can be converted into fructose-6-phosphate (Neuberg ester), phosphorylated once more, and undergo cleavage and breakdown. The glucose-6-phosphate can also be converted into glucose-1-phosphate, the so-called Cori ester. The isolation of this 1-ester is of special significance, since it gave the clue to the understanding of the mechanism of the biological formation of polysaccharide. The discovery of the enzymatic formation of α-glucose-1-phosphate from glycogen and phosphate by Cori and Cori in 1936[20] represents actually the first observation of a phosphorolytic reaction (that is, a reaction by which a linkage is broken by interaction of phosphate). The replacement of water by phosphate makes a great thermodynamical difference also in this case. The hydrolytic splitting of polysaccharides is practically irreversible, whereas the phosphorolytic splitting of this group of compounds is readily reversed.

It has been found that in order to start an enzymatic synthesis of polysaccharides the presence of minute amounts of glycogen is required prior to the reaction. Cori, Cori and Green[21] have found that the synthesis of polysaccharide from glucose-1-phosphate can actually be described as a lengthening of the existing maltosidic chains. The crystalline muscle phosphorylase builds up an amylose-like polysaccharide with long chains and no extra branches. The best priming substance for this enzyme is the highly branched glycogen, which contains a comparatively large number of terminal glucose molecules. The larger the amounts of glycogen added the faster is the reaction. This reaction can be formulated as follows:

glucose-1-phosphate + terminal glucose ⇄ terminal maltosidic linkage + phosphate.

It can be seen that the phosphate of the aldehyde group is replaced by a terminal glucose through a 1-4 linkage. Doudoroff[22] has found that certain bacteria synthesize sucrose in an analogous manner, that is, according to the equation:

glucose-1-phosphate + fructose ⇄ glucose-1-fructose + phosphate.

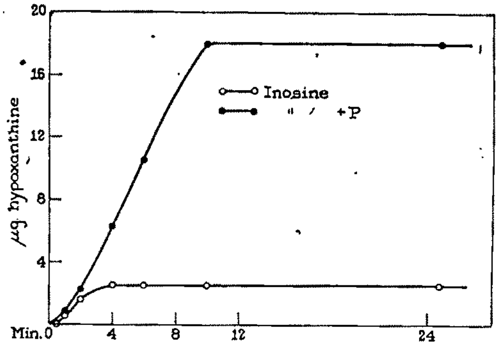


Fig. 1. EFFECT OF INORGANIC PHOSPHATE ON THE ENZYMATIC LIBERATION OF HYPOXANTHINE FROM HYPOXANTHINE-RIBOSIDE (INOSINE). ENZYME USED: NUCLEOSIDE PHOSPHORYLASE FRACTIONATED FROM RAT LIVER. THE AMOUNT OF PHOSPHATE (P) ADDED WAS 25 μGM. ORDINATE: μGM. HYPOXANTHINE LIBERATED. ABSCISSA: INCUBATION TIME IN MINUTES

On the other hand, the 1-6 polysaccharide dectran is synthesized according to a somewhat different although analogous scheme, described by the equation:

glucose-1-fructose + terminal glucose ⇄ 1-6-glucosidic linkage + fructose[23].

In this case fructose has the same role as phosphate. There is also a lævulan-synthesizing enzyme in which fructose is incorporated, and glucose takes the role of a phosphate group in replacing water and thus making the reaction reversible.

The Cori equation for glycoside synthesis apparently holds the key to a large number of important syntheses. The phosphorolytic reactions may also play a part in the biological synthesis of purine ribosides and related nucleosides. We have found recently[24] that nucleosidase, which liberates purines from nucleosides, was inactive in the absence of phosphate and could be re-activated by addition of comparatively small amounts of phosphates (see Fig. 1). This phenomenon was actually a confirmation of an earlier observation made by W. Klein in Freiburg[25]. Fig. 1 shows the great resemblance this phosphate effect bears to the Harden–Young effect and to the observations made by Cori and Doudoroff. It was natural, therefore, to assume that in this case also phosphate participated in the reaction and that a phosphate ester was formed. The search for this ester was somewhat hampered by the great lability of the new ester towards acids. The application of Lowry and Lopez's phosphate method[26] which operates at weakly acid reactions (around *p*H 4) greatly facilitated the further clarification of the enzymatic nucleoside fission. Thus one mole of phosphate was taken up in a highly labile bond for each mole of purine liberated. This relationship was found to be valid for hypoxanthine nucleosides and guanine nucleosides.

The new labile ester was isolated and analysed. It is non-reducing and contains one ribose per mole labile phosphorus. It is more acid-labile than phosphocreatine; fifty per cent of the new ester is broken down in 2·5 min. in Fiske and Subbarow's reagent at room temperature[26]. Upon acid hydrolysis, the ester becomes reducing, showing one aldose group per mole phosphate and ribose. We therefore have felt justified in calling it 'ribose-1-phosphate'. The more detailed chemical properties of this ester, particularly whether it is an α- or a β-ester, will have to be clarified by organic chemists. There is every reason to think that these problems will be solved in

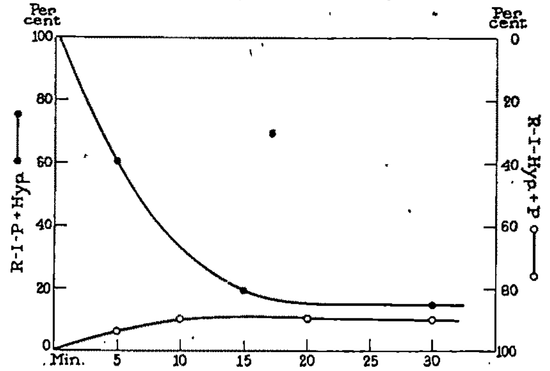

Fig. 2. EQUILIBRIUM BETWEEN A PURINE-RIBOSIDE (*R—I—Hyp*) AND THE PHOSPHO-RIBOSIDE (RIBOSE-1-PHOSPHATE, *R—I—P*). ENZYME: NUCLEOSIDE PHOSPHORYLASE FROM RAT LIVER. SUBSTRATE: EQUIMOLAR AMOUNTS OF *R—I—P* AND *Hyp* (LEFT ORDINATE) OR OF *R—I—Hyp* AND *P* (RIGHT ORDINATE). ORDINATES: PERCENTAGE OF INITIAL CONCENTRATIONS OF COMPONENTS REACTING. ABSCISSA: INCUBATION TIME IN MINUTES

the near future, by an application of the elegant technique developed recently in this field by Prof. A. R. Todd and Dr. R. J. Lythgoe.

If ribose-1-phosphate is incubated with hypoxanthine or guanine in the presence of a small amount of purified liver nucleosidase, an extensive synthesis of purine riboside takes place. The effect is particularly marked with hypoxanthine. Almost 80 per cent of the hypoxanthine is incorporated as a nucleoside. The equation for this type of reaction could be formulated as follows:

$$\text{ribose-1-phosphate} + \text{purine} \rightleftarrows \text{ribose-1-purine} + \text{phosphate.}$$

The equilibrium can be studied from both sides as illustrated in Fig. 2. The reaction is actually an enzymatic exchange between phosphate and purine. A very nearly related type of reaction has recently been described by Colowick and Price[27]. They found an enzyme in skeletal muscle which catalyses an exchange between guanine in ribonucleic acid and inorganic phosphate. The ribose-1-phosphate in the nucleic acid is even more acid-labile than that obtained from free nucleosides. Nevertheless, it has been possible to isolate small quantities of this 'deguanized' ribonucleic acid, which might also be called 'phospho-nucleic acid'. The demonstration of a guanine-phosphate cycle in nucleic acid may be important for an understanding of the biological function of nucleic acids.

I have occupied the major part of my space in dealing with *in vitro* studies and especially enzyme studies. The reason for this is mainly because these studies have taught us the intricate mechanism of the coupled oxidations and syntheses in which phosphate seems to have such an essential role. Before I finish this account, however, it seems natural to mention the ever-increasing number of studies of phosphate metabolism in various tissues *in vivo* using isotopic phosphate[28]. By means of this technique, it has been found that some of the most important phosphoric esters in muscle and liver are being rejuvenated with great rapidity[29,30]. Thus, after less than half an hour, more than fifty per cent of the phosphorus in adenosine triphosphate has been rejuvenated in the resting muscle, and only about five minutes are required to effect the same degree of rejuvenation of the adenylpyrophosphate present in liver[30]. These and many other observations bear witness to the occurrence of a very rapid uptake, transfer and liberation of phosphate in the living cells. The application of the same technique in the exploration of nucleic acid metabolism has been initiated recently by a number of investigators. These studies will undoubtedly produce many more interesting results, and perhaps be able to throw some light on the relationship between nucleic acid metabolism and cellular growth.

BRITISH FAMILIES EDUCATION SERVICE IN GERMANY

By F. J. DOWNS

Deputy Director, British Families Education Service

HISTORICALLY, the British Army has always maintained a goodly proportion of its strength overseas on service away from Britain. In peace (and within living memory during war, too) it has been the right of the regular soldier on certain conditions to have his wife and family with him on foreign service. For more than a hundred years, therefore, it has largely fallen to the Army to provide schools for British children overseas.

In Germany to-day elements of the three Services and the civilian Control Commission for Germany are serving in what is officially described by the Services as a 'home station'. It is therefore appropriate that arrangements for the British children who have joined their parents in Germany should follow the pattern of educational arrangements in the United Kingdom, and for this purpose a civilian organisation, the British Families Education Service, was established.

The British Families Education Service has taken as its mandate the implementation of the provisions of the Education Act, 1944, for all British children in Germany in so far as conditions here permit. Departmentally, its organisation is very similar to that of a local education authority in Great Britain. The B.F.E.S. policy-forming committee is regularly composed of high ranking officers representing the users of the school service (that is, the three Services and C.C.G.) and the director of the B.F.E.S., with occasional full representation by the Ministry of Education. This local "Education Committee" in Germany has become known as "The Board of Education, B.A.O.R.", and meets regularly each month to determine how best to interpret the Education Act, 1944, for British children in Germany to-day.

The implementation of agreed policy in the light of local conditions is co-ordinated by the British Families Education Service, at its headquarters offices at Herford, and effected by the regional education officers who are stationed with their staffs at each of the Control Commission Regions in the British Zone and in the British Sector, Berlin. These regional education officers, therefore, correspond to divisional education officers in Great Britain. All British teachers working with B.F.E.S. in Germany are from schools in Britain. Many have been seconded by their local education authorities at home for periods of from one to three years, and it is a widely held view that the breadth of experience the teachers will gain from the working conditions in Germany will at least partly reward the local education authorities at home for generously agreeing to secondment at a time when they are themselves in need of all their teachers. In addition to the British teachers, some Germans are employed part-time as nursery helpers and for some specialist subjects for which there are not sufficient British staff.

The H.Q. offices of the B.F.E.S. were established in Herford on September 24, 1946. Regional offices were opened and the first British teacher arrived in Germany during November 1946. Now after about nine months there are 220 teachers at work with about four thousand British children in about seventy different places. It is thus too soon to draw any but the most tentative conclusions from this first British local education authority overseas; but one or two points are worth noting.

The majority of the children arriving here from the United Kingdom are in the lower age group. Plans for the next stage of development anticipate a child population of some 10,000, which will break down as follows: 2,000 under 3 years of age; 2,000 between 3 and 5 years of age; 4,800 between 5 and 11 years of age; 1,200, 11 years of age and over.

Thus, numerically, the problem is about the same as for a small county at home; but in Germany to-day there are additional factors which make for complication in the organisation of education for the British children. Chief of these complications is that the children are unevenly scattered throughout 20,000 square miles of territory, with outliers in the Low Countries and Berlin. In some areas there are only three or four British children, in others three or four hundred.

It will therefore be apparent that if B.F.E.S. has had to establish school groups in about seventy different places the broad pattern will be for most of the British child concentrations to be between 10 and 150 strong, with a few larger concentrations of between 150–400. In such circumstances co-education becomes a practical necessity in order to economize in teachers, equipment, materials and buildings. It will be equally apparent that whereas the nursery, infant and junior groups are usually in teachable concentrations, the effect of uneven scatter on the smaller secondary population is, locally, to leave a large number of embarrassingly small 'senior tops' to the primary groups. This very inadequate solution is naturally only acceptable as an interim means of giving education on quasi-Dalton plan lines to children of secondary school age who have been brought to Germany in advance of arrangements being made for adequate secondary education.

So the B.F.E.S. has come to the conclusion that the only way that most of the British children over 11 years of age can receive satisfactory secondary education suitable for their age, ability and aptitude is by attending boarding schools. Accordingly, on July 1, 1947, the first publicly maintained co-educational secondary boarding school was opened at Wilhelmshaven in premises recently vacated by the Royal Navy.

The B.F.E.S. Prince Rupert (Secondary) Boarding School, Wilhelmshaven, will cater for 250 boys and girls. It is calculated that at least two further boarding schools of similar size (or rather larger) will be needed to provide education for those children of secondary age who can only be offered appropriate education in boarding schools. The demand undoubtedly exists among parents, more than four hundred having applied within a week of the first announcement about Wilhelmshaven; and further secondary schools will be established immediately B.F.E.S. is offered suitable buildings. It now seems likely that it may be possible to open a second large boarding school by Christmas. Apart from secondary education in boarding schools it has been found possible to establish a day secondary element of reasonable size in Hamburg, and necessary, because of its isolation, to have a similar secondary element in Berlin. Outside Wilhelmshaven, Hamburg and Berlin, B.F.E.S. teachers are only at the moment able to make *ad hoc* time-marking arrangements for children of secondary school age, and so the position will remain until further buildings are made available for secondary boarding schools.

Scattering has not complicated the establishment of primary school groups to anything like the extent that it has conditioned the basis of secondary provision. Primary groups are therefore being established to a more familiar pattern, though the school buildings on the whole are somewhat unexpected, and bear more resemblance to the conventional idea of 'private academies for young gentlefolk' charging expensive fees than to State schools charging nothing.

Scatter in most places has necessitated that British children attending day schools are collected in buses. Although distances are carefully watched, and the very young children are not allowed to travel, it is often inevitable at this stage that some children travel farther to school each day than is normally desirable. So, for economy of time and effort alone a school meals service would have been desirable in Germany to avoid a double midday journey, even were there not even stronger social training reasons for its institution. The B.F.E.S. school meals scheme for all school groups officially began early in May 1947 on a basis of container meals cooked in the nearest mess and transported to the school for the children to take their midday meal there. Later, as kitchens are prepared and equipped each school group will have its own cooking arrangements, as some already have.

B.F.E.S. has also instituted a school library service of several thousand volumes circulated in a hundred specially designed travelling showcases, which are used as portable lending libraries on arrival at the schools.

Now that B.F.E.S. is settling in, we are all very conscious that there is a long way to go and many problems to solve before the Education Act, 1944, is a complete reality for every British child in Germany. Books are still lamentably short, and starting as we are from scratch there are no past stocks on which to draw. There is certainly a lower limit below which book supplies should never fall; but anyone who has seen the improvisations and class teaching of B.F.E.S. teachers who can only, at the moment, be supplied with a small percentage of the books they want, may reach the conclusion that schools and school teachers have tended to put this lower limit too high. Like books, furniture and equipment is neither fully in position nor, in every case, to the requested specification of B.F.E.S.: each month, however, sees improvement.

School organisation is also seriously complicated by the movement of families, and here the Services are the chief offenders. One boy of nine, for example, had been in six different schools at various Army stations, while one B.F.E.S. school lost overnight twenty children from one regiment to receive in exchange twenty-five children from another. At the same time continual movement on any scale may well necessitate a degree of standardization of curriculum and text-books in order that the movement of children from one school to another can be accomplished as smoothly as possible. Similar standardization was forced upon Army schools, which have had continually to cope with the same problem.

It is far too early to estimate the psychological effect of residence in Germany on the British children. It is unhappily true that values are awry here to-day, and the British child may well get a sense of power which he is ill-adapted to assume. His few sweets, for example, have appreciable 'black market' purchasing power; the eagerness to do his bidding on the part of servants at home and in the families' clubs may breed in him an unnecessary arrogance; he may find, expediency being what it is, that a German boy may be cuffed by him without hitting back. Alternatively, he may find his sympathies overplayed and his outlook distorted by the many sights that can and have done both to adults working in Germany to-day.

Nevertheless, when all possible difficulties are appreciated a great deal remains on the credit side. The British schools in Germany can provide the German people with a very positive demonstration of British education in practice in their midst; and the behaviour of our children will be watched equally with the curriculum, as the behaviour of our occupation forces is at least as important as our formal laws and ordinances. For the British children themselves there is a profound potential for good in their attending a British school in Germany to-day. They will probably emerge bi-lingual, they will have wide opportunities for exploration, and they should emerge with a wider and more elastic attitude to their work, for their real joy in being at school is very apparent. Fundamentally, the chief determinant of whether bringing the children to Germany was a good or bad thing will be the quality of the British education provided here. This, in its turn, is a reflexion not merely of the printed word of the Education Act, but also of the skill and enthusiasm of the teachers in putting it into effect in the schools.

In its teachers, B.F.E.S. has been more than fortunate, and we all hope and believe that they themselves will benefit from the experience of a stay in Germany at least in proportion to the willing and excellent service they are giving the British children in Germany to-day.

NEWS and VIEWS

Hydraulic Research Organisation: Sir Claude Inglis, C.I.E.

With the appointment of Sir Claude Inglis as director of the new Hydraulic Research Organisation, the proposal to form a National Hydraulics Laboratory in Great Britain moves one more step towards realization. Sir Claude's work in India, where for many years he has been the leading exponent of the systematic use of models in the design of large civil engineering works, is known throughout the hydraulic laboratories of the world. He became director of the Central Irrigation and Hydrodynamic Research Station (now the Indian Waterways Experiment Station), Poona, in 1937, when it was taken over by the Government of India, and there, and in his previous capacity as superintendent engineer of the Research Division of the Bombay Irrigation Service, he has been responsible for the solution of a wide range of problems in river control: for example, the safeguarding, in 1934, of the Harding Bridge on the Ganges, where previously repairs alone had cost nearly a million pounds in two years, and the determination of the origin and remedy for the flooding of the Indus in 1942. Earlier, as assistant engineer or as executive engineer, Sir Claude was in charge of the construction of many works, including the building and remodelling of several canal systems in the Deccan. Such constructional experience should ensure that practical difficulties will be given full attention in the designs emanating from his Laboratory.

Perhaps the most important application of hydraulic work lies in the botanical and agricultural fields, and Sir Claude has had long experience in this, for in 1913 as executive engineer of the Poona Irrigation District he was reporting upon salt-saturation of soils arising from irrigation and evaporation; also at about that time he was responsible for introducing new and successful methods in connexion with land drainage and reclamation in the Deccan. His publications on hydraulics include such subjects as river meander, river training, scale effects and the use of distorted models, and he has been responsible for technical reports on very many irrigation, river and coastal works, many of which have been printed in the Annual Reports (Technical) of the Indian Waterways Experiment Station.

Metropolitan-Vickers Electrical Co., Ltd.: Dr. C. Dannatt, O.B.E.

Dr. C. Dannatt has been appointed chief electrical engineer of the Metropolitan-Vickers Electrical Co., Ltd., in succession to Mr. G. A. Juhlin, who has resigned, though retaining his connexion with the Company. Dr. Dannatt received his technical education under Prof. W. M. Thornton at Armstrong College, Newcastle, from which he graduated in electrical engineering in 1921. His studies were interrupted by the First World War. Dr. Dannatt went to Metropolitan-Vickers as a college apprentice in 1921 and afterwards joined the electrical and magnetic section of the Research Department, taking charge of the section in 1924. His activities have been mainly concerned with engineering investigations, and he is a recognized authority on electrical measurements especially in relation to magnetism and the behaviour of dielectrics. He is the principal author of a volume on "Electrical Power Transmission and Interconnection". In 1936 he was awarded the degree of D.Sc. by the University of Durham. Dr. Dannatt was appointed to the chair of electrical engineering in the University of Birmingham in August 1940; but at the request of the Admiralty he continued part-time activities with the Metropolitan-Vickers Co.; in the New Year Honours List of 1943 he was awarded the O.B.E. for contributions to naval gunnery. In 1944 he returned to Metropolitan-Vickers as assistant to the chief electrical engineer, and in the following year he was appointed deputy chief electrical engineer.

Mining and Metallurgy at Adelaide: Prof. E. C. R. Spooner

The Council of the University of Adelaide has appointed Dr. Edgar Clynton Ross Spooner to be professor of mining and metallurgy and director of the Bonython Laboratories at the South Australian School of Mines and Industries, in succession to Prof. H. W. Gartrell, who died two years ago. Prof. Spooner, who is thirty-nine, was born and received his undergraduate education in Tasmania, and was Tasmanian Rhodes Scholar in 1931. At Oxford he carried out research into electrode potential phenomena, for which he was awarded the degree of doctor of philosophy in 1936, and in 1946 the University of Tasmania conferred on him the degree of doctor of science for further research work in that field. On leaving Oxford, Prof. Spooner was for two years technical assistant to the works director of the National Smelting Company, Avonmouth, and then for seven years technical superintendent and works manager, and later assistant general manager, to the Magnesium Metal Corporation, Ltd., Swansea. Since December 1944 he has been technical adviser to S. G. Warburg and Company and director of research and development to Sutcliffe, Speakman and Company. In 1946 he was a member of the British Industrial Mission which investigated and reported on the active carbon industry of Germany.

Defence Scientific Advisory Committee, Australia

It was announced in *Nature* of June 28, p. 869, that Mr. A. P. Rowe had been appointed to take charge of a scientific advisory committee for defence in Australia. The United Kingdom Government has agreed to loan Mr. Rowe's services for a period of one year to the Australian Government for the purpose. Mr. Rowe will carry out the functions of defence scientific adviser in Australia and will establish a Defence Scientific Advisory Committee of which he will be chairman. The Committee will be constituted as follows: Defence Scientific Adviser, a representative of the Council for Scientific and Industrial Research, and one representative each of the following subjects—physics, chemistry, engineering and medicine; specialist Service and munitions representatives and scientific workers will be co-opted as required. The functions of this Committee will be to maintain a general survey of the scientific field and bring to the notice of the Defence Committee and the Chiefs of Staff Committee or through the Council of Defence to the Government, scientific developments having either direct or indirect bearing upon national defence.

British Hat and Allied Feltmakers Research Association: Dr. Thomas Barr

Dr. Thomas Barr has been appointed director of research to the British Hat and Allied Feltmakers Research Association. This newly formed Research Association will carry out investigations on problems provided by members of the felt-hat industry. Initially, the work of the Association will be carried out in accommodation provided by the Textile Industries Department of the University of Leeds. The location of the new research group at Leeds should prove an attraction and stimulus, since for the past quarter of a century Leeds has been one of the most active centres of both fundamental and applied research on animal fibres. Dr. Barr is at present in charge of a research section in the I.C.I. Dyestuffs Division, carrying out fundamental research work on textile processes involving the study of cellulose, natural and regenerated, the modification of wool and physiochemical studies of colloidal electrolytes such as synthetic detergents, etc.

'Sponsored' Research for Industry

In his address when opening the Fulmer Research Institute at Stoke Poges on July 2 (see p. 165), Sir Stafford Cripps said that the new Institute, which is constituted broadly on lines similar to the Mellon Institute in the United States, may well be the prototype of a kind of research organisation which could largely fill the gap between scientific research and its application in production processes, particularly for the smaller firms. There are, he said, three essential principles in any research institute which seeks to perform this general function for industry: its staff and equipment must be first class; the results of research sponsored by an individual firm must be retained by that firm, either as patents or as general technique and knowledge; and thirdly, the Institute should not be profit-making. Research and profit-making, he believes, do not mix well together, and although research should be carried out with reasonable economy, and elaborate equipment may not be necessary, it must be allowed ample time and a wide range of experimental failure. All these principles have been adopted in setting up the Fulmer Research Institute, and it has also been arranged for members of the staff of the sponsor firms to go and work in the Institute so as to be in a position to translate the results of the research readily into terms of factory processes. Sir Stafford Cripps also commended the Institute for the economy in scientific effort and said that the Government heartily welcomes this initiative as filling the gap which will be left even when joint research organisations have been set up as contemplated under the new Industrial Development and Organisation Act. In the first instance, the Fulmer Research Institute will concentrate upon metallurgical research, though other fields will be entered as the work develops.

University Teaching in Agriculture and Horticulture

In reply to a question asked in the House of Commons, the Minister of Agriculture, Mr. T. Williams, stated that the universities of Britain are sympathetic in principle with the proposals of the Committee on Higher Agricultural Education for raising the standard of degree courses in agriculture and horticulture, and have carefully noted the detailed suggestions in the report relating to the form and content of the courses. The Committee's comprehensive plan for the development and allocation of graduate courses is generally acceptable to the universities, some of which are hoping to introduce courses on the lines suggested this year or next. The main administrative recommendation of the Committee was that responsibility for grants in aid of higher agricultural and horticultural education at universities should be transferred from the Ministry of Agriculture to the University Grants Committee as from the beginning of the academic year 1947–48, on the understanding that the University Grants Committee would set up a specialist sub-committee to provide it with the necessary technical advice. Mr. Williams said that after consultation with the universities and with the Treasury he has accepted this recommendation, though he will naturally retain a close interest in the development of university teaching in agriculture and horticulture.

The constitution of the Agricultural Sub-Committee appointed by the University Grants Committee is as follows: Dr. A. E. Trueman (*chairman*), J. M. Caie, Prof. N. M. Comber, Sir Frank Engledow, Sir John Fryer, Sir Bryner Jones, Dr. Thomas Loveday, Prof. H. A. D. Neville, Dr. W. G. Ogg, Frank Rayns, Prof. E. K. Rideal, Sir Edward Salisbury and Dr. Norman Wright.

Foot-and-Mouth Disease Research Committee

The Minister of Agriculture and Fisheries has reconstituted the Foot-and-Mouth Disease Research Committee with the following membership: Dr. A. N. Drury (*chairman*), director of the Lister Institute of Preventive Medicine; Dr. C. H. Andrewes, of the scientific staff of the National Institute for Medical Research and a fellow of the Royal Society; Prof. S. P. Bedson, Goldsmiths' professor of bacteriology in the University of London at the London Hospital Medical College; Sir Daniel Cabot, chief veterinary officer of the Ministry of Agriculture and Fisheries; Mr. T. Dalling, director of the Ministry of Agriculture and Fisheries Veterinary Laboratory at Weybridge; Dr. R. E. Glover, director of the Laboratory Animals Bureau, Medical Research Council; Dr. Russell Greig, director of the Moredun Institute of the Animal Diseases Research Association, Edinburgh. Dr. I. A. Galloway, director of the Foot-and-Mouth Disease Research Station, and Mr. F. A. Eveleigh, of the Ministry of Agriculture, have been appointed secretaries to the Committee. The terms of reference of the Committee remain as follows: "To initiate, direct, and conduct investigations into foot-and-mouth disease either in this country or elsewhere, with a view to discovering means of rendering the invasions of the disease less harmful to agriculture".

Historical Library, Yale University School of Medicine

The sixth annual report of the Historical Library, Yale University School of Medicine, to which are appended the Chief Cataloguer's report and a list of the Monograph series issued by the Library, covering the year ended June 30, 1946, summarizes the principal points in the Library's plan for the next five years. This plan is based on the conviction that with the growing importance of science in the curricula of universities as well as in national life and international thought, greater stress must be placed upon the history of science and upon the humanistic values attached thereto. One of the primary aims of the new plan is to make the Historical Library the University's centre for historical studies in medicine and the allied sciences. For this purpose it is planned to augment Yale's holdings in medicine and allied sciences and, in co-operation with the University Library, to make them freely available throughout the University. The report directs special attention to some of the present holdings of the Library, such as those in the history of astronomy, geology, and early physics; and in particular the special collections in chemistry which, in addition to the works of Robert Boyle, John Mayow, Luigi Galvani, Alessandro Volta, Joseph Priestley and Antoine-Laurent Lavoisier, include all the writings of Sir Humphry Davy. The Library also has extensive Linnean holdings, and has concentrated heavily on the history of scientific societies in the seventeenth century. The new plan contemplates the creation of a chair of the history of medicine and science, and the extension of the Library's publications, both the Monograph series and the series of papers on bibliography and the history of medicine, as well as frequent exhibits of books, manuscripts and museum holdings.

During the year 1945–46, the Library staff formulated plans for a new periodical, the *Journal of the History of Medicine*. Distinguished visitors were received from many parts of the world, and space was assigned for editorial offices of *Cancer Research* and of the history of the U.S.A. Typhus Commission. The Library was actively associated during the year with the compilation of the Bibliography of Scientific, Medical and Technical Books, issued by a committee of the National Research Council, with an amplified translation of Dr. A. Castiglioni's "Adventures of the Mind", and with Mrs. M. L. Duran-Reynal's monograph on the history of quinine.

Demonstration Models of Physical Processes

Two interesting models, originally designed for exhibition in the Science Museum, London, have been described by Dr. F. A. Ward (*Proc. Phys. Soc.*, Jan. 1947). The first illustrates, by an optical analogy, the principle of the Bragg X-ray spectrometer, namely, that a monochromatic beam of X-rays will be reflected by a single crystal only when the crystal is set at a particular angle to the incident beam such that reflexions from successive sheets rich in atoms are in phase and so give an interference maximum. The incident beam is represented by a sheet of corrugated iron, and the crystal to be analysed by four glass plates mounted on a wooden rack. The observer looks into the glass plates, and rotates them until the virtual images of the crests of the corrugations appear to coalesce. The second model is a mechanical one illustrating the uranium chain reaction which has been utilized for the release of atomic energy. It consists of thirty units, each representing the nucleus of an atom of uranium 235 or plutonium. A unit consists of two portions held together by a catch which, when released, allows the two portions to fly apart, while at the same time projecting upwards three table-tennis balls representing neutrons. A single 'neutron' dropped on the catch of one of the units disintegrates this unit, and the three ejected 'neutrons' impinging on neighbouring units cause them to disintegrate, thus initiating the chain reaction. Both these models have been demonstrated at the Physical Society's science meetings, at the Society's Exhibition of Scientific Instruments and Apparatus, and also at the recent Royal Society conversazione, where they have aroused considerable interest.

Beit Memorial Fellowships for Medical Research

The Trustees of the Beit Memorial Fellowships for Medical Research have received with regret the resignations of Lord Rayleigh and Lord Macmillan of Aberfeldy; Sir Henry Dale and Lord du Parcq have been appointed to succeed them. The following elections have been made: *Fourth Year Fellowship* (£700 a year): F. Sanger, to study the structure of proteins with special reference to insulin (at the Department of Biochemistry, University of Cambridge). *Junior Fellowships* (normal value £600 a year): J. W. Lyttleton, to study the purification and subsequent physico-chemical characterization of proteins involved in the coagulation of blood (at the Lister Institute of Preventive Medicine, London); A. J. Marshall, to study the humoral and nervous control of the decidual reaction of the mammalian uterus (at the Department of Zoology and Comparative Anatomy, Oxford); L. Silberman, to study the community costs of tuberculosis in terms of public assistance and industrial outlay to patients and dependants, man-day wastage and social service provisions with special reference to the problem of reinstatement and revocation (at the University of Birmingham); Dr. G. Weber, to investigate the reactions and behaviour of physiologically important proteins (at the Sir William Dunn School of Biochemistry, University of Cambridge).

Institution of Electrical Engineers: Awards

The Council of the Institution of Electrical Engineers has made the following awards of premiums for papers read or accepted for publication during the session 1946–47. Group A: *Institution Premium:* Dr. H. G. Booker; *Kelvin Premium:* Dr. H. A. H. Boot and Prof. J. T. Randall; *John Hopkinson Premium:* H. A. Thomas. Group B: *Non-Section Premiums:* J. R. Mortlock and C. M. Dobson (Ayrton Premium), J. Hacking and J. D. Peattie (Llewellyn B. Atkinson Premium), C. H. Sparks (Extra Premium); *Installations Section Premium:* V. J. Francis and W. R. Stevens (Crompton Premium), F. Widnall and R. Newbound (Swan Premium), C. F. Freeman and H. V. Mather (Extra Premium); *Measurements Section Premiums:* W. Casson and Dr. F. H. Last (Silvanus Thompson Premium), Dr. F. M. Bruce (Mather Premium), Dr. A. L. Whiteley (Extra Premium), G. H. Farrington (Extra Premium), Dr. A. M. H. Arnold (Extra Premium); *Radio Section Premiums:* Dr. D. C. Espley, E. C. Cherry and M. M. Levy (Duddell Premium), C. Crampton (Extra Premium), W. Ross (Ambrose Fleming Premium), Dr. D. Gabor (Extra Premium), J. Bell, M. R. Gavin, Dr. E. G. James and G. W. Warre (Extra Premium), C. J. Banwell (Extra Premium) Dr. J. H. Fremlin, A. W. Gent, D. P. R. Petrie P. T. Wallis and Dr. S. G. Tomlin (Extra Premium) D. Cooke, Z. Jelonek, A. J. Oxford and E. Fitc (Extra Premium); *Transmission Section Premiums* G. T. Garwood (Sebastian de Ferranti Premium) T. R. P. Harrison (John Snell Premium), R. C. Cuff (Extra Premium). Group C: *Fahie Premium* E. P. G. Wright; *Paris Exhibition* (1881) *Premium* W. Fordham Cooper; *Webber Premium:* W. E. C Lampert; *Overseas Premium* (for senior members) T. S. Skillman.

Announcements

The First Class of the Order of Agriculture ha been conferred on Dr. W. Lawrence Balls, recentl chief cotton technologist of the Egyptian Ministr of Agriculture, by the King of Egypt on the occasio of his resignation from that country's service.

Prof. Arthur Holmes, regius professor of geolog in the University of Edinburgh, has been elected member of the Section of Natural Sciences of th Royal Netherlands Academy of Sciences.

Prof. Gustave Ribaud, professor of pyrometr in the University of Paris, has been elected a membe of the Section of General Physics of the Pari Academy of Sciences.

In connexion with the recent International Physiological Congress, the University of Oxford conferre the honorary degree of D.Sc. on the following: Pro S. A. S. Krogh, emeritus professor of zoophysiolog in the University of Copenhagen; Prof. A. Szent Györgyi, professor of biochemistry in the Universit of Szeged; Dr. H. S. Gasser, director of the Rockefeller Institute for Medical Research; Prof. B. A Houssay, recently professor of physiology in th University of Buenos Aires; and Dr. C. H. Bes professor and head of the Department of Physiolog University of Toronto.

Profs. A. C. Chibnall, G. R. Cameron and D. Brun have been appointed members of the Agricultur Research Council. Sir Frank Engledow and Pro James Gray retired from membership of the Counc on July 1 on the expiry of their terms of office.

Dr. C. L. F. Hunter has been appointed by P Chemicals, Ltd., as director of the Bray Researc Station, which is carrying out research into agricu tural problems.

Dr. Frans Verdoorn, managing editor *Chronica Botanica*, has been appointed an honorar staff member of the Government Botanic Garden Buitenzorg, Java, on the occasion of the hundred an thirtieth anniversary of the Garden on May 18, recognition of his work, during the war years, behalf of the scientific institutions of the Netherlan Indies.

The following appointments in the Colonial Servi have been announced: R. B. Blyth, to be supe intendent of agriculture, Nigeria; J. L. Congdo to be agricultural officer, Aden; H. W. Dougall, be agricultural chemist, Sierra Leone/Gambia; J. Waterston (plant pathologist, Bermuda), to be seni botanist, Nigeria; L. R. Langridge (senior surveyo Nigeria), to be divisional surveyor, Nigeria; E. Stanfeld (director of surveys, Jamaica), to be supe intendent, Crown Lands and Surveys, Hong Kon

LETTERS TO THE EDITORS

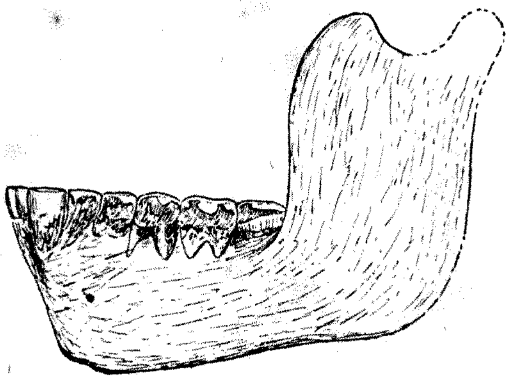
The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Jaw of the Male Sterkfontein Ape-man

On June 24, we blasted out at Sterkfontein, at a spot only about 8 ft. away from where we discovered the old female skull of *Plesianthropus*, the almost perfect lower jaw of a large male. The left mandible is complete except for the loss of the condyle and a little part of the margin of the angle. The whole symphysial region appears to be complete, while the right ramus is much broken and crushed. All the teeth of the left side are present, though worn.

The horizontal ramus is considerably larger than that of man but essentially similar. The ascending ramus is higher than in man, but otherwise not unlike that of the human jaw.

The front of the jaw is remarkably interesting. It does not slope rapidly backwards as in the living anthropoids but more downwards than backwards, giving an appearance not unlike that of the Heidelberg jaw. The front of the Sterkfontein jaw is narrower owing to the incisors being smaller. The symphysis, so far as can yet be seen, seems to agree fairly well with that of the Heidelberg jaw, and there appears to be no simian shelf.



True side view of mandible of male *Plesianthropus transvaalensis* (Broom). ½ Natural size

The molars are badly worn along their outer sides. The canine has its crown ground down quite flat and in line with the other teeth. Parts of the outer sides of the premolars are in the counter slab and will later be replaced

The molars and premolars are much larger than in the Heidelberg jaw, and the canine very much larger. The molars and premolars are much worn. In the case of the 1st and 2nd molars, the whole outer sides of the crowns are worn off; but on the inner side parts of the enamel cusps still remain.

The canine is the most interesting tooth of the jaw. We know the unworn lower canine crown in the male *Plesianthropus*. It is much larger than in man and has a well-developed and pointed main cusp and a small posterior cusp. In the female the upper canine we knew was worn down as in man, but in the male it was suspected that the lower canine passed in front of the upper as in the anthropoid apes. Now we find that the lower canine, while it may in the young animal pass up in front of the upper, is ground down, as age advances, by attrition with the upper, exactly as in man. The whole jaw is thus practically a human jaw.

This jaw is much too large to have fitted the elderly female skull recently discovered; and the skull that belonged to this jaw must have been remarkably large. If a restoration of the skull is made from the known female skull, but large enough to have fitted this jaw, it is seen that we have a skull that is nearly human.

The brain of the female skull was only about 450 c.c., but the male skull that belonged to this jaw must have had a brain of 600 c.c., or perhaps even 700 c.c.

Another interesting point is that on the lower part of the front of the jaw there is a little bony thickening which might be regarded as an incipient chin.

This jaw seems to us to be of considerable importance on the question of man's origin.

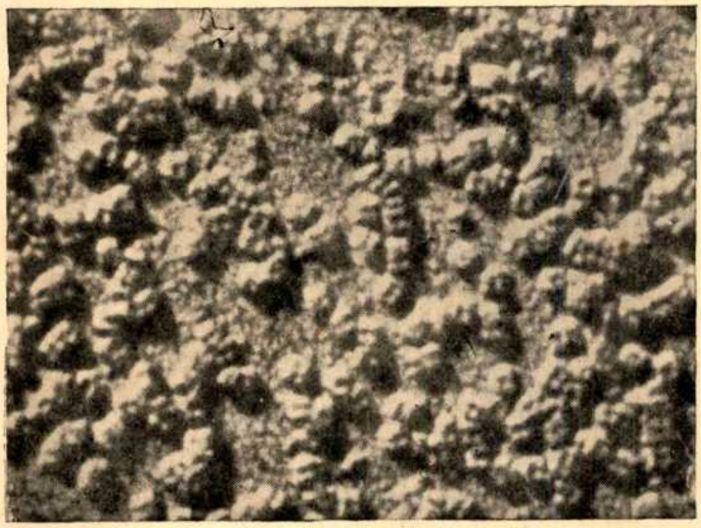
Shape of Hæmocyanin Molecules

In a previous communication[1] it was shown that the electron microscope can record the individual molecules in a solution of the respiratory protein from *Limulus polyphemus*. An unexplained feature of these photographs was the fact that the diameters of the molecular images were not uniform but showed considerable spread about a mean value. Hæmocyanins from several invertebrates have been under study in this laboratory partly to provide an interpretation of such apparent variation in molecular size and partly to see the reason for the reversible changes in molecular weight that have been established[2] through ultracentrifugal analysis.

Special attention has been given to the hæmocyanin from *Busycon canaliculatum*, living specimens of which were kindly provided by the Fish and Wild Life Service of the U.S. Department of the Interior. This hæmocyanin was selected because of its great molecular weight. Its published pH stability diagram records components with sedimentation constants of 130, 102, 61 and 13·5 Svedberg units, the two heavy components being absent at pH values above about 9. The principal component in freshly drawn 'blood' seems to be the one with the sedimentation constant 102 and an estimated molecular weight 6,800,000, but the existing data do not record the relative proportions of these components.

Electron micrographs have been made of fresh *Busycon* hæmocyanin and of this protein purified by ultracentrifugation. The pH of the solutions was established by adding minimal amounts of phosphate buffer and dialysing against distilled water to remove excess salt. Preparations for electron microscopy were made by putting these solutions and dialysates on the usual collodion-covered screens or by spreading them on glass slides for atomic replication. Shadowing was with gold at a 6–1 angle; photography was carried out with an R.C.A.-type *EMU* instrument.

Sufficiently diluted hæmocyanin near its natural pH yields an electron micrograph such as that reproduced herewith. Its single molecular particles are obviously uniform and possess a well-defined internal structure. Careful examination indicates that each large particle consists of rod-like sub-units stacked together, apparently in bundles of four. The sub-units are about three times as long as they are thick and have pairs, or all four, of their long axes parallel. This gives a cube-like composite particle of constant dimensions. At some places on the photograph the molecules are situated so that one looks down on the ends of four rods; at others the molecules are turned over so that two rods are seen lengthwise. At a few places one pair of rods seems to be rotated 90° with respect to the other, so that a tetrad shows the ends of two rods and the side view of another. The elongated sub-units can be discerned in all but the most alkaline preparations, but at higher pH the tendency to form tetrads has disappeared. At values of pH higher than about 10 the rods are replaced by very small particles which apparently result from their disintegration. It has not been possible to reconstitute larger molecules by adding acid to these strongly alkalinized solutions.



A GOLD-SHADOWED REPLICA OF A DILUTE SOLUTION OF HÆMOCYANIN FROM *Busycon canaliculatum* SPREAD ON A GLASS SURFACE. INDIVIDUAL MOLECULES ARE THE CUBE-LIKE OBJECTS ABOUT 3 MM. IN DIAMETER. × 77,000

A conspicuous and rather unexpected result of these experiments is the ease with which enough molecular damage can be done to interfere with the orderliness of this particle association. Removal of the last traces of salt by dialysis has brought about this measure of denaturation, and so has treatment with strong salt or purification by repeated sedimentation in the ultracentrifuge. The electron microscope offers an especially sensitive way of studying this type of minimal denaturation.

A detailed investigation is now under way of the molecular structures and stability ranges of fresh solutions of several typical hæmocyanins using both the electron microscope and the analytical ultracentrifuge. Preliminary results already demonstrate that in *Busycon* hæmocyanin undamaged molecules are uniform in size. The largest are regular groupings of smaller rod-shaped units, the associations and dissociations of which are responsible for the different molecular weights determined by the analytical ultracentrifuge.

Autotrophic Growth of Sulphate-Reducing Bacteria

Starkey and Wight[1] have reported reduction of sulphate to sulphide by *impure* cultures of sulphate-reducing bacteria growing in a strictly mineral medium containing sodium bicarbonate as sole carbon source, and in the presence of molecular hydrogen. It was not shown conclusively that pure cultures could grow in these autotrophic conditions.

At the time when Starkey and Wight's report became available in Great Britain (July, 1946) work was proceeding in this Laboratory on pure cultures of sulphate-reducing organisms in connexion with their role in anaerobic microbiological corrosion. Experiments were immediately initiated to determine whether these pure cultures are able to grow autotrophically. Pure cultures of four strains of *Vibrio desulphuricans*, isolated from different sources and exhibiting distinctive morphological characteristics, were subcultured into a medium containing sodium bicarbonate as sole source of carbon, ammonium chloride as nitrogenous nutrient, dipotassium hydrogen phosphate, calcium sulphate, magnesium sulphate, and a trace of ferrous salt. They were incubated at 30° C. in an anaerobic jar containing an atmosphere of hydrogen with 5 per cent carbon dioxide. At first, growth was obtained with one strain only; but successful attempts were made with the other three strains to acclimatize them to growth in media containing gradually decreasing quantities of lactate (the usual source of carbon for heterotrophic growth of sulphate-reducers). This procedure has now been found to be unnecessary, and growth has been obtained with all four strains by direct inoculation into the mineral medium. Growth is accompanied by reduction of sulphate to sulphide, which is clearly shown by precipitation of ferrous sulphide.

In final and conclusive experiments, stringent precautions were taken to ensure the absence of organic material. All glassware used in the preparation of media and for culture vessels was washed in chromic acid and finally in conductivity water. The cotton-wool plugs normally used in medium flasks and in culture test-tubes were replaced by loosely fitting beakers or tubes washed in chromic acid. Pipettes, instead of being wrapped in paper and dry sterilized, were placed inside large glass tubes and autoclaved. The medium was made up with 'Analar' chemicals and conductivity water. Good growth was obtained and has persisted through many subcultures, thus obviating any 'carry-over' effect of organic material from the original inoculant (2 drops). Numerous platings-out on various media incubated both aerobically and anaerobically have shown the cultures to be quite pure at all stages.

Stephenson and Stickland[2] have shown that resting non-proliferating cells of a strain of sulphate-reducing bacteria isolated by them contained an enzyme system capable of causing the reduction of sulphate to sulphide by means of molecular hydrogen. They found that the hydrogen absorbed was equivalent to the sulphate reduced and the hydrogen sulphide formed. Under their experimental conditions no growth occurred; but presumably the energy for autotrophic growth of the four strains is obtained by the oxidation of hydrogen brought about by the same or similar enzyme system. As one would expect, all attempts to cultivate the strains anaerobically in the mineral medium alone, in the absence of hydrogen, have failed. When, however, rods of carefully cleaned sterile mild steel are placed in the inoculated mineral medium and incubated at 30° C. in a closed jar containing alkaline pyrogallol for absorption of oxygen, definite growth occurs with reduction of sulphate to sulphide. As suggested by Starkey and Wight[1], who obtained similar results with contaminated cultures, it is probable that hydrogen is formed by reaction of the steel with water, and its oxidation supplies the energy for growth.

Similar autotrophic growth, both in mineral salt solution with hydrogen atmosphere and in mineral salt solution with immersed steel rod, has been obtained with a thermophilic strain of sulphate-reducers at 55° C.

It can therefore be concluded, in the light of Starkey and Wight's and our own experiments, that sulphate-reducing bacteria may be regarded as facultative autotrophs.

Gonads and Experimental Tuberculosis

Results, obtained to date, by different authors on the investigation of the influence of the sexual organs in experimental tuberculosis vary very much indeed. Mautner[1] and Bricker[2] admit that castration prolongs the life of the inoculated animals, whereas Brack and Gray[3] and Long and Vogt[4] deny such results. Vercesi and Merenda[5], Gray and Brack[6] and Long and Vogt[4] maintain that injection of œstrogens does not modify the course of experimental tuberculosis. Carnes and Biskind[7], who administered testosterone, reach the same conclusion. Most of these investigations have been carried out with very small groups of animals, and in others the results have been observed a few days after the inoculation; thus it has not been possible to define with precision the reaction of the animals to the tuberculous infection. Studies were carried out by us in the guinea pig to establish not only the type of pathological lesions, but also the survival-rate of the animals. These animals were grouped in the following manner: 20 castrated animals, 10 males and 10 females; 20 non-castrated females, which were injected intraperitoneally with 50 μgm. of œstradiol dipropionate three times a week; 20 non-castrated males, injected intraperitoneally with 250 μgm. of testosterone propionate three times a week; 20 control animals. All these animals were injected subcutaneously with 1 c.c. of an emulsion which contained 0·1 mgm. of tubercle bacilli of the human type.

The castrated guinea pigs showed an increased survival-rate as compared with the controls. During the course of the second month 10 per cent of the castrated animals had died, as compared to 30 per cent of the control group. In the fourth month 35 per cent of the castrated animals had died, as compared with 90 per cent of the controls. In the seventh month all the control group had died, as against only 60 per cent of the castrated group.

The pathological lesions found were characteristic of fibrocaseous involvement, whereas in the castrated animals there was a tendency towards lesions of the fibrous type. Animals injected with œstradiol or testosterone showed identical mortality figures with those of the control group; but the lesions were much more extensive and of the caseous type. The influence of the gonads on tuberculosis could be explained by the indirect action that the hypophysis exerts on the thyroid. Castration produces in the hypophysis specific reactions in the basophilic cells, which in turn would augment the stimulating action of the hypophysis on the thyroid. The fact that we have found[8] that castrated animals are hypersensitive to thyroxin seems to establish a basis for this reasoning. Contrary to what happens in castrated animals, the injections of œstrogen or testosterone show an inhibiting action on the hypophysis, which could induce a state of hypothyroidism.

Thus we find that the thyroid influences the course of experimental tuberculosis; thyroxin increases the survival-rate, whereas thyroidectomy has an opposing action.

Cultivation of the Erythrocytic Form of *Plasmodium gallinaceum* in Tissue Cultures of Embryonic Chicken Brain

In previous experiments a method was found for the cultivation of the exoerythrocytic form of *Plasmodium gallinaceum* in tissue cultures of embryonic chicken brain. It was found that proliferation of the parasites in tissue culture cells is very slow, and that the initial stages are difficult to observe *in vivo* and also in the stained cultures. Parasites were still found after 134 days of cultivation in tissue cultures.

On account of the slowness of the proliferation and the difficulty of observing the initial stages of the parasite, we repeated experiments on the cultivation of the form of the parasite found in the blood, which formerly were carried out without result, perhaps because insufficient time was given and also because of inability to recognize the early stages in the cells.

We cultivated embryonic chicken brain together with a drop of highly infected chicken blood, first, for some time in Carrel flasks, and passing later to the hanging drop method. With this technique and the better knowledge of the initial stages of the parasites in the cells, we have observed parasitized cells after three or four weeks of cultivation. The parasites in these cultures had the same form as those in cultures of the exoerythrocytic form.

Details and colour photomicrographs of the infected cells will be presented in the complete publication of this work, which will be sent to *Revista Brasileira de Biologia*.

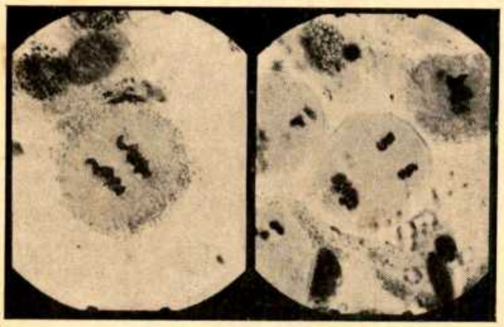
Chromosome Number and Behaviour in *Luzula purpurea* Link

IN the course of cytological investigations for the establishment of the chromosome atlas of the endemic flora of Portugal, we found in *Luzula purpurea* Link—a rare annual species only known from Portugal, Madeira and Canary Islands[1,2]—the diploid number $2n = 6$.

Besides their low number, the chromosomes of this species seem to be provided with two centromeres, one placed at each end of the chromosome. No median, sub-median or sub-terminal constriction could be distinguished either in mitotic or meiotic metaphases.

In anaphase figures both mitotic and meiotic the chromosomes take the shape of a **U** with their ends turned to the poles and not that of an inverted **V** as it normally occurs (see accompanying photographs).



This appears to be the first time such chromosome behaviour has been found in plants, and we think it may be related to what Toledo Piza[3] reported for the Brazilian scorpion *Tityus bayensis* Perty and for some Hemiptera[4]. Schrader[5], Hughes-Schrader and Ris[6], and Ris[7], working also with Hemiptera, found what they called "diffuse centromeres". This may be also the expression of a common behaviour.

A detailed description of the meiosis of *Luzula purpurea* will soon be published.

Mortality of *Aedes ægypti* Feeding on Rabbits Receiving Oral 'Gammexane'

LINDQUIST *et al.*[1] discovered the toxicity to bed bugs of the blood of rabbits fed on D.D.T., and de Meillon[2] has recently reported the action of 'Gammexane' in regard to mosquitoes. This communication describes a series of tests to elicit the minimum lethal dose of 'Gammexane' in similar circumstances, and the period during which the effect lasts.

The mosquitoes came from an *Aedes ægypti* colony, and were reared and stored in a constant-temperature room of 80°–85° F. in a humidity of 70 per cent. The tests were carried out in the same room; 72-hr. old unfed females were used. The 'Gammexane' was given in the form of a 5·5 per cent solution in rectified spirits, either in a capsule or more conveniently by pipette directly down the throat of the rabbit. Then, at different intervals, the mosquitoes were allowed to feed on the rabbits' ears, and those which fed were collected and stored in cages for 24 hr., when the dead were counted. Unfed specimens were discarded. Prior to the administration of the 'Gammexane', a control group of mosquitoes were fed on the animal, and the mortality was observed after 24 hr.

Two series of tests were conducted, the first to ascertain the minimum lethal dose during the first seven hours and at 24 hr., and the second to observe for how many days the insecticidal effect persisted. The results are shown in Tables 1 and 2 respectively.

TABLE 1. LETHAL ACTION OF 'GAMMEXANE' DURING FIRST 24 HR.

Dose of 'Gammexane'* (mgm. per kgm.)	Control		Hours after administration of 'Gammexane'				
	Number fed	Number alive after 24 hr.	1½	3	5	7	24
			Numbers fed and deaths after 24 hr.				
40	10	9	2:2	6:6	6:6	4:4	1:1

15	10	10	6:6	5:5	—	—	—	—

* 'Gammexane' = γ isomer.

The minimum lethal insecticidal dose appeared to be between 25 and 30 mgm. of 'Gammexane' per kgm. of rabbit, though even dosages of 15 mgm. gave a partial mortality. The figures suggest that the concentration of 'Gammexane' in the blood rises for 24 hr.; thus, with the lower dosages, mosquito mortality is incomplete at first, whereas if the insects are fed later in the 24 hr. all may die.

The persistence of the lethal action after a single dose varies according to the amount of 'Gammexane' administered. The maximum period for a complete kill was four days following a dose of 40 mgm. With lower amounts, the effect lasted only two days. The lethal action disappeared rapidly at the conclusion of these periods of complete mortality.

The final reading of deaths was always taken after 24 hr.; as a rule, most of the mosquitoes were 'down' three hours after feeding.

It is doubtful if the dosage could be increased much beyond 40 mgm. per kgm., for even with that amount several of the rabbits died in convulsions.

The number of mosquitoes used in the tests was rather small, chiefly because the insects showed a reluctance to feed on an animal treated with 'Gammexane'. Very often 50 had to be used in order to get 10 to take enough blood for a test, whereas with a normal rabbit practically all would feed.

The amount of blood imbibed by an *Aedes ægypti* was determined by weighing specimens on a torsion balance before and after feeding. The average weight of 30 unfed 72-hr. old females was 2·04 mgm. (± 0·3 mgm.); after feeding on a rabbit treated with 'Gammexane' the weight was 4·56 mgm. (20 specimens), representing a gain of 2·52 mgm. of insecticidal blood. On a normal rabbit the mosquitoes gorge more fully, and the average gain of weight with them was 4·16 mgm.

These results rather indicate that, so far as *Aedes ægypti* mosquitoes are concerned, the method has little practical application; first, because the effect lasts only for four days, and secondly, because the mosquitoes apparently dislike feeding on an animal treated with 'Gammexane'. The action of the insecticide, however, is powerful and is 100 per cent effective while it lasts.

I have pleasure in thanking my assistant, Mr. J. C. Pyefinch, for much practical help in carrying out the tests.

Frenkel's Views on the Origin of Terrestrial Magnetism

J. Frenkel has recently put forward[1] a theory of the origin of terrestrial magnetism that depends on the field being maintained by the electric currents induced in the liquid metallic core of the earth by the thermal convection of the material of the core.

Theories that ascribe the earth's magnetic field to motions in the core are attractive as, so far as is known, they provide the only possibility of explaining changes in times of the order of a century. Unfortunately, Frenkel's argument appears to contain faults which invalidate it.

Frenkel notes that free convection would occur in the core if the thermal gradient exceeded the adiabatic gradient, and shows that the rate of heat generation required (about 10^{-7} erg./cm.^{3}/sec.) is much below that produced by the radioactivity of surface rocks. However, the iron core model postulated is more appropriately to be compared in composition with iron meteorites than with surface rocks. Six iron meteorites analysed for uranium and thorium by Paneth[2] give an average heat generation of $4{\cdot}2 \times 10^{-8}$ erg./cm.^{3}/sec., which is not quite so much as Frenkel requires. This, however, is a minor point, as the theoretical value is subject to great uncertainty, and the experimental results are of doubtful relevance.

Frenkel assumes that the convective motion will be in paths of a size comparable with the radius of the core, and shows that if the viscosity is taken as 0·01 gm./cm.sec., velocities comparable with that of light will be generated. He concludes from this that viscosity is not able to control the convection currents and maintain reasonable velocities, and that the control must be by a dynamo action, of the kind suggested by Larmor. The system is supposed to approximate to an ideal thermodynamic engine for changing heat energy into electric currents. In fact, the Reynolds' number of the motion considered is about 10^6, and turbulent motion would certainly ensue, increasing the velocity gradients and enabling viscosity to control the motion. The viscosity assumed may well be too low, but if it is increased to obtain stability for the large-scale motion, the possibilities of energy dissipation in this motion will be increased. The hydrodynamic theory of a convecting core would repay detailed investigation.

No reference is made by Frenkel to Cowling's demonstration[3] that self-maintenance of a steady magnetic field by fluid motions with axial symmetry is impossible. Unless some way can be found of avoiding this theorem, all theories of the kind considered by Frenkel seem necessarily to fail in spite of their other attractions.

Relation Between the Intensity of Solar Radiation on 175 Mc./s. and 80 Mc./s.

In a previous communication[1] we described some experiments on electromagnetic radiation emitted from the sun on a frequency of 175 Mc./s. In the present note we give some results, obtained during the period December 1946–April 1947, of observations in which the same technique has been used to obtain simultaneous records of the intensity of solar radiation on the two frequencies of 175 Mc./s. and 80 Mc./s.

During periods of increased activity the radiation is characterized by the presence of short-lived 'bursts' of radiation having an intensity up to five times the mean value, and lasting from one to twenty seconds. An examination of the records shows that there is apparently no correlation between the times of occurrence of bursts of this type on the two frequencies. A section of a typical record is shown in Fig. 1. (The alteration of mean intensity recorded in this figure is due to the use of a pair of aerials as explained earlier[1].)

At times, however, very much larger bursts occur, having intensities as great as 20 or even 100 times

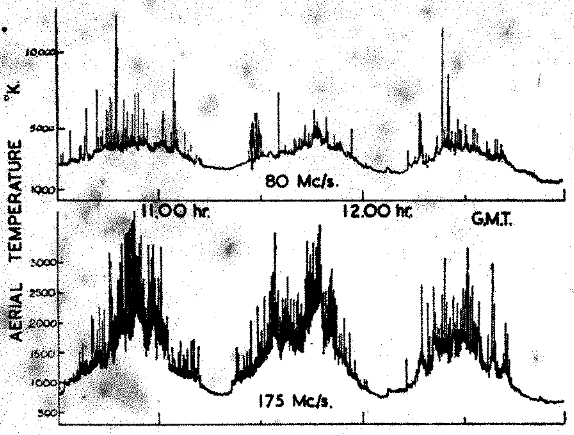

Fig. 1. SOLAR RADIATION, JANUARY 22, 1947

the mean value, and these may persist for many minutes. These larger bursts are usually observed on both frequencies, and many are accompanied by other evidence of solar activity, such as the observation of solar flares, or radio fade-outs.

The production of such short-lived bursts of high intensity is presumably due to a temporarily increased effective temperature of the source. The lack of coincidence between bursts observed on the two frequencies, therefore, suggests that radiation on these two frequencies originates in different regions, and that only during periods of great activity are both regions affected by the same sudden disturbance.

In addition to these short-lived bursts of radiation, the day-to-day variation of the intensity on the two frequencies has been investigated. The mean value during the four midday hours of each day has been plotted, for the period December 14–April 22, in Fig. 2. The intensities are expressed in terms of the equivalent temperature of a black-body source subtending an angle of ½°.

It can be seen that, while these curves show some evidence for variations with a period of 27 days (as would be expected from the movement of an active area across the sun's disk), there are other large-amplitude fluctuations of an apparently random nature.

In Fig. 3, the ratio of the equivalent temperatures of the source (T_{80}/T_{175}) has been plotted, and it is interesting to note that while the range of fluctuations is still of the order 4 : 1, it is considerably less than the range of fluctuations of the equivalent temperature on either frequency. This suggests that the day-to-day variations of intensity on the two frequencies are to some extent related.

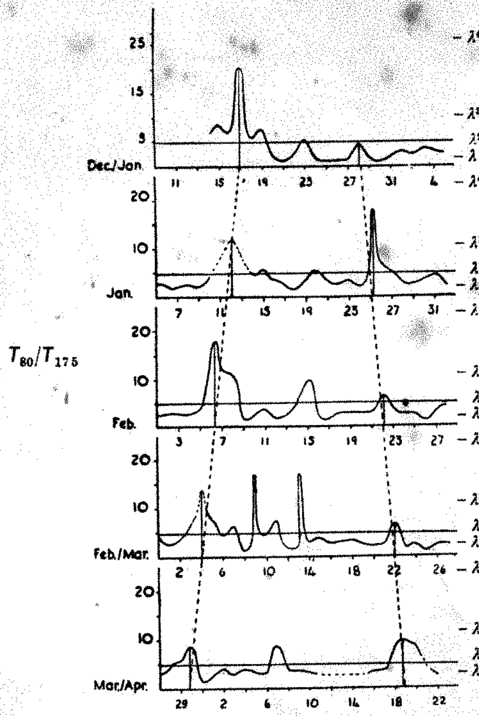

Fig. 3. RATIO OF EQUIVALENT SOURCE TEMPERATURES ON 80 MC./S. AND 175 MC./S. (T_{80}/T_{175})

It has been suggested by Appleton and Hey[2] that there is a definite wave-length – intensity distribution for the increased radiation emitted during periods of solar activity, and that observed departures from this distribution are the result of ionospheric influence. The results shown in Figs. 2 and 3 for frequencies of 175 Mc./s. and 80 Mc./s. (which cannot be affected appreciably by the ionosphere) indicate that whereas the general level is consistent with an equivalent temperature which varies as λ^2, there are marked departures from this relation on many days.

An examination of Fig. 3 shows that the occasions when the ratio of the intensities departs appreciably from the average tend to recur with a period of about 27 days, in a manner far more marked than the variations of intensity on either frequency alone. Our results, therefore, suggest that when the ratio of the intensities on the two frequencies assumes abnormal values, it is due to directed emission, the angular distribution of which is different for the two frequencies.

If the recurrence tendency detectable in Fig. 3 is substantiated by further measurements, it seems probable that the day-to-day variations of the intensity of solar radiation are partly due to directed emission with a 'polar diagram' which is a function of frequency, and partly due to variation of the effective temperature or the area of the source, which appears to be largely independent of frequency.

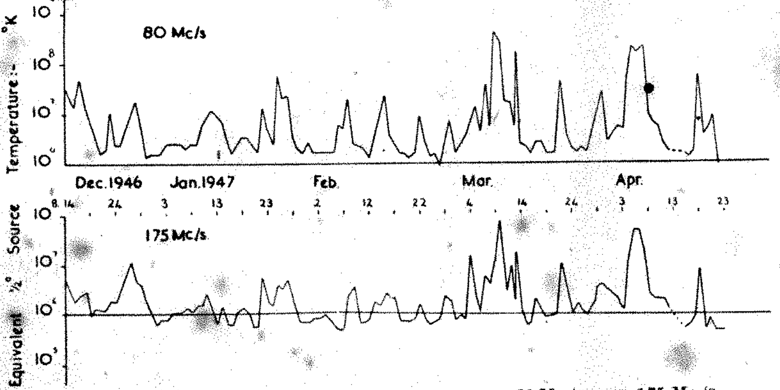

Fig. 2. DAY-TO-DAY VARIATION OF SOLAR RADIATION ON 80 MC./S. AND 175 MC./S.

The curve also suggests that there may be periodicities of 28, 27 and 26·3 days. These may be due to radiation from active regions at different solar latitudes.

Absorption Bands of Li_2, Na_2, K_2 and NaK

Although fairly complete information is available regarding the first two systems of bands of Li_2, Na_2 and K_2, the position with regard to the higher systems cannot yet be considered satisfactory. For this reason the spectra of these alkali-metal molecules, in the regions corresponding to the third, fourth and higher systems of bands, have been investigated in absorption, employing a quartz E_1 spectrograph for lithium, and a 21-ft. concave grating (Eagle mounting), having a dispersion of 1·3 A. per mm., for sodium and potassium. A hydrogen discharge tube has been used as source of continuum below λ 3600 and a tungsten lamp above that.

Li_2: The ultra-violet spectrum of Li_2 has been previously investigated by Vance and Huffman[1]. The bands lie between λ 3500 and λ 3100, and are regarded by them as belonging to four different systems. These, however, appear fragmentary. In the present investigation, the bands have been found to appear most satisfactorily at a temperature of about 1,000° C., using argon gas at a pressure of about half an atmosphere inside the absorption tube to prevent rapid distillation of the metal to cooler parts. Bands appear between λ 3900 and λ 3100, but the heads can be marked clearly only between λ 3500 and λ 3100. All the heads measured are found to belong to a single system represented by the equation:

$$\nu = 30658{\cdot}5 + 231{\cdot}5\,(v' + \tfrac{1}{2}) - 1{\cdot}5\,(v' + \tfrac{1}{2})^2 - 351{\cdot}6\,(v'' + \tfrac{1}{2}) + 2{\cdot}6\,(v'' + \tfrac{1}{2})^2.$$

The upper state of this system is considered to dissociate into 2 ^2S + 3 ^2P atoms. No evidence for other systems is found. The few additional band heads which led Vance and Huffman to conclude that as many as three more systems of bands exist in this region have not been observed in the present investigation. It is difficult to assign any definite reason for their measuring these band heads, as they have not published any value for the intensity of their bands. Another consideration which made them think that there was a case for several systems of bands of Li_2 in this region was analogy with the case of Na_2 which was formerly regarded as having three systems of bands in the corresponding region, namely, λ 3600–λ 3200. This, too, has been disproved, both in previous work[2] and in the present investigation. It seems, therefore, that the Li_2 bands between λ 3500 and λ 3100 really belong to a single system.

Na_2: The sodium molecule has bands in the ultra-violet region extending from about λ 3650 to about λ 2500, which are considered to belong to several systems[2]. Only the bands between λ 3600 and λ 3200 have been photographed in the present investigation for more accurate study. These bands appear well developed at a temperature of about 750° C., using nitrogen or some inert gas in the absorption tube at a pressure of about 5 cm. of mercury. The bands belong to a single system, and their heads can be represented by the equation

$$\nu = 29342{\cdot}0 + 119{\cdot}33\,(v' + \tfrac{1}{2}) - 0{\cdot}53\,(v' + \tfrac{1}{2})^3 - 159{\cdot}23\,(v''+\tfrac{1}{2})+0{\cdot}726\,(v''+\tfrac{1}{2})^2+0{\cdot}0027\,(v''+\tfrac{1}{2})^3.$$

The upper state of this system of bands is considered to dissociate into 3 ^2S + 4 ^2P atoms. The rotational structure of a few bands of this system has also been studied. This indicates that the bands have only two branches and are, therefore, due to $^1\Sigma_u^+ \leftarrow {}^1\Sigma_g^+$ transition. The values of B and r for the upper state are 0·1065 cm.$^{-1}$ and 3·70 A. respectively. It has not been possible to calculate the other constants such as D and α, for which higher dispersion would be necessary.

K_2: The K_2 molecule has been reported to possess bands in the blue and the ultra-violet region down to about λ 3,000[3-5]. Only the bands between λ 4520 and λ 3940 have been studied in the present investigation. The bands belong to two systems: (i) λ 4520–λ 4200; and (ii) λ 4160–λ 3940. The band heads of the first system can be represented by the equation

$$\nu = 22970{\cdot}0 + 60{\cdot}60\,(v' + \tfrac{1}{2}) - 0{\cdot}20\,(v' + \tfrac{1}{2})^3 - 92{\cdot}64\,(v'' + \tfrac{1}{2}) + 0{\cdot}354\,(v'' + \tfrac{1}{2})^2,$$

and its upper state is considered to dissociate into 4 ^2S + 5 ^2P atoms. The heads of the second system can be represented by

$$\nu = 24627{\cdot}7 + 61{\cdot}60\,(v' + \tfrac{1}{2}) - 0{\cdot}90\,(v' + \tfrac{1}{2})^2 + 0{\cdot}001\,(v' + \tfrac{1}{2})^3 - 0{\cdot}003\,(v' + \tfrac{1}{2})^4 - 92{\cdot}64\,(v'' + \tfrac{1}{2}) + 0{\cdot}354\,(v'' + \tfrac{1}{2})^2,$$

with its upper state dissociating into 4 ^2S + 4 ^2D atoms. The K_2 bands between λ 4160 and λ 3940 were previously considered to belong to two different systems[4]. It has been found that even the previous measurements which were attributed to two systems can be combined into a single system, if due allowance is made for some missing bands due to the broadening of the principal series doublet at λ 4045.

NaK: A system of NaK bands in the ultra-violet region between λ 4020 and λ 3540 has been reported by Walter and Barratt[6] and analysed in different ways by Weizel and Kulp[7] and by Uchida[8]. These bands have also been photographed in course of the present investigation on the 21-ft. grating. It has been found that only the bands between λ 4080 and λ 3820 are due to NaK, while the rest of the strong bands of Walter and Barratt which lie between λ 3660 and λ 3540 are due to Na_2. The band heads in the former region can be represented by the equation

$$\nu = 25201{\cdot}0 + 95{\cdot}85\,(v' + \tfrac{1}{2}) - 0{\cdot}94\,(v' + \tfrac{1}{2})^2 - 123{\cdot}29\,(v'' + \tfrac{1}{2}) + 0{\cdot}40\,(v'' + \tfrac{1}{2})^2.$$

The upper state of this system is considered to dissociate into Na 3 ^2S + K 4 ^2D atoms.

Full details will be communicated elsewhere.

Spherical Electronic Waves ?

THE electronic A-waves which were predicted in a recent communication[1] were plane waves, and it is very difficult to picture them. It seems, moreover, that these would be indefinitely extended.

Consider the possibility, therefore, of a spherical wave of the form

$$\mathbf{A} = \frac{e\mathbf{v}'}{cr}\,\psi\left(t - \frac{\mathbf{s}}{\mathbf{u}}\right). \tag{1}$$

It will be noticed that the phase velocity is still $\mathbf{u} = c^2/\mathbf{v}$, but that outside the wave function ψ we have now included a factor similar to the known expression for **A** as excited by a point charge, $\mathbf{v}'$ being the velocity of the 'exciting' electron, **v**, **u** appertaining to the 'exploring' electron. We then find, proceeding as before, that

$$\nabla\mathbf{A} + \frac{\dot{\mathbf{A}}}{\mathbf{u}} = -\frac{ev'_r}{cr^2}\,\psi\left(t - \frac{\mathbf{s}}{\mathbf{u}}\right) + \frac{e\mathbf{f}'}{cr\mathbf{u}}\cdot\psi\left(t - \frac{\mathbf{s}}{\mathbf{u}}\right)\cdot\frac{dt'}{dt}, \tag{2}$$

where $\mathbf{f}'$ is $d\mathbf{v}'/dt'$. The condition that the left-hand side of (2) vanish is

$$\mathbf{f}' = \frac{\mathbf{u}v_r'}{r}\cdot\frac{dt}{dt'}. \tag{3}$$

This would be a very great acceleration, and we infer that (3) is not practicable. In the case $\mathbf{f}' = 0$ (uniform speed of exciting electrons) (2) may be written

$$\nabla\mathbf{A} + \frac{\dot{\mathbf{A}}}{\mathbf{u}} = -\frac{A_r}{r}. \tag{4}$$

The left-hand side may be replaced[1], giving

$$\frac{d}{dt}\left(\frac{m\mathbf{v}^2}{2} + e\varphi\right) = -\frac{A_r}{r}. \tag{5}$$

If A_r is positive (5) gives a decreasing total energy, which means radiation from the exploring electrons; very small, however, as we shall see.

Now when we take into account relativistic changes in mass[2], we require to replace $m\mathbf{v}^2/2$ by mc^2 in (5). For the first term of (5) would become

$$\mathbf{v}\,\frac{d}{dt}\,(m\mathbf{v}) = \mathbf{v}\,\frac{d}{dt}\left[\frac{m_0\mathbf{v}}{(1 - \mathbf{v}^2/c^2)^{1/2}}\right] = \frac{m_0\mathbf{v}\,d\mathbf{v}/dt}{(1 - \mathbf{v}^2/c^2)^{3/2}} = \frac{d}{dt}\,(mc^2); \tag{6}$$

when this is done (9) of the previous note becomes

$$m\mathbf{v}\dot{\mathbf{v}} + e\dot{\varphi}\,(1 - \mathbf{v}^2/c^2) = 0,$$

and this leads to

$$\dot{\mathbf{p}} = \frac{\mathbf{v}^2}{c^2}\,\dot{\mathbf{p}}_\mu \tag{7}$$

instead of to $\dot{\mathbf{p}} = 0$, where $\mathbf{p}_\mu = e\mathbf{A}/c$. Now from (1)

$$\dot{\mathbf{p}}_\mu{}' = \frac{e}{c}\,\dot{\mathbf{A}} = \frac{e^2}{c^2r}\,(\dot{\mathbf{v}}'\psi + \mathbf{v}'\dot{\psi}).$$

Thus

$$m\dot{\mathbf{v}} = \dot{\mathbf{p}} - \dot{\mathbf{p}}_\mu = \left(\frac{\mathbf{v}^2}{c^2} - 1\right)\dot{\mathbf{p}}_\mu = \left(\frac{\mathbf{v}^2}{c^2} - 1\right)\frac{e}{c}\dot{\mathbf{A}} = e^2\,\frac{(\mathbf{v}^2 - c^2)}{c^4r}\left(\dot{\mathbf{v}}'\psi + \mathbf{v}'\dot{\psi}\right). \tag{8}$$

For a stream of electrons all having substantially the same velocity, take $\mathbf{v}' = \mathbf{v}$.

$$\dot{\mathbf{v}}\left[1 + \frac{e^2}{mc^2r}\,\psi\cdot\left(1 - \frac{\mathbf{v}^2}{c^2}\right)\right] = \frac{-e^2}{mc^2r}\left[\left(1 - \frac{\mathbf{v}^2}{c^2}\right)\mathbf{v}\dot{\psi}\right]. \tag{9}$$

While solving the equation let us take $1 - \mathbf{v}^2/c^2$ as unity. We then obtain to the second order

$$\mathbf{v} = \bar{\mathbf{v}}/\left(1 + \frac{e^2}{mc^2r}\,\psi\right), \tag{10}$$

where $\bar{\mathbf{v}}$ is the non-wave-like uniform part of **v**. The component of **v** in the direction of r is obtained by replacing **v** by v_r, so that

$$\frac{A_r}{r} = \frac{e\bar{v}_r}{cr^2}\,\frac{\psi}{1 + \dfrac{e^2\psi}{mc^2r}} = \frac{e\bar{v}_r}{cr^2}\left(\psi - \frac{e^2}{mc^2r}\,\psi^2\right), \tag{11}$$

to the degree of accuracy to which we are working. In view of the minus sign in (5), (11) gives the rate of radiation of electromagnetic energy by the exploring electron (for slowly moving electrons).

The time average of this expression is

$$\left(\frac{\bar{A}_r}{r}\right) = -\frac{1}{2}\cdot\frac{ev_r}{cr^3}\cdot\frac{e^2}{mc^2}\,\psi\psi^*, \tag{12}$$

which is a third-order quantity, as one would expect of electromagnetic radiation. The rate of radiation as expressed by (12) differs from normal, however, in (at least) the following respects.

(*a*) It changes sign with e, being positive for electrons and negative for positrons or protons.

(*b*) It is a maximum if the radiating electron be moving in line with the point of observation.

(*c*) Its absolute value is insignificant except for values of r not greatly exceeding atomic dimensions.

In view of (*c*) any impairment in the energy of the beam would be too small to give rise to observable effects, except when the beam is brought into close contact with matter.

The main point of the present note is to establish that by extending the results of the previous communication to the physically more probable case of spherical waves, the loss of energy in the beam is insufficient to show on instruments, except when the beam is brought into close contact with matter.

The condition

$$d/dt\,(mc^2 + e\varphi) = 0 \tag{13}$$

is satisfied to a sufficient degree of approximation for the beam to appear of constant velocity when moving in a space substantially force-free. In particular, a cathode ray beam *in vacuo* would not be slowed down to a noticeable extent. We may, therefore, regard classical (Lorentz) electrodynamics as probably capable of explaining electronic waves, apart from assigning the phase of the wave, which involves Planck's constant.

Constitution of the Irradiation Product from Stilbamidine

FOLLOWING the observation by Fulton and Yorke[1] that the drug stilbamidine (4 : 4′-diamidinostilbene di-β-hydroxyethanesulphonate) undergoes photochemical change with production of a more toxic substance when its solutions are exposed to light, various investigators have put forward suggestions regarding the constitution of the irradiation product. Barber, Slack and Wien[2] reported that "The product is almost certainly 4 : 4′-diamidinophenylbenzyl carbinol, but rigorous proof is difficult". Goodwin[3], from spectrographic evidence, confirmed that saturation of the ethylenic linkage occurs, while Henry[4] reported that a number of chemical changes are involved, including dimerization.

On exposing a solution of stilbene in benzene for a long period to sunlight, Ciamician and Silber[5] isolated a hydrocarbon of m.p. 163° which from analysis and molecular weight determinations they considered to be a dimer of stilbene $C_{28}H_{24}$. This substance has been prepared in the present investigation by irradiating a similar solution with the light from a mercury vapour lamp, and has been used as a reference compound to show that the product of irradiation of stilbamidine is also a dimer, namely, 1 : 2 : 3 : 4-tetra-(4′-amidinophenyl)-*cyclo*butane. After irradiation of stilbamidine, the toxic product formed was isolated and purified as the sulphate. By hydrolysis with alcoholic potassium hydroxide it was converted to the corresponding tetra-acid which, on decarboxylation, gave the hydrocarbon m.p. 163° mentioned above, along with a small amount of another hydrocarbon of the same empirical composition and m.p. 149°.

The identity of the hydrocarbon m.p. 163° obtained by Ciamician and Silber with that obtained by decarboxylation of the tetra-acid was shown by the fact that both substances gave the same X-ray diffraction patterns. The second hydrocarbon m.p. 149° gave, on the other hand, quite different X-ray patterns. The X-ray data are as follows:

Melting point	163 °C.	149° C.
Crystal system	Monoclinic	Monoclinic
a, *A*	16·99 ± 0·10	20·45 ± 0·10
b, *A*	5·775 ± 0·02	9·40 ± 0·05
c, *A*	12·33 ± 0·08	10·77 ± 0·05
β°	127·0 ± 0·5	92·0 ± 1·0
Space group	P_{2_1}/a (C_{2h}^5)	P_{2_1}/n (C_{2h}^5)
Density (gm./c.c.) at 18° C.	1·23	1·14

For the hydrocarbon m.p. 163°, the observed density is consistent with the unit cell containing four asymmetric units $C_{14}H_{12}$; if these are grouped in pairs to form two molecules of $C_{28}H_{24}$, the resulting molecules must possess centres of symmetry. This is, in fact, the case, as has been shown by a fairly detailed X-ray analysis which shows that this substance is the centro-symmetric isomer of 1 : 2 : 3 : 4-tetraphenyl*cyclo*butane.

For the hydrocarbon m.p. 149°, the asymmetric crystal unit is the molecule, $C_{28}H_{24}$. This molecule may possess elements of symmetry, but these are not, as in the former compound, demanded crystallographically. We believe that this compound is the second isomer theoretically obtainable by dimerization of stilbene, namely, with a fourfold alternating axis of symmetry, but we have at present no evidence.

For the X-ray structure determination of the hydrocarbon $C_{28}H_{34}$ m.p. 163°, no direct analysis is possible, and trial methods were used in the preliminary stages. The method described by Robertson and White[6], involving the use of the small spacing planes with outstandingly strong spectra, gave an early approximation to the structure, which was then refined by three successive Fourier projections on (010) and a Fourier projection on (100). The final projection on (010) is shown in Fig. 1. While it is hoped to refine this analysis further by three-dimensional methods, certain interesting features of the structure are apparent at the present stage.

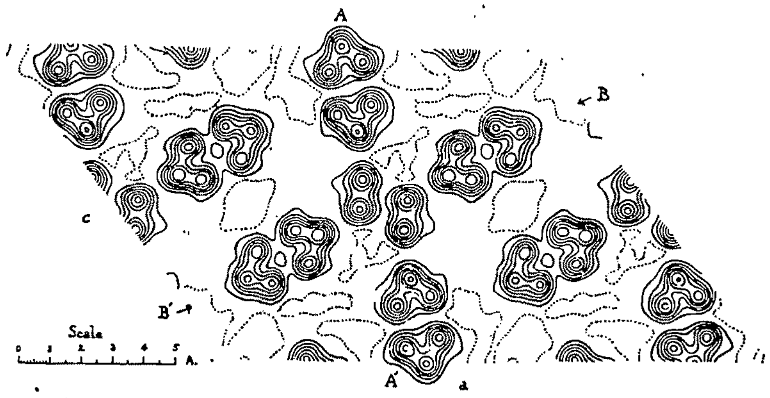

Fig. 1. THE CENTROSYMMETRIC ISOMER OF 1 : 2 : 3 : 4-TETRAPHENYL*cyclo*BUTANE. FOURIER PROJECTION ON (010), SHOWING ONE UNIT CELL

The projection on (010) (Fig. 1) shows clearly that the molecule is indeed 1 : 2 : 3 : 4-tetraphenyl*cyclo*butane; and the orientation of the phenyl groups about the central ring is diagrammatically shown in Fig. 2, where the benzene rings *A*,*A′*, *B*,*B′* are as indicated in Fig. 1.

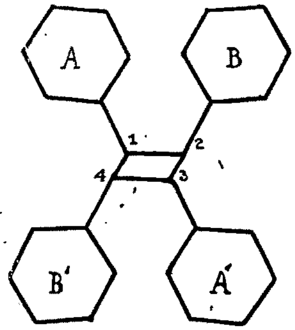

Fig. 2. DIAGRAMMATIC REPRESENTATION OF THE MOLECULE

The configuration about 1–2, 3–4 is *cis*-, while about 2–3, 1–4 it is *trans*-, and the different steric relationships of the phenyl groups about these bonds appear to be associated with considerable distortion of the cyclobutane ring. The ring is necessarily planar (owing to the presence of the centre of symmetry), but it is found to be rectangular rather than square. The observed dimensions are 1·63 A. for 1–2 and 2–3, 1·49 A. for 2–3 and 1–4, and 2·21 A. for the diagonals.

The value 1·63 A. is considerably larger than the normal carbon–carbon single-bond distance 1·54 A., but it is unlikely that it is subject to an error of more than 0·05 A. The other interatomic distances observed are approximately as expected; the benzene rings are found to be regular hexagons of side 1·39 A. (to within 0·03 A.), and the bonds connecting the benzene rings to the *cyclo*butane ring measure 1·52 A. At the present stage of the analysis, however, it would be virtually impossible to reconcile the data obtained with a square central ring.

In the second isomer, m.p. 149°, no distortion of the *cyclo*butane ring is expected to occur, but structure analysis has not so far been carried out for this substance.

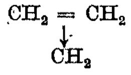
Formulæ for Ethylene Oxide and Cyclopropane

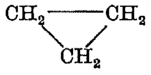
DR. A. D. WALSH[1] has misunderstood my criticism[2], which was not directed against his applications of wave mechanics but against the proposed symbols for ethylene oxide and cyclopropane and also against his statements relating to the reaction types of these substances. His further elaborations are of great intrinsic interest but irrelevant to the issues mentioned.

Dr. Walsh maintains that the hybridization of the three forms of (I) does not give (II):



$$\begin{array}{c} CH_2 = CH_2 \\ \downarrow \\ CH_2 \end{array}$$

(I)



(II)

That can only be justified by attributing to (II) some special significance in regard to the distribution of covalency electrons which is no part of the usual conventional meaning of the symbol. It will accommodate *any* such distribution of six covalency electrons which fulfils the requirements of symmetry. The formula represents only the mean position in space of the atoms (kernels) and the mode of binding (that is, the structure disclosed by analysis, synthesis, X-ray crystal evidence, etc.).

It is a further step to the space models which again concentrate attention on the atoms rather than on the distribution of valency electrons. We know that the environments of the carbon atoms in cyclopropane derivatives are tetrahedral (not, usually, *regular* tetrahedral), and this is true whether the valencies are trigonal or not. Incidentally, Dr. Walsh says that the atoms are *near*-trigonal, but that would appear to mean tetragonal, although of a very distorted type. The formula (II) is, therefore, entirely satisfactory unless we read more into it than was ever intended. On the other hand, (I) is unsatisfactory because its more important implications are lost on hybridization. It suggests that the carbon atom at the business-end of the arrow is negatively charged; this is not true of the hybrid. It suggests that this carbon atom makes no valency-electron contribution to the bond; again this is not true of the hybrid. It is obvious that any reaction-type implications of (I) are also lost on hybridization. Why should we adopt a formula, each unique feature of which is destroyed by mental reservations, or by the clumsy device of writing three symbols?

Dr. Walsh now finds that the wave-mechanical picture of ethylene oxide allows of *some* resemblance to acetaldehyde. I can only repeat that the chemical resemblance is very close indeed, that the analogy with ethylene is non-existent, and the parallel with amine-oxides is exiguous. The reaction encountered by Karrer[3] is readily explicable by reduction to a tertiary alcohol, a type of process that I mentioned previously[2]. In the presence of an acid catalyst such a substance would suffer dehydration with great facility, especially in these instances where the product is so fully conjugated. This example was naturally not mentioned by me because it is far from representative. If ordinary ethylene oxides were analogous to amine oxides, they should be convertible to ethylenes by mild reducing agents, and that is certainly not the case.

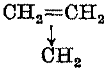
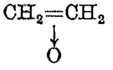
Structure of Ethylene Oxide and Cyclopropane

A. D. WALSH[1] has suggested that the properties of cyclopropane and ethylene oxide are better accounted for by the formulæ I (three equivalent resonance forms) and II than by III and IV:



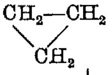
$$\begin{array}{c} CH_2{=}CH_2 \\ \downarrow \\ CH_2 \end{array}$$

I

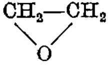


$$\begin{array}{c} CH_2{=}CH_2 \\ \downarrow \\ O \end{array}$$

II



III



IV

One consequence of this suggestion is that, in the CH-bonds, the carbon orbitals should be of the sp^2 hybrid type, rather than the sp^3 hybrid suggested by III and IV. In 1945 I obtained the force constants of a number of CH-bonds and found the following: methane, 4·97 (in the usual units); ethane, 4·81; ethylene (sp^2 bonds), 5·1 [2]. Fox and Martin[3] have suggested that in paraffins the CH-force constant is: CH_4, 5·04; CH_3 group, 4·75; CH_2 group, 4·56; CH group, 4·56. The force constant of the CH-link in cyclopropane and ethylene oxide might, therefore, prove valuable in deciding between the above structures.

From the Raman[4] and infra-red[5] spectra of cyclopropane it has been decided that the CH-valency vibration frequencies are: A_1', 3,000; E', 3,000; A_2'', 3,050; E'', 3,080 cm.$^{-1}$. The derived force constants are: 5·04, 5·04, 4·91 and 5·02. The mean is 5·0. (The same values of the fundamental constants have been used as in my previous paper[2].) The Raman[4] and infra-red[5] spectra of ethylene oxide indicate that the CH-valency vibration frequencies are A_1, 3,000; B_1, 3,000; B_2, 3,062; A_2, 3,062 cm.$^{-1}$. The derived force constants are 5·04, 5·04, 4·95 and 4·95. The mean is again 5·0. Ethylene sulphide is also of interest. Thompson and Dupré, having examined the Raman and infra-red spectra, suggested for the CH-valency vibrations: A_1, 2990; B_1, 2,990; A_2, 3,080; and B_2, 3,080 cm.$^{-1}$ [6]. The derived force constants are 5·00, 5·00, 5·02 and 5·02. The mean may be taken as 5·0. In all these three compounds the CH-force constant is 5·0.

For the CH-bond in a methylene group in an ordinary paraffin chain, we would expect the force constant to be about 4·6 (Fox and Martin), and certainly not greater than 4·8 (CH_3-group). The force constant in the methylene groups in these ring compounds is certainly significantly greater than this. It is, moreover, nearer the ethylene figure of 5·1 than to the figure for a methylene group in a paraffin. (It seems proper to make the comparison with the CH_2-group in a paraffin chain, though it may be noted that the CH-force constant in these ring compounds is not appreciably different from that in methane itself.) The conclusion to be made from these calculations must be that the force constants indicate that the CH-links in these ring compounds approach those in ethylene. So the calculations provide a measure of support for Walsh's suggestion. Of course, the CH-force constant might change simply as a result of the distortion in the angle between the bonds which form the ring. However, such a change is hypothetical, and it is, therefore, rather unsatisfactory as an explanation of these results.

The possible usefulness of the above calculations became apparent to me after hearing a lecture by Dr. Walsh on this and related topics.

Fluorescence 'Fatigue'

Use of the term fluorescence 'fatigue'[1] to describe the decrease in fluorescence which is observed in many substances on continued irradiation, both in the solid state and in solution, is to be deprecated as it naturally implies something analogous to the well-known phenomenon of elastic fatigue; or to muscular fatigue. It is scarcely conceivable that any process at all comparable with either type of fatigue can occur in the case of a fluorescent molecule, particularly in dilute solution, and the only satisfactory explanation of any observed change of fluorescence with time of exposure to the exciting radiation, at any rate in dilute solution, is that photochemical changes occur which result in a change in the concentration of the molecular species responsible for the fluorescence. Recently published work[2] on the photochemical instability of stilbamidine made extensive use of the brilliant fluorescence of the *trans*-form of this compound to elucidate the nature of the photochemical changes which occur, and the above view is certainly amply justified in this case, the changes being concurrent dimerization and *trans*-*cis*-isomerization in proportions depending on concentration and temperature.

Neither *cis*-stilbamidine nor the product of the dimerization of *trans*-stilbamidine exhibits any fluorescence in the visible spectrum, but appropriate irradiation of solutions of these compounds results in a steady *increase* from zero in the intensity of fluorescence. This development of fluorescence on continued irradiation has been shown to be due, in each case, to partial conversion of the compound into *trans*-stilbamidine. The changes in fluorescence which solutions of these compounds exhibit on irradiation can therefore be explained completely in terms of the photochemical changes which occur. If the fading of the fluorescence of a solution of *trans*-stilbamidine on irradiation is to be attributed to a fluorescence 'fatigue', to what effect is the increase of the fluorescence of solutions of *cis*-stilbamidine and the dimer to be ascribed?

The change which the fluorescence of a solution of riboflavin undergoes on irradiation can also be quite adequately explained in terms of the photochemical changes which occur. This can be readily demonstrated by spotting-out the solution on filter-paper after varying periods of irradiation, washing radially[3] with water and examining the dry filter-papers in ultra-violet light. The steady disappearance of riboflavin from the solution, and the steady formation of a substance with a bluish fluorescence and greater adsorbability on filter-paper than that of riboflavin, which enables separation of the two compounds to be effected, is immediately apparent.

The importance in fluorimetric analysis of the dependence of fluorescence intensity upon time of irradiation is, of course, fully appreciated. The large effect on fluorescence which change of temperature sometimes produces must also not be overlooked. This is probably due in the main to modification of the course of some photochemical change which the fluorescent compound undergoes. Recovery of fluorescence on discontinuing irradiation can be attributed to reversal of a photochemical change taking place as a dark reaction.

The Name of Element 23

Prof. F. A. Paneth[1] has made certain suggestions in connexion with the naming of new elements. We quote the following: "(1) The right to name an element should go to the first to give definite proof of the existence of one of its isotopes. . . . (3) If a claim to such a discovery has been accepted in the past, but is refuted by later research, the name given should be deleted and replaced by one chosen by the real discoverer."

These rules seem to apply fittingly to the case of element 23, at present called vanadium, to which we wish to direct attention. The facts relating to its discovery, so far as known to us, are as follows:

In 1801 Andrés Manuel del Río, professor of mineralogy at the Royal School of Mines of Mexico, thought he had found in ores from Zimapán, Hidalgo, Mexico, a new element which he named 'erythronium'. He published his findings in "Tablas Mineralógicas" in 1804 [2]. In 1802 del Río gave samples containing the new element to Alexander von Humboldt, taking advantage of the latter's visit to Mexico[3]. Von Humboldt took these samples with him to Paris on his return to Europe and gave them to M. Collet-Descotils, asking for a report on del Río's claim. Collet-Descotils analysed del Río's samples and reported—erroneously—that they contained only chromium[4]. At that time von Humboldt accepted this verdict and therefore rejected del Río's claim as invalid.

The facts relating to Sefström's discovery of vanadium in 1830, and to Wöhler's work[5] establishing the identity of 'erythronium' and vanadium, are well known. Here we would only like to add that in 1831 both Berzelius[6] and von Humboldt[7] recognized del Río's priority as valid.

As a consequence of a conversation held between del Río and von Humboldt, the former gave up temporarily his claim to the discovery of a new element, accepting that what he had really found was chromium[8]. He held to this point of view after the publication of Collet-Descotils' error[9].

From the preceding historical facts, it follows that the real priority for the discovery of element 23 belongs to Andrés Manuel del Río. Our main purpose is to emphasize that under the rules suggested by Prof. Paneth, del Río's choice for the name of this element should stand. Element 23 should, therefore, be called 'erythronium' and not vanadium. Whether this change in accepted chemical nomenclature of long standing is at all possible is here neither implied nor suggested. Paneth's rules, however, either should be applied uniformly to all cases they are meant to cover, or to none at all.

[9] *Diario de México*, 15, No. 2170, 294–295 (México, Sept. 11, 1811). *Mercurio de Espana*, 172–175 (Madrid, Feb. 1819). *Annalen der Physik von Gilbert*, 71, 7/12 (1822).

THE foregoing letter may create the impression that Del Río only "temporarily" abandoned his claim to the discovery of erythronium, misled by "Descotils' error" and Humboldt's persuasion. This, however, is not the story he himself tells in his last contribution to the subject[1]. In discussing the chemical composition of the Zimapan lead ore, he not only stresses the point that it contains no other element than the lead chromates, but ascribes to himself the merit of this 'discovery'. He states that he had published the correct analysis one year before Descotils, and attacks Humboldt for intentionally suppressing this fact and giving credit to a French chemist out of spite against the Spanish. Not a single word is said about the old erythronium claim, which he seems very anxious to consign to oblivion.

The rule suggested says that the right to name an element should go to the first to give *definite* proof of its existence. It is difficult to see how Del Río could be included under this heading, in view of his quick, complete and lasting change of front—even if we may have some doubts whether his recantation actually preceded the Paris analysis, as he so emphatically claims.

Naming the Elements: a Former Suggested Use of 'Plutonium'

IN view of the recent naming of new elements, the following two quotations, which have lately come to my notice, may interest or amuse historians of science. They refer to an early *claim* that barium oxide can be reduced by the oxyhydrogen blowpipe. In Thomas Thomson's famous "System of Chemistry" (5th edit.; London, 1817), vol. 1, p. 342, we read: "Dr. Clarke has decomposed barytes by exposing it to an intense heat, produced by the combustion of a stream of oxygen and hydrogen gas, mixed together in the requisite proportions to form water. He has given to the metal of barytes the name of *plutonium*." It appears that, in this quotation, "barytes" means barium oxide and not the sulphate, as now (see below).

Edward Daniel Clarke (1769–1822) was, from the end of 1808 until his death, professor of mineralogy at Cambridge—he was the first occupant of the chair—and his life, travels and work are duly recorded in the "Dictionary of National Biography". Again, in the "Life and Remains of Edward Daniel Clarke" by the Rev. W. Otter (London, 1825), vol. 2, p. 455 (footnote), we read (Dr. Clarke speaking; date 1819): "In proposing the substitution of Plutonium, instead of Barium, for the name of the metal of Barytes, the author was actuated solely by a regard to truth, as essential to science. The impropriety of naming one of the lighter metals, from βαρὺς signifying *heavy*, will surely be obvious, when it now appears that the name implies an untruth. The specific gravity of the metal of Barytes equals 4·000. With what propriety, therefore, can it be denominated Barium, the heavy metal? . . . The metal of Barytes, in whatsoever manner its presence may be demonstrated, owes all the proofs of its existence to the dominion of fire; hence the propriety, at least, of giving to it the name of Plutonium.". Incidentally, the modern value for the specific gravity of metallic barium is 3·78.

In 1774, Scheele discovered a new earth in native manganese dioxide (which often contains barium as an impurity), and Gahn in 1775 found that this earth is a constituent of 'heavy spar' ($BaSO_4$). It seems that the *earth* was called 'barote' by Guyton de Morveau, 'barytes' by the Irish chemist, Kirwan, and 'baryta' by Lavoisier. Barium was isolated electrolytically by Davy in 1808.

As history would have it, Davy's name, 'barium', for the metal remained, in spite of Clarke's ingenuous logic; but we may now hail the unexpected return to the service of science of its former rejected rival.

FULMER RESEARCH INSTITUTE

By E. A. G. LIDDIARD
(Director)

THE opening of the Fulmer Research Institute at Stoke Poges, Bucks, by Sir Stafford Cripps (see p. 150) marks the beginning of a new experiment in industrial research, the progress of which should be followed by all who are interested in the organisation of research in Great Britain. Briefly, the object of the Fulmer Research Institute, Ltd., is to provide research facilities which can be used to carry out research privately for any sponsor, or group of sponsors, the results arising from the research remaining under the control of the people who pay for the work. Its closest parallel is in the Battelle Memorial Institute or the Mellon Institute in the United States.

The suggestion has often been made, both in the editorial columns of *Nature* and elsewhere, that there is room in Great Britain for this type of research institute. This opinion is not invariably accepted, particularly by strong supporters of the research association movement, on the erroneous assumption that such an institute would compete with research associations. At the moment, fundamental research work in Britain is mainly carried out at the universities, and industrial research work either by the private laboratories associated with the works of individual firms or by research associations. Research associations have been particularly successful in solving problems which are common to all sections, and in educating industry in the scientific methods of approach to their problems. They also provide an excellent pool for the exchange of technical information which benefits the industry as a whole. The research associations have the advantage that the cost of researches is borne by many subscribers whose individual contributions are small in relation to the cost of the researches, and much more work can therefore be done than would be possible if the research work was left to be financed by the individuals concerned. The Department of Scientific and Industrial Research grant and the freedom they enjoy from rates and taxes put the research associations in a favourable financial position.

The limitation of a research association, however, lies in the absence of any mechanism for developing really new, original and individualistic ideas. The most advanced firms in any industry are not often prepared to put forward their very brightest ideas for the research association to work upon for the benefit of the whole industry. Research programmes of research associations are usually arranged on democratic lines by committees representing the industry, which restricts the activities of the research associations to problems in which the majority of the industry is interested but which are either beyond the resources of an individual member or are not considered to be sufficiently urgent or important to take up the time of the research department of individual members.

What, then, is the position of a concern wishing to develop an original idea or a new process of manufacture to help it to compete successfully in the world's markets ? In the absence of an institute where sponsored research is carried out confidentially, the choice lies between making the idea and the results of any research work on the idea generally known; when it becomes of equal value to competitors, or of collecting together the necessary specialized staff and equipment to do the work in its own laboratories. This entails considerable capital outlay, and, when the work is completed, the profitable use of the staff and equipment may present a difficult problem.

There remained, therefore, an important gap in our organisation of research, and in filling that gap there is no question of competition between an institute for sponsored research and a research association.

In the situation in which Great Britain finds itself to-day, we are told that we must export. Some of the most important assets of the country are the brains and ideas of its scientific workers ; these are at present mainly being used for the provision of knowledge which is available to the world at large. For pure scientific work this arrangement is ideal, but we are living in a competitive age, and it would seem to be common sense to do all we can to capitalize in the national interest our assets in the form of applied science. This can only be done effectively if the results of research remain in the hands of people capable of making full use of them. For example, a new process which may follow from research at a university becomes available equally all over the world, and is everybody's or nobody's property ; in fact, research work done in Great Britain has often been applied abroad before it is used at home. But where the results of research work are owned by an individual sponsor, any process arising from them can be used to increase our exports or, if patentable or negotiable, can result in increased national income from royalties, etc.

The Fulmer Research Institute aims eventually at carrying out research in a wider field, but to begin with, will concentrate on metallurgical and allied problems. Equipment and staff will be available to tackle most forms of metallurgical research, and work may be placed there in the knowledge that the results will be treated confidentially and that they may be exploited by the sponsor for his sole benefit. Provision has been made whereby nominees of the people who sponsor a research can come to work in the laboratories on the development of new industrial processes and can go back to the sponsor when the work is completed, carrying with them the knowledge that they have gained in the laboratories.

The idea of such an Institute was conceived by Colonel W. C. Devereux, who, having studied the system of sponsored researches in operation in the United States at the Battelle and Mellon Institutes, became convinced that a similar institution is needed in Great Britain. The Fulmer Institute is non-profit-making, in the sense that there will be no distribution of dividends. Charges for research are based on cost of salaries and materials, plus a small margin which will be available for the future expansion and further equipping of the Institute. Work is not undertaken on one problem for more than one sponsor unless the original sponsor agrees to share both the cost and the results of the research. Publication of the research results will be at the discretion of the sponsor ; but the Institute will advise publication wherever practicable, particularly where the results of the research can be covered by patents which, of course, become the property of the sponsor.

The size of the Institute can be assessed from the fact that the total floor area is approximately 20,000 sq. ft. Chemistry, corrosion, vacuum, engineering, physics and metallography sections are housed in the main building (a converted country mansion), together with the library, offices and canteen. A new building contains the machine shop and the experimental casting and heat-treatment laboratories. Twelve out of a total staff of forty are graduates, and the staff includes chemists, physical chemists, physicists and engineers as well as metallurgists.

The most important researches at present in progress are in the development of new alloys for service at high temperatures; researches on aluminium base alloys (these are in charge of Dr. A. H. Sully); and on a process for refining impure aluminium by catalytic distillation based on the existence of monohalides of aluminium stable at low pressures and high temperature which can be formed by passing the normal trivalent halides over aluminium at high temperatures and low pressures. They decompose to the metal and the trivalent halide at lower temperatures. This work is being carried out by a team under the direction of Dr. P. Gross. The principle is likely to be applicable to other metals, and sponsorship for researches on the refining of other metals on this principle is sought.

Although the Institute is prepared to consider any type of research work, the staff and equipment are such that problems in physical metallurgy, corrosion and finishing, the development of new casting processes and in the application of thermodynamics to metallurgical problems are likely to be tackled most successfully.

A certain proportion of short-term work involving mechanical and analytical testing and advice and information on technical problems is also undertaken and constitutes an important but not a major part of the Institute's activities.

SURFACE TENSION IN LIQUIDS

By C. GURNEY

THERE is ample experimental evidence that the free surface of liquids is in a state of tensile stress, but this stress has never been satisfactorily explained in terms of the positions and motions of molecules. It is generally recognized that liquids cannot permanently withstand shear, and yet a two-dimensional tensile stress implies shear in all planes inclined to the plane of the tension. How is this possible? The most acceptable previous explanation is that due to Bakker[1], which has recently been discussed by R. C. Brown[2]; but the Bakker theory is not very satisfying, as it is an attempt to show that the surface of a liquid could be in a state of effective tensile stress without an associated shear stress. The failure to explain the tension stress in the surface of liquids has led many writers to regard it as unreal. Authors who have referred to the stress as a 'fiction' include Laplace, Rayleigh and N. K. Adam. Adam[3] also writes, "The surface tension does not exist as a physical reality". J. Rice[4], in his commentary on Gibbs' papers on surface phenomena, is at pains to absolve Gibbs from having the notion that the surfaces of liquids are in a state of tension stress.

By giving a molecular interpretation to the thermodynamics of surfaces as developed by Gibbs, I give below what seems to be a satisfying explanation of the tension stress in the planes of surfaces, and which appears to have some novel features. Gibbs introduced into thermodynamics a quantity (μ) which he called the intrinsic potential of a substance. Subsequent authors have called this quantity partial molal free energy, chemical potential, etc. For equilibrium between phases and between each part of a heterogeneous phase, Gibbs showed that the intrinsic potential of the parts of each component substance must have the same value throughout the system. The intrinsic potential is a measure of the escaping tendency of molecules. Molecules tend to escape from regions of high μ and to migrate to regions of low μ. Equality of the intrinsic potentials ensures that just as many molecules of each species enter each region as leave it. This condition is therefore similar to the equation of continuity in fluid mechanics; but in thermodynamics we are dealing with random motion of molecules, whereas fluid mechanics deals with organised motion. At a given temperature, intrinsic potential depends on the arrangement and relative position of molecules. Molecules at a free surface or at an interface between two different substances have a different environment from interior molecules, and they would, therefore, be expected to have different intrinsic potentials, whereas for equilibrium they must have the same intrinsic potential as interior molecules. How then can equilibrium be achieved? At this stage it may be helpful to consider another case of thermal equilibrium.

Consider a pure substance, say lead, in equilibrium with its liquid. When stress-free, there is only one temperature at which this equilibrium can occur. At this temperature the intrinsic potentials of solid and liquid are equal. At room temperature, solid lead has the smaller μ, and in consequence the solid phase is stable. How could we have solid and liquid lead in equilibrium at room temperature? The answer is that stress must be applied to the solid or liquid or both, until their intrinsic potentials are equal. In principle at least we could apply pressure to the solid to increase its intrinsic potential to that of the stress-free liquid, or we could apply hydrostatic tension to the liquid to decrease its intrinsic potential to that of the stress-free solid. For two-phase equilibrium there is thus a relationship between stress and temperature. By making use of the relationships

$$\frac{\partial\mu}{\partial p_{Tn}} = \bar{v} \text{ and } \frac{\partial\mu}{\partial T_{pn}} = -\bar{s}, \quad . \quad . \quad (1)$$

(where p, T, and n are pressure, temperature, and quantity of substance respectively and $\bar{v}$ and $\bar{s}$ are specific volume and specific entropy), the relationship between p and T for the case in which the liquid only is subjected to pressure is

$$\frac{dp}{dT} = \frac{L}{T\bar{v}}, \quad . \quad . \quad . \quad (2)$$

where L is the latent heat of the solid-liquid transition. The equilibrium pressure on the liquid thus increases with temperature; at low temperatures (below the stress-free melting point) the equilibrium pressure is negative. In principle, therefore, we could have solid and liquid lead in equilibrium at room temperature by applying a hydrostatic tension to the liquid.

It is now only a small step to the explanation of the tension in the free surface of a liquid. In the absence of stress, surface molecules have a higher μ than interior molecules. For equilibrium, stress must be applied to the surface or interior or both, to make the intrinsic potentials of surface and interior molecules equal. As the surface molecules have the higher μ, it is easy to see, by analogy with the solid-liquid equilibrium case, that the stress which must be applied to maintain equilibrium is a tension in the plane of the surface. The thermodynamic relations are

$$\frac{\partial\mu}{\partial\gamma_{Tn}} = -\bar{A} \text{ and } \frac{\partial\mu}{\partial T_{\gamma n}} = -\bar{s}, \qquad (3)$$

where γ is the surface tension, $\bar{A}$ is specific area and $\bar{s}$ is the specific entropy of the surface. The relationship between surface tension and temperature is

$$\frac{\partial\gamma}{\partial T} = -\frac{L}{T\bar{A}}, \qquad (4)$$

where L is the latent heat of the liquid-surface transition. The difference in sign of expressions 2 and 4 is due to the fact that tension and pressure must be considered to be of opposite sign. The expressions are similar because the tension stress in the surface of a liquid is there for the same reason as would be the hydrostatic tension on a liquid in equilibrium with its solid, at a temperature below the stress-free melting point. The tensions are necessary to reduce the intrinsic potentials of the surface in the one case, and the liquid in the other, so that they equal the intrinsic potentials of the adjacent phases.

A more detailed picture of how the tension stress reduces the intrinsic potential of surface molecules may be obtained as follows. When a molecule escapes from the surface of a liquid, the neighbouring surface molecules move so as to fill up the hole which would otherwise be left by the escaping molecule. The area of the surface is thus reduced by the effective area of the escaping molecule. If acting in the plane of the surface, there is a constant tension force (γ); work must be done against this force which equals γA, where A is the effective area of a molecule. At the same time, the strain energy associated with the molecule is lost. This amounts to $\int_{A_0}^{A}\gamma dA$, where A and A_0 are the effective areas occupied by a molecule when the surface is under tension γ and zero force respectively. The net work done by the tension in the plane of the surface when a molecule escapes from the surface is therefore

$$-\gamma A + \int_{A_0}^{A}\gamma dA = -\int_{0}^{\gamma} A d\gamma. \qquad (5)$$

The right-hand side of this expression when differentiated and computed per unit mass instead of per molecule is equal to $-\bar{A}$, which by the first of equations (3) is equal to $\partial\mu/\partial\gamma$. The tension in the surface, therefore, reduces the intrinsic potential of the surface, because of the work done against the tension when a molecule escapes from the surface.

For substances in which the range of molecular action exceeds the effective dimensions of a molecule, the intrinsic potential of molecules near, but not actually in, the surface would exceed that of interior molecules, and some tension force (although it will be much smaller than that necessary between the outermost molecules) will be necessary to reduce their μ to that of interior molecules. The surface tension must thus be regarded as acting over a region a few molecules thick, the intensity of the force decreasing rapidly with increasing distance from the surface.

We are now in a position to discuss how the tension is set up and maintained. Imagine a stress-free surface of given area. The μ of surface molecules is higher than that of interior molecules. More molecules, therefore, leave the surface than enter it, so that fewer molecules are left to occupy the given area of surface. Their spacing in the plane of the surface therefore exceeds the stress-free spacing, and a tension stress is set up between them. Molecules continue to leave the surface until the tension stress is increased to that necessary to equalize the intrinsic potentials of surface and interior molecules. At this stress, equilibrium is attained, and just as many molecules enter the surface as leave it. The equilibrium tension is then automatically maintained. There is no need to postulate any special orientation of surface molecules or to try to show that there is no shear stress associated with the tension. The tension stress in the surface is continually trying to relax, but as fast as it does so the μ of surface molecules is increased, and then more molecules leave the surface than enter it until the surface is tightened up. If for any reason the tension became too high, the intrinsic potential of the surface would be too low, and more molecules would enter the surface than leave it, until the tension in the surface was slackened off. This is a fascinating process. In the plane of the surface of a liquid so mobile that millions of molecules per square centimetre are entering and leaving the surface per second, there exists a tension force which cannot relax.

INTRODUCTION OF NEW ELECTRICAL AND LIGHT UNITS

SIR CHARLES DARWIN, director of the National Physical Laboratory, has issued the following announcements with regard to the introduction of new electrical and light units, in accordance with the decisions taken by the International Committee of Weights and Measures at its meeting in Paris in October 1946.

Electrical Units

The system of electrical units employed at present at the National Physical Laboratory are the 'international' units, which are based on certain material standards. From January 1, 1948, the units employed will be those derived from the centimetre, gram and second, that is, the so-called 'absolute' units. The effects of this change may be seen from the following table:

1 international ohm = 1·00049 'absolute' ohms
" volt = 1·00034 " volts
" ampere = 0·99985 " ampere
" watt = 1·00019 " watts
" henry = 1·00049 " henries
" farad = 0·99951 " farad

The factors given in this table apply to the mean international units; that is to say, to the mean values of the international units as realized at the various national laboratories.

After January 1, 1948, apparatus submitted to the Laboratory with the view of the issue of a National Physical Laboratory Certificate of Examination will be regarded as acceptable if its errors fall within the specified limits when the values are expressed in either international or absolute units, provided that it was manufactured before January 1, 1949, and is marked accordingly. Apparatus manufactured after that date, and any apparatus not marked with the date of manufacture, will be acceptable only if its errors fall within the specified limits when the values are expressed in absolute units.

Unit of Light

The National Physical Laboratory will, on and after January 1, 1948, express all photometric values in terms of units based on the 'new candle'. This unit of luminous intensity is of such a magnitude that the brightness of a full (or cavity) radiator (black body) at the temperature of solidification of platinum is 60 'new candles' per square centimetre. The 'new lumen' is the luminous flux radiated within unit solid angle by a uniform source having a luminous intensity of one 'new candle'. The new unit of illumination will be one 'new lumen' per unit area. One 'new lumen' per sq. ft. will also be called one 'new foot-candle', and one 'new lumen' per sq. metre one 'new lux'. The new unit of brightness will be one 'new candle' per unit area, and, alternatively, one 'new foot-lambert'. The latter unit is defined as the brightness of a perfectly diffusing surface of 100 per cent reflexion factor when its illumination is one 'new lumen' per square foot.

When differences of colour are involved in the determination of any magnitude in terms of the above units, the evaluation will be in accordance with that which would be obtained by an observer having the relative luminosity curve (the curve connecting eye sensitivity with wave-length) adopted by the International Commission on Illumination in 1924 and later by the International Committee of Weights and Measures.

The differences between the new units and those in use hitherto are small. The present units, based on the 'international candle', were introduced on April 1, 1909, in Great Britain, France and the United States of America, and were adopted in 1921 by the International Commission on Illumination. Nevertheless, Germany and some Central European countries continued to use units based on the Hefner candle (about 0·9 international candle). The international candle was not based on any primary standard; it was derived from the units defined in terms of the old flame standards, and was maintained by means of carbon and tungsten filament electric lamps. Further, the values of the unit at different colour temperatures did not exactly agree, when compared on the basis of the international relative luminosity curve adopted in 1924.

The magnitude of the new unit has been so chosen that it will introduce only very small changes (less than 0·5 per cent) in the values of luminous intensity assigned to lamps operating at a colour temperature of about 2,360° K. For lamps at considerably higher colour temperatures, for example, ordinary gas-filled electric lamps at normal efficiencies, the values expressed in terms of the 'new candle' will be several per cent lower than those expressed in international candles. At the colour temperature of the primary standard (2,046° K.), values in terms of the 'new candle' are about 1·7 per cent higher than those in terms of the international candle.

On account of this alteration in the basis on which sources of light of different colours are compared, it is impossible to give a factor for converting values in international candles to values in 'new candles'.

U.S. NATIONAL ACADEMY OF SCIENCES

Elections and Awards

At the annual meeting of the U.S. National Academy of Sciences held in Washington during April 28–30, the following officers, members, and foreign associates were elected:

President (July 1, 1947–June 30, 1951): Alfred N. Richards, vice-president in charge of medical affairs, University of Pennsylvania (in succession to Dr. Frank B. Jewett).

Home Secretary (re-elected for a further term of four years ending June 30, 1951): F. E. Wright, Carnegie Institution of Washington, Washington, D.C.

Members of the Council of the Academy (for a three-year term ending June 30, 1950): W. Albert Noyes, jun., chairman, Department of Chemistry, University of Rochester, Rochester, N.Y.; and Donald D. Van Slyke, chief chemist, Hospital of the Rockefeller Institute for Medical Research, New York City.

Members: Luis W. Alvarez, professor of physics, University of California, Berkeley, California; Robert F. Bacher, U.S. Atomic Energy Commission, Washington, D.C.; Paul D. Bartlett, professor of chemistry, Harvard University, Cambridge, Mass.; Jacob Bjerknes, professor of physics, University of California at Los Angeles, California; Francis G. Blake, dean of Yale University School of Medicine, New Haven, Conn.; R. Alexander Brink, chairman of the Department of Genetics, University of Wisconsin, Madison, Wisconsin; Ralph W. Chaney, professor of paleobotany and curator of paleobotany, Museum of Paleobotany, University of California, Berkeley, California; Arthur C. Cope, professor in charge of the Department of Chemistry, Massachusetts Institute of Technology, Cambridge, Massachusetts; Farrington Daniels, professor of physical chemistry, University of Wisconsin, Madison, Wisconsin; Arnold Gesell, director, Clinic of Child Development, Yale University School of Medicine, New Haven, Connecticut; James Gilluly, professor of geology, University of California at Los Angeles, California; R. B. Goldschmidt, professor of zoology, University of California, Berkeley, California; Samuel A. Goudsmit, professor of physics, Northwestern University, Evanston, Illinois; C. H. Herty, jun., research engineer and assistant to vice-president, Bethlehem Steel Company, Bethlehem, Pennsylvania; Frederick L. Hisaw, professor of zoology, Harvard University, Cambridge, Massachusetts; Wolfgang Köhler, professor of psychology, Swarthmore College, Pennsylvania; L. G. Longsworth, associate member, Rockefeller Institute for Medical Research, New York City; Edwin M. McMillan, professor of physics, University of California, Berkeley, California; Walter J. Meek, acting dean, Medical School, University of Wisconsin, Madison, Wisconsin; J. L. Oncley, director, Ultracentrifuge Laboratory, Harvard University Medical School, Boston, Massachusetts; Lars Onsager, professor of chemistry, Yale University, New Haven, Conn.; John P. Peters, professor of medicine, Yale University, New Haven, Conn.; Paul A. Smith, professor of mathematics, Columbia University, New York City; C. Richard Soderberg, professor of applied mechanics, Massachusetts Institute of Technology, Cambridge, Massachusetts; Paul Weiss, professor of zoology, University of

Chicago, Chicago, Illinois; F. W. Went, professor of plant pathology, California Institute of Technology, Pasadena, California; Robert E. Wilson, chairman of Board of Directors, Standard Oil Company of Indiana, Chicago, Illinois; E. Bright Wilson, jun., professor of chemistry, Harvard University, Cambridge, Massachusetts.

Foreign Associates: P. A. Alexandroff, professor of mathematics, University of Moscow; K. Linderstrøm-Lang, head of the Chemical Division, Carlsberg Laboratory, Copenhagen; J. N. Brønsted, professor and director of the Institute for Physical Chemistry, Copenhagen; Björn Helland-Hansen, director of the Geophysical Institute, Bergen; F. C. Bartlett, director of the Psychological Laboratory and professor of experimental psychology, University of Cambridge.

Medal Awards

John J. Carty Medal. The John J. Carty Gold Medal and Award for 1947 was presented to Dr. Ross G. Harrison, professor emeritus, Osborn Zoological Laboratory, Yale University, New Haven, Connecticut, for the discovery that tissue cells can be grown outside the animal body, and by the use of this discovery demonstrating the manner of growth of nerve fibres, a fundamental contribution to scientific medicine and biology; for long and distinguished service as investigator, teacher, and counsellor of students; and for statesmanlike direction of the National Research Council during a period in which it played a vital part in the defence of the United States. As a young man at Johns Hopkins he obtained striking experimental results while engaged in the study of the development of the nervous system. Here he first used the method of isolation of embryonic tissues in culture media and gave an ocular demonstration that the nerve fibre grows out from a single cell without the participation of accessory cells. This led to the procedure known as tissue culture, which has since been widely used in the study of the differentiation, growth and behaviour of normal and tumour cells under various conditions outside the body. After retirement from active university work in 1938 Dr. Harrison became chairman of the National Research Council, which post he held until June 30, 1946. The Council has grown in esteem under his leadership, not as an organisational instrument merely, but also as a place where men gather in friendly association to advance common interests.

Provision for the Carty Medal and Award was made by the American Telephone and Telegraph Company in honour of the late John J. Carty, a member of the Academy, as a token of esteem on the occasion of his retirement from active service. Under the terms of the deed of establishment, the award can be made not more often than once in two years. It can be conferred on anyone who in the judgment of the National Academy of Sciences has made noteworthy contributions to the advancement of fundamental or applied science in any field.

Daniel Giraud Elliot Medal. The Daniel Giraud Elliot Medal for 1945 has been awarded to Dr. Sewall Wright, Department of Zoology, University of Chicago, for his fundamental work dealing with the genetics of evolutionary processes; a programme based on work over a long period, including his paper, "The Differential Equation of the Distribution of Gene Frequencies" (*Proc. Nat. Acad. Sci.*, 31, No. 12; 1945).

Public Welfare Medal. The Public Welfare Medal of the Marcellus Hartley Fund for 1947 has been awarded to Dr. Karl T. Compton, president of Massachusetts Institute of Technology, Cambridge, Massachusetts, for eminence in the application of science to the public welfare, in recognition of his distinguished contributions of an original character to the science of physics, of his long and valuable career in the field of education and of university administration, and of his great service to the Government of the United States both before and during the War as a member of the National Defense Research Committee and as director of the Office of Field Service of the Office of Scientific Research and Development. "It is the purpose of the Public Welfare Medal to mark the appreciation of the National Academy for eminent services to the public, performed without a view to great monetary gains and by methods which in the opinion of the Academy are truly scientific."

Agassiz Medal. The Agassiz Medal of the Murray Fund for the year 1947 was awarded to Felix Andries Vening Meinesz, professor of geodesy and geophysics in the University of Utrecht and president of the Netherlands Geodetic Commission.

Because of the instability of the water-soaked ground in the Netherlands it was not possible to make accurate measurements of gravity there with the older types of instruments. In order to overcome the difficulty Vening Meinesz designed his multiple-pendulum apparatus by which the desired measurements could be made on unstable ground. Prior to this invention attempts had been made to measure gravity at sea, notably by Hecker, but the results had errors ten times greater than was permissible in measurements made on land. As Vening Meinesz's apparatus could be used on a submarine it made possible gravimetric surveys of the different oceans. In 1923, with the help of the Netherlands navy, Vening Meinesz made his first long voyage, going from a home port to the Netherlands East Indies by way of Suez. In subsequent years he made many voyages in the Atlantic, Pacific, and Indian oceans, paying particular attention to the Mid-Atlantic Ridge and the West and East Indian island arcs. By the beginning of the Second World War, 844 observations had been made on Netherlands submarines, and many observations had been made on submarines of other countries. Among the interesting results of the gravimetric surveys was the discovery of strips of ocean bottom with negative anomalies, which in both the East and West Indies coincide with the seismic belts and the deep narrow troughs of those regions. The Mid-Atlantic Ridge is fundamentally different from the great island arcs in that in it there are no strips with negative anomalies. Two other generalizations are that fields of positive anomalies usually coincide with deep basins, and that the anomaly increases positively in going from shallow to deep water off both continental and island coasts.

Besides having made the measurements indicated above and having studied their distribution with reference to relief, seismic, and volcanic features, Vening Meinesz has proposed explanations of the processes operative in the formation of the troughs with the negative anomalies and the faults and folds in adjacent areas, a hypothesis for the explanation of the origin of the continents and ocean basins, and a hypothetical explanation of a postulated rotation of the earth's crust over deeper-seated material. The value of these unique researches in the study of the physical features of the ocean bottom and adjacent land areas is beyond estimate.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Teacher in the Mathematics and Physics Department—The Principal, Municipal Technical College, Hopwood Lane, Halifax (August 9).

Topographical Surveyors (4), Geologists (2), Biologists (2), and a Physicist, to the Falklands Islands Dependencies Survey—The Under-Secretary for the Colonies, Room 2, 3rd Floor, Queen Anne's Chambers, Dean Farrar Street, London, S.W.1 (August 9).

Graduate Assistant in the Department of Biochemistry—The Administrator, A.G.E. Sanctuary, Radcliffe Infirmary, Oxford (August 9).

Senior Principal Scientific Officer (with an Honours Degree, preferably in Mechanical Engineering), and a Principal Scientific Officer (with high Honours Degree in Physics), in the Royal Naval Scientific Service—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1941 (August 11).

Lecturer in Flight Experiments in the Department of Flight—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks (August 11).

Psychologist—The Director of Education, Education Offices, Cobourg Street, Plymouth (August 11).

Technical Chemist, and a Bacteriologist—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (August 15).

Assistant Lecturer in Physics—The Registrar, The University, Leeds 2 (August 15).

Assistant Lecturer in Mycology—The Registrar, The University, Manchester (August 16).

Lecturer in Crop Husbandry in the Department of Agriculture—The Secretary, The University, Edinburgh (August 17).

Senior Lecturer (Grade I) in Chemical Engineering, a Lecturer (Grade II) in Petroleum Production, and an Assistant Lecturer (Grade III) in Botany—The Secretary, The University, Edmund Street, Birmingham 3 (August 18).

Lecturer (temporary) in the Department of Electrical Engineering, University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (August 21).

Meteorological Officer Cadets (15) in the Department of Industry and Commerce—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (August 22).

Research Officer (Physical Chemist), Section of Tribophysics, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1314 (August 23).

Research Officer, Aerodynamics Section, Division of Aeronautics, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1319 (August 25).

Veterinary Inspectors (about 100) and Research Officers and Assistant Veterinary Investigation Officers (40)—The Secretary, Ministry of Agriculture and Fisheries, 23–25 Soho Square, London, W.1 (August 31).

Demonstrator in Anatomy, a Demonstrator in Physiology, a Demonstrator in Morbid Anatomy and Morbid Histology, a Lecturer in Anatomy, a Lecturer in Physiology, and a Lecturer in Biochemistry—The Secretary, Charing Cross Hospital Medical College, 62 Chandos Place, London, W.C.2 (August 31).

Technicians in the Departments of Anatomy and Physiology—The Secretary, Charing Cross Hospital Medical School, 62 Chandos Place, London, W.C.2 (August 31).

Principal Scientific Officer in the Intelligence Division of the Headquarters Office of the Department of Scientific and Industrial Research in London—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1951 (September 1).

Horticultural Officer, and an Assistant Horticultural Officer—The Chief Education Officer (A), Shire Hall, Cambridge (September 12).

Lecturer in Applied Chemistry, with qualifications to teach students taking an Honours Degree in Technical Chemistry—The Secretary, The University, Edinburgh (September 15).

Professor of Humanity in the United College, St. Andrews—The Secretary, The University, St. Andrews (September 15).

Graduate (in metallurgy, chemistry or physics) for work in a laboratory in the London area in connexion with the production of pure iron and associated research—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'London'.

Soil Technologist and Soil Chemist for the Directorate-General of Agriculture, Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.14628.

Lecturer in the Department of Physiology—The Secretary, The University, Aberdeen.

Workshop Mechanic in the Department of Physics—The Professor of Physics, Queen's University, Belfast.

Lecturer in the Mathematics Department—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Scientific Assistants (with honours degree in agriculture, botany, geography or biochemistry)—The Director, Imperial Bureau of Pastures and Field Crops, Penglais, Aberystwyth.

Laboratory Assistant with experience of histological technique—The Professor of Physiology, The University, Bristol 8.

Photographer for medical and scientific work—The Secretary, Physiology Department, School of Medicine, Leeds 2.

Bacteriologist for provincial diagnostic laboratory of public health in Halifax, Nova Scotia—Dr. E. G. Young, Lister Institute, Chelsea Bridge Road, London, S.W.1.

Assistant Experimental Officers (Chemists, male) in the Plant and Animal Products Department—The Establishment Officer, Imperial Institute, South Kensington, London, S.W.7.

Chair of Bacteriology in King Edward VII College of Medicine, Singapore—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Experts in (*a*) Preparation of Vaccines (M.N.18172), (*b*) Bacteriology (M.N.18173), (*c*) Animal Husbandry (M.N.18174), in the Veterinary Department, Government of Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting appropriate Ref. No.

Assistant Lecturer in Logic and Scientific Method—The Secretary, London School of Economics, Houghton Street, London, W.C.2.

University Assistantship in the Department of Biochemistry—The Secretary, The University, Edinburgh.

Laboratory Steward in the Chemistry Laboratories, and a Laboratory Steward in the Biology Laboratories—The Principal, County Technical College, Stoke Park, Guildford, Surrey.

Inspectors of Mines in Tanganyika Territory—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Professor of Pathology tenable at King's College, Newcastle-upon-Tyne—The Registrar, University of Durham, 46 North Bailey, Durham.

BRITISH COLONIAL DEVELOPMENT

THE announcement by Mr. Creech Jones in the House of Commons on June 25 of the Government's proposal to establish a Colonial Development Corporation marks a definite stage towards the establishment of a new Colonial system aimed at raising the standard of living in British Colonies, which has been implicit in such recent proposals as Dr. E. B. Worthington's Development Plan for Uganda, and the plan for the production of groundnuts in East Africa. The Ground-nut Corporation scheme is concerned primarily with foodstuffs; but its contribution to the raising of the standard of living in Tanganyika, Northern Rhodesia and Kenya may well far outshadow its contribution towards meeting the world shortage of fats. The twenty-five million pounds required for this Corporation is indeed to be provided separately; but it will none the less be as distinct a contribution to Colonial welfare as the capital of £100,000,000 of the Colonial Development Corporation now announced.

Mr. Creech Jones said that the Corporation would operate on commercial principles, and that its object would be to establish or assist any enterprise in the Colonies which is designed to increase their general productive capacity. While these enterprises might be mainly agricultural, the Corporation would be able to undertake any enterprise which served the general object either itself, or through subsidiary organisations for individual projects, or by assisting existing enterprises. Unlike the Development Board for the Colonies canvassed unofficially a few years ago, the new Corporation will be subordinate both to the Colonial Office and the Colonial Governments. The intention is that the Corporation and its subsidiaries should operate generally in close consultation with Colonial Governments, to ensure that their activities are conducted in the way best suited to promote the welfare of the Colonial peoples.

It was made clear that the Corporation is intended to supplement, not supplant, private enterprise. The Government would continue its policy of encouraging public utilities and other suitable forms of public enterprise; but it would also welcome private enterprise and investment so long as they are in harmony with the plans of Colonial Governments for social and economic development. Mr. Creech Jones, in reply to questions, indicated that the Government is alive to the importance of decentralization, and that although the head office must be in London, certain concerns and enterprises would have their principal offices in the territories with which they are strictly concerned.

The scheme as outlined by Mr. Creech Jones is thus based on the realization that capital on a far larger scale than is made available under the Colonial Development and Welfare Act is needed to raise the standard of living in the British Colonial Empire. What is equally important, there appears to be visualized co-operation with other Government departments besides the Colonial Office, such as the Board of Trade and the Ministry of Food. Several Departments are in fact already working together on a survey of opportunities for new commodity production in the Colonial Empire. Success may largely depend on the extent to which there is stimulated on a much larger scale that two-way flow of ideas, already to be seen on a modest scale, resulting from the work of the Colonial Research Committee and the Colonial Products Research Council. It will certainly depend largely on the extent to which there is secured the co-operation of scientific workers in the way that is so conspicuously a feature both of the ground-nuts project for East Africa and the development plan advanced by Dr. E. B. Worthington for Uganda*. The feature of Dr. Worthington's plan is the suggestion that pilot development schemes should be used to try out ideas of land use and social services which later can be applied to large parts of the Protectorate. They should also be areas of intensive production, at first by State enterprise, in country which is at present largely undeveloped. In this way, Dr. Worthington contends, about twice as much expenditure on public services per head of population as is possible in the country as a whole will pay dividends after ten years.

Dr. Worthington recognizes and states the fundamental problem in Colonial development and welfare which the general schemes under the new Corporation will equally have to face. The average standard of living cannot rise and public services cannot expand unless production increases at a greater rate than population. Ten years, he suggests, should be devoted to a production drive while increasing social services at a rate greater than population increase. If success is achieved, Uganda will be able to support mass education and a mass health scheme during the following decennium.

In the production drive, the great asset of Uganda is not man-power but undeveloped land and water. The chief factors which limit development are the lack of fundamental formation about the country and the people ; a system of production incompatible with the full use of natural resources ; lack of capacity of the African for physical work ; and power based on the most inefficient of fuels. Dr. Worthington's plan aims at solving the fundamental problem of balance between population and production by reducing these limiting factors, although he is doubtful whether adequate results can be achieved without some degree of compulsion, possibly the equivalent of that which is applied in Britain to-day.

The pilot schemes suggested are for the development of a self-contained piece of land, preferably a catchment area of say 500 square miles, sparsely inhabited on account of tsetse fly. Settlers up to 6,000 families would be employed for the first few years, while the whole area was being developed as a Government estate. At this stage there would be only six Europeans as against 42 Europeans to about 1,800 Africans in the resident units of the ground-nut scheme. Later, most of the settlers would become tenant farmers under close supervision, a part of the unit being retained as a Government farm. Initial clearing and subsequent cultivation would be undertaken with mechanical assistance, where possible. Communications, forestry, water-control, agriculture, fisheries and social services would be organised for the efficient development of land, water and people, with an emphasis on productive services.

The scheme is finely conceived and represents a scientific approach that might well be adopted more widely. It is not only in research in applied biology, in animal husbandry, forestry, fisheries, hydrology, meteorology, agriculture and the like that science can contribute so much to Colonial development and welfare. It is becoming more and more clear that the scientific approach is the only one that holds out real hope of a solution to the all-important human problem. Although Dr. Worthington makes like reference to the contribution of the social sciences, his scheme, like the ground-nut scheme, is in keeping with the idea that Mr. Aldous Huxley outlines in his recent book, "Science, Liberty and Peace"*, of developing regional self-sufficiency as a decentralizing and stabilizing factor in world order. It is equally in line with ideas which Col. W. R. Crocker emphasizes in his penetrating commentary†, "On Governing Colonies", of concentrating less on what is ideal from the European point of view and more on what is practical from that of the African, on the preventive rather than the remedial aspect of public health and the essential idea of the Tennessee Valley Authority, in which the association of the ordinary people affected by the scheme is first secured. Similar ideas are stressed by Sir J. Hawthorn Hall, the Governor of Uganda, in some notes on the economic development of Uganda which preface Dr. Worthington's report.

That the regional aspect is present in the mind of the Colonial Secretary is shown by his recent comments on the eighteen months work of the Colonial Economic and Development Council. Nearly all the thirty-five territories concerned have submitted ten-year development plans, although some plans have been referred back with comments or suggestions. But Mr. Creech Jones has stressed the importance of regional planning and development in contiguous Colonial territories such as East, Central and West Africa, and also in the West Indies. In a memorandum accompanying his dispatch of February 14, 1947, on closer association of the British West Indian Colonies, he refers to the manifest need in all the Colonies concerned for improved facilities for research, including surveys and statistical services, in order that plans for economic development and social welfare may be soundly conceived and wisely executed. Except in co-operation, the Colonies will not generally be able to afford or fully to employ the services of the experts required to fulfil those functions. It was announced in this dispatch (Cmd. 7120. H.M. Stationery Office, May 1947. 9*d*. net) that a conference is to be held at Montego Bay, Jamaica, in September, and its outcome will be watched with great interest by all who are aware of the potentialities which have already been revealed in the Caribbean.

There are other aspects of the man-power situation which are of fundamental importance in all these proposals. Inevitably the formation of a Colonial Development Corporation, like the Ground-nut Corporation, with its various subsidiary schemes and ramifications, tends to widen the range of opportunities which the Colonial Service offers and to call for more varied abilities among the members of that service. No thoughtful reader of Col. Crocker's recent comparative study of British, French, Belgian and other Colonial practice and experience can doubt the need for recruits of high quality to the Colonial Service, the great scope for initiative and responsibility which that service offers, or the need for a new outlook in some quarters and for drastic changes in organisation, practice and the transfer and promotion of staff. Ultimately, it is on the quality of the staff by which the Development and Welfare Schemes are administered, their vision and understanding of the needs and minds of the native peoples, their appreciation of the contribution of science, of the problems and opportunities of the private and public corporations seeking to serve the needs of the native peoples and of the world, that success will depend. Nor will the ablest men and women be forthcoming and their zeal and enthusiasm maintained unimpaired unless the conditions of service are such as to call forth their best efforts and to give them the continued stimulus and incentive that will spring from manifest participation in the high task not merely of serving the material and social needs of the Colonial peoples, but even more of training, inspiring and guiding their future leaders in accordance with those new conceptions of imperial responsibility which mark the third Colonial Empire now developing. It should be a first pre-occupation of the Government to see that no timidities or inhibitions of Colonial administration are allowed to hinder the full use of all the expert knowledge of Colonial resources and methods of treatment that have been accumulating in the last four years, or the vigorous prosecution of the fresh researches still required. Above all, nothing must be allowed to frustrate the boldness of imagination with which these new opportunities must be served.

CHEMICAL CRYSTALLOGRAPHY

Chemical Crystallography

An Introduction to Optical and X-ray Methods. By C. W. Bunn. Pp. xii+422+13 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1945.) 25s. net.

PROF. VICTOR GOLDSCHMIDT used to say that, over the door of his laboratory in Heidelberg, he would like to have written "Die Kristallographie ist die Königin des Wissenschaften"; and while he said this chiefly because he personally was fascinated by the external shapes of crystals and their formal geometry, he may perhaps also have thought of crystallography as holding a distinctive place among the sciences, at once isolated and yet pervading. Indeed, crystallography as we know it to-day is in many ways a curious subject. It has come to be principally concerned with the use of X-ray diffraction effects to study, to varying degrees of precision, the arrangement of the atoms in substances, many of which can scarcely be called crystalline at all. The techniques employed belong largely to mathematics and physics, and the information derived is of fundamental importance to subjects so far apart as metallurgy and biology, and particularly to chemistry. There seems, perhaps, something unsatisfactory in the way we cling to so precise a term as 'crystallography' to cover all these developments. Yet, as the combined international body of 'crystallographers' discovered in recent discussions, it is difficult to find any other term to which we can give all the meanings we associate now with the word 'crystallography'.

There is more than one reason for this situation. Without the early classification of the geometrical form of crystals and the mathematical developments of space-group theory, the problem of structure analysis by physical methods is at least much more difficult. Far more of the kind of exact data on which most interest centres—the details of the arrangement of atoms in space and the exact distances between them—can be got once a really crystalline substance is available (some justification for all the hours that have been spent in chemical research in the preparation of 'a crystalline derivative'). But the apparently complex background of knowledge, mathematical, physical and crystallographic, which is required for the proper use of X-ray analysis, makes the subject too often seem too difficult just to those who should find its applications most useful, and particularly to students and research workers in chemistry.

It is the great merit of Mr. Bunn's book that it does very largely attempt to develop a new approach to the study of crystallographic methods based on the use in chemical research of a variety of ways of observing crystals and their structure, both new and old. This new approach is extremely practical. It is designed to meet the needs of those who wish to know, in the first place, what types of chemical information can be gained by using crystallographic methods, and secondly, the essential practical and theoretical details necessary for operating these methods. The relations between these different aspects of the subject are outlined in a very clear general survey of the field which forms the opening section of his "Chemical Crystallography". This survey indicates the limitations as well as the applications of X-ray methods; it also describes the general division of the subject-matter of the book into different, more specialized sections.

The primary purpose in chemical research of getting a 'crystalline derivative' is usually for the identification of different chemical individuals. The assistance which can be given in this direction by crystallographic techniques, particularly crystal morphology and optics and X-ray powder photographs, forms the subject of the first major division of the book. Around this theme is developed the necessary formal information on the types of crystal symmetry possible, on the examination of optic figures and the measurement of refractive indices, and also elementary theory of X-ray diffraction. Here there are important contributions to the presentation of the subject as a whole. For example, the indexing of crystal faces is notoriously difficult for the non-specialist to appreciate. Mr. Bunn begins by showing excellent photographs of crystals growing, and leads by easy stages through the relation of the observed crystal layers to the packing of atoms in space, and so to a derivation of indices for the crystal faces which seems both natural and simple. Further, this derivation presents the indexing process in a way which is very helpful in the later consideration of X-ray analysis.

The second part of the book is devoted to structure determination. It covers both the experimental methods of X-ray photography, the indexing of the more important varieties of photographs, and the actual processes of deduction of the atomic positions from the experimental observations. The methods are illustrated by a section which gives a variety of examples of actual structure determinations carried out both on inorganic and organic substances, and also on certain types of imperfectly crystalline material, for example, long-chain polymers. The use of Fourier series, both in the determination and refinement of structures, is (rather briefly) described. Crystallography is, like all good sciences, also an art, and the methods of practising it differ in the hands of different investigators. One realizes in the course of these chapters not only the variety of the problems of structure analysis, but also something of Mr. Bunn's own position as a successful 'artist' with his own particular approach to these general problems. His own technical contributions in this field are already having considerable effect on the general strategy of X-ray analysis, particularly his practical development of Bragg's optical diffraction method, which is here for the first time fully described. The section concludes on quite different topics, the bearing of crystallographic research on what has been termed the 'texture' of materials, the calculation of particle size from broadening of X-ray lines, and the determination of strain.

I suppose it would be impossible for any book to cover so wide a field as this in a new and individual way without leaving openings for criticism. It seems rather unnatural, for example, to describe powder photography before single-crystal photography. Certain sections seem really too short for maximum usefulness; for example, that on crystal structure and physical properties. There are also a few misprints in the book (for example, the formula on p. 158), and one section at least, that on rhombohedral lattices, p. 135, which is quite misleading. But almost immediately, arguments arise in defence at least of Mr. Bunn's general treatment. There are definite practical advantages in the association of powder photography with other methods of crystal identification; and any great lengthening of an individual section would certainly detract from the usefulness of the book as a readable and coherent survey of the field as a whole. The serious student of the subject has, sooner or later, to turn to original papers, and for this purpose excellent references are supplied.

Taken all together, this book is most welcome. It is very clear and easy to understand, and also beautifully and plentifully illustrated. It has already proved its value in crystallographic teaching and practice, and should play an important part in the development of the subject as one of the established tools of chemical research in the widest sense. But while Bunn's "Chemical Crystallography" is certainly a book that has been badly needed, it may perhaps be fair to add that it is not the only badly needed book on the subject of crystallography to-day. Many of the chapters here could usefully be enlarged into monographs or even text-books. It is to be hoped that some at least of these books are in process of construction.

D. Crowfoot

EXPANSIONS IN EIGENFUNCTIONS

Eigenfunction Expansions associated with Second-Order Differential Equations

By Prof. E. C. Titchmarsh. Pp. vii + 176. (Oxford: Clarendon Press; London: Oxford University Press, 1946.) 20*s*. net.

The subject of Prof. Titchmarsh's book is the expansion of an arbitrary function in terms of the eigenfunctions of linear differential equations; to be precise, in terms of functions which satisfy an equation of the form

$$\frac{d^2y}{dx^2} - q(x)y + \lambda y = 0. \qquad (1)$$

Problems of this nature arise in the theory of vibrations of elastic media, where we wish to express an arbitrary vibration in terms of the stationary vibrations: here the corresponding equations are the classical Sturm–Liouville equations. During this century, similar problems have become important in connexion with the Schrödinger equation of quantum mechanics; the physical problem corresponding to the mathematical problem of the expansion of an arbitrary function is the expression of an arbitrary state of a system in terms of the eigenstates of an observable. The corresponding differential equations are of singular type; that is, the interval involved is infinite, or the function $q(x)$ becomes infinite at the ends of the interval.

Prof. Titchmarsh has devoted most of his attention to the singular case for an infinite interval. The ordinary Sturm–Liouville problem is dealt with briefly in one of the early chapters. The rest of the book is devoted mainly to the consideration of the nature of the spectrum, that is, roughly speaking, of the set of values of λ for which the equation (1) has solutions, and to the convergence of the resulting expansions for arbitrary functions. In many cases the spectrum consists of isolated points, and the resulting expansion is a series similar to a Fourier series; in other cases the spectrum consists of all the points of an interval and the expansion is an integral, similar to a Fourier integral; in other cases, of which the Schrödinger equation for a hydrogen atom is a notable example, there is a combination of both types. A very interesting chapter shows how these different cases result from different types of behaviour of $q(x)$ as x tends to infinity.

Another important problem is the distribution of the eigenvalues, or of the size of the n^{th} eigenvalue when the eigenvalues are arranged in order of magnitude. Results are given for this in which the semi-intuitive arguments of physicists are replaced by rigorous analysis.

The greater part of the book is devoted to the convergence or summability of the expansions. These have in the past been treated in the general case almost exclusively from the point of view of convergence in mean square, and results for ordinary convergence or summability at a point have been obtained in the main only for particular cases. Prof. Titchmarsh gives results for the convergence of these expansions when the function $q(x)$ obeys certain sets of conditions which hold in the important particular cases; and he shows that under wider conditions the series expansion is summable to the function represented: this function must obey the same conditions as are necessary for the convergence or summability of a Fourier series.

In the past these problems have been treated either on the basis of the theory of integral equations or the theory of linear operators in Hilbert space. Prof. Titchmarsh has used the theory of functions of a complex variable, and makes no appeal to the methods mentioned. His method is to express the solution of the equation as a contour integral and then to get his results directly by the powerful methods of contour integration. The earlier treatments are perhaps more suitable for a discussion of mean square convergence, or for unifying the theory with that of integral equations and other linear operators, but are certainly more difficult to apply to the study of the problems here treated.

The book has the lucidity and mastery of analytical method which characterize the author's well-known books on the "Theory of Functions" and "Fourier Integrals"; but unlike these it gives not an exposition *ab initio* of the subject as a whole but only of results and methods for the problems mentioned above, which were very largely developed by Prof. Titchmarsh in his recent papers on the subject. It does not attempt an account of the physical background of the subject. All the important special cases are dealt with as examples, but without detailed accounts of the special functions involved which are dealt with in the standard treatises on differential equations. However, a reader with a knowledge of complex variable theory should be able to follow the analysis. As a whole, the book is an important contribution to analysis, and should prove of interest to mathematical physicists as well as to mathematicians.

NAMES INTO CIPHER

A New Notation and Enumeration System for Organic Compounds

By Dr. G. Malcolm Dyson. Pp. iv + 63. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1947.) 7*s.* 6*d.* net.

WHAT Dr. Dyson has given us in this volume is less a book on nomenclature than a 'blueprint' or a code manual for the professional indexer. Although the system of notation which he describes demands, and indeed merits, careful scrutiny and examination by organic chemists who are specialists in different fields, it can scarcely be regarded as a contribution to the problem of organic chemical nomenclature properly understood, and the ordinary organic chemist will find what he requires in Dr. Dyson's original lecture last October as since published by the Royal Institute of Chemistry rather than in the present book. The major part of the book is devoted to a careful and detailed exposition of Dr. Dyson's system of ciphering, in which the basic carbon skeleton is first ciphered by a linear series of letters and numerals, with the assistance of commas, stops and semi-colons. All fused-ring systems are enumerated in terms of six conventional ring systems. The functional groups are then similarly ciphered, and the system is logical as well as ingenious and concise. Dr. Dyson claims, moreover, that it has the advantage that there is only one possible cipher for any one chemical compound.

That is an impressive claim, and has to be weighed carefully against any doubts one might entertain as to the unfailing accuracy with which the ordinary organic chemist would apply the rules in practice; and equally, his unerring eye not merely for departures from the logical application of the rules but also for mechanical errors in the transcription of the cipher. An error in nomenclature is usually self-evident to an expert in a particular field, but this is scarcely true to the same extent of a cipher or indeed of a number; and that is probably one reason why the Universal Decimal Classification is unlikely ever to be adopted as a working tool in the indexing of organic chemical compounds.

Dr. Dyson appears, in fact, to have dismissed this question of nomenclature too summarily, and what he has to say under this head is much better put in his original lecture. He does not here show sufficient apprehension of the purposes of nomenclature, or of those relations between its users which are responsible alike for the introduction of trivial names and for departures from systems. Granting that such names as 'coronene', 'phthalazine', or 'rubicene' have been coined because there are no satisfactory systematic alternatives, regarded as symbols, for certain purposes, they may prove as satisfactory as the ciphers suggested by Dr. Dyson. It must be remembered that in particular fields, such as dyestuffs, or synthetic resins or other plastics, the organic chemist will think in the units of which the structure is built up: no dyestuff chemist would attempt to use the systematic name for dianisidine blue, any more than the plastics chemist would trouble with a systematic name for nylon. The trivial or systematic names of the substances brought together in practice in these complex molecules serve the needs of the chemist, even when he is accustomed to use the punched card technique as a regular tool.

The point has been elaborated because the future of the Dyson notation, once its logic and adequacy have been approved in a representative range of special fields, appears to depend on the use to which it is likely to be put. For the reason just given, its adoption by the industrial chemist is unlikely; and when we turn to consider its potentialities in regard to the production of a new lexicon of organic chemistry, a new 'Beilstein', or international indexing and abstracting, it should also be remembered that the present situation is unsatisfactory not only through confusion between different systems of nomenclature and failure to agree, but also for financial reasons. Empirical formulæ, for example, apart from the possible use of the Universal Decimal Classification, already provide a basis for such production if the necessary financial means to the end were willed. That financial aspect needs to be much more carefully examined before any decision is reached, or we may be in danger of finding that Dr. Dyson has prescribed a sledge-hammer to crush a nut.

Despite the ingenuity and logic of Dr. Dyson's notation, in this volume he appears to have missed an opportunity. He should have dealt much more persuasively with established systems of nomenclature, as he did in his original lecture, before proceeding to detail the new notation. A little more trouble in exposition of these systems and of present tendencies would have assisted him considerably to gain acceptance for his idea that a cipher rather than a systematic name is the best means for reference, classification and indexing. Finally, it might be observed that in production the volume compares badly with the lecture issued by the Royal Institute of Chemistry. Neither paper nor print are up to that standard, and to issue unbound at this price a volume which obviously demands close study and constant use is a serious defect.

R. BRIGHTMAN

WATER SUPPLY AND BIOLOGY*

By Prof. W. H. PEARSALL, F.R.S.

University College, London

WATER supply undertakings are primarily concerned with the production of an adequate supply of water of purity suitable for human and industrial consumption. Three features require attention. For human consumption it is of prime importance that the water must be free from deleterious substances and from disease-causing organisms. Secondly, for any purpose, uniformity of quality is a great virtue, and the quality must be such as to include freedom from unpleasant tastes or smells as well as from the more noticeable forms of chemical contamination. (We may leave on one side the question of the suitability of certain types of water for particular industrial uses.) Thirdly, the volume of water required is becoming an increasingly important factor in the problems of supply.

Great Britain has long enjoyed the provision of an admirable water supply. This is now taken for granted, and its advantages are so rarely realized that little credit is given to those responsible. We owe it primarily to the labours of the Rivers Pollution Commission in the 1850's and 60's.

The problem at that time was associated with a series of epidemics of typhoid fever and dysentery. It had been recognized that these were probably water-borne diseases, although due to germs which were excreted in human fæces. All water supplies which could be contaminated by human or animal excretions might thus be suspect, and the Rivers Pollution Commission was called on to investigate the matter and to survey the water resources of the country from this point of view.

They tackled the problem mainly by chemical methods, making use of the fact that animal organic matter is rich in nitrogen, a feature in which it contrasts markedly with plant materials. Thus in the former case the organic C/organic N ratio is low—and this is, in practice, coupled with a high rate of transformation of the material by bacteria to oxidized and inorganic forms of nitrogen-like nitrates. Two chemical features thus make a water suspicious from this point of view—a high nitrogen content and the presence of organic matter with a low C/N ratio.

I mention these activities of the Rivers Pollution Committee because their appreciations and methods were far in advance of their time, and 60–70 years were to elapse before it was generally realized that their technique for describing the origin and breakdown of organic matter was a fundamental one.

The attack on the problem of contamination by fæcal matter led also to the recognition of the fact that almost all surface waters were potentially dangerous. No better illustration of this fact can be given than what happened in Glasgow. There, in 1859, a public water supply from Loch Katrine replaced the numerous shallow wells that had formerly been used. Prior to 1859 a series of three typhoid epidemics had each resulted in the loss of more than two thousand lives. In epidemics, after that date, the number of lives lost fell to about one hundredth of the former number, and in all cases the infection was found to be associated with the continued use of the original supply from shallow wells.

The chemical methods formerly used for determining the character of water supplies have gradually been supplemented and largely replaced by biological methods. These make use of the fact that animal excreta constantly contain certain bacteria which survive for a time in water; but are unable to multiply materially under natural conditions. Particularly useful in this respect are forms like *Bact. coli.* and *B. welchii.* Thus use is now made of the presence or absence of such organisms under prescribed trial conditions to test for the freedom of the water examined from possibly dangerous contamination. To these testing methods have been added the use of bactericidal treatments, which have reduced the dangers from water-borne disease bacteria to vanishing point. Under modern conditions even isolated cases of typhoid fever or of other water-borne diseases are almost unknown, and they cause great consternation when they occur, as in the case of the Croydon epidemic just before the War. The freedom from such epidemics is due to the efficient methods of treatment and bacteriological control now employed.

The most recent developments in water supply problems are also associated with biological matters. Many of the difficulties in the way of efficient water-supply result from the large volumes required. These have risen steadily not only owing to improved methods and standards of sanitation but also to the development of industrial processes with a high water requirement. The aggregation of population in industrial Britain has greatly exaggerated the tendency, and it is becoming increasingly difficult to envisage the continuation of the present conditions without some system of overall planning, for all the larger centres of population must import water from a distance.

It is not, perhaps, generally realized that, in many rural areas also, existing population nearly or quite suffice to use all available supplies. In some areas, Derbyshire for example, no further increase in the rural population is possible. The difficulties in the way of obtaining adequate volumes of water have various effects. In southern England it has long been necessary to use river waters always more or less contaminated by sewage and by manurial treatments on the agricultural country through which they flow. It is only possible to use these waters safely because of the great improvements in bactericidal treatment and control now available.

The maximum amount of water available in any one place is the difference between the amount falling as rain and that evaporated back to the air. It is usually equivalent to about 10–12 inches of rain per annum in southern England. Rainfall is seasonal, so that it must be stored until required in the summer. The storage can be natural, underground stores as in the case of porous rock strata like chalk or limestone. The alternative is to utilize impounding reservoirs, and because these offer a habitat for plants and animals to grow in, many of the biological problems of water supply centre around the control of impounding reservoirs.

The organisms that appear may impart unsuitable quality or unpleasant tastes and smells to the water; but even if they do not, their presence necessitates filtration, and the quantities that at times must be removed add greatly to the difficulties of the water engineer. The algæ are the principal offenders in this respect, particularly diatoms and blue-green algæ. Some indication of the magnitude that the problems of filtration may assume may be gleaned by the following example, illustrative particularly of conditions near London. A reservoir receiving water from the Thames and containing about 7 thousand million gallons might contain at times 110 tons of a single alga, *Fragilaria crotonensis*, measured as dry matter, and roughly a thousand tons as live algæ. From the volume of water normally filtered this involves a daily removal of at least a ton of dry weight, roughly equivalent to at least 10 tons of living alga.

---

*From a Chadwick Public Lecture delivered in the Chelsea Physic Garden on June 19.

It will be realized, then, that during periods of abundant algal growth, the algæ alone greatly complicate the problems of a waterworks engineer, for rapid replacement of filters becomes essential. Similar problems are sometimes presented by other aquatic organisms, notably the Cladocera or water fleas. However, the algæ and other aquatic plants have an especially important role because they are the producers of organic matter in fresh water, utilizing light energy and dissolved salts in building up new organic materials. As a general rule the abundance of sub-aqueous life is correlated both with the abundance of algæ and also with the amounts of certain mineral nutrients which are likely to limit their growth. The concentrations of bicarbonates, of nitrates and of phosphates are particularly important in this respect; but in some cases, as in some of the English Lakes, the continued growth of the diatom, *Asterionella*, is apparently limited by depletion of silica, which must exceed a concentration of 0·5 parts per million. There is also some evidence that the presence of high proportions of blue-green algæ in a water can be correlated with an abundance of dissolved organic matter.

Although there are many gaps in our knowledge of the factors which make for algal abundance, it is quite clear that as a general rule certain algal types are indicative of certain water conditions. It is known, for example, that the course of recovery from organic pollution in a stream can be traced by the sequence of algæ found below the pollution source. The influence of the dissolved salts on the algal flora is equally evident in unpolluted waters. In mountain regions, as in some Connemara lakes studied, the different floras characterize the more calcareous waters, and there are distinct elements indicative of peaty waters; while it was long ago noticed by Dr. G. S. West that the faintest traces of pollution by animal fæcal matter results in an abundance of diatoms. In fact, the organic life of a body of water is far more sensitive to traces of pollution than is usually supposed. The biological character of a piece of water depends so much on salts like nitrates and phosphates, the oxidized products of organic matter, that even traces of a completely oxidized sewage effluent usually suffice to change the flora and fauna qualitatively, and they will certainly enrich it quantitatively.

It follows from these facts that the biological analysis of the algal flora is capable of giving information of great value as to the quality of a water supply. At the same time, the recognition of the importance of the reservoir as a biological system would do much to simplify the water engineer's problems, and it may be useful to outline the problem from this point of view. Any deep body of water consists of two depth zones, an illuminated zone producing algæ and organic matter and well aerated as a result of photosynthesis, and a deep zone in which organic matter is broken down and oxygen is consumed. The rate of the latter processes is normally highest at the surface of the bottom mud, and consequently, as the temperature rises, the mud and the water above it may become devoid of oxygen or *anaerobic* whenever there is a large supply of organic matter. Under anaerobic conditions, nutrient salts rapidly diffuse from the mud to the water, ultimately to become available once more for plant growth in the surface layers of the water. If, however, conditions remain such as to maintain a higher oxygen supply at the mud surface, little or no diffusion of nutrient salts to the supernatant water is possible. The development of anaerobic conditions at the mud surface thus greatly increases the rate of circulation of plant nutrients, and especially the size of the vernal algal phase. The matter has a considerable bearing both on reservoir design and filtration difficulties.

It seems clear that the reservoir form ought to be one of low surface volume ratio designed to avoid oxygen deficiency in the lower layers, with an oxygen reserve sufficiently large to give a margin over the summer oxygen consumption, while the small surface should allow comparatively little production in the surface layers. Pertinent data here would presumably be obtained from estimates of the 'biological oxygen demand' and the potential algal or zooplankton production.

The development of oxygen deficiency in the deeper waters of a reservoir has direct effects on the water quality, as well as the indirect ones which result finally in greater algal production. One of these is that ferrous iron compounds appear in solution. These are at some later stage oxidized and redeposited in the ferric state, often in the pipes of the supply system. The processes involved are catalysed by certain iron bacteria, and they not only lead to the blocking of supply pipes but also to the unsightly staining of bathroom furniture.

Equally common under these conditions of oxygen deficiency is the presence of hydrogen sulphides or of other metallic sulphides, with particularly unpleasant smells. These cause great trouble in some calcareous waters containing much organic matter, and they have been a particular source of trouble in the filter beds of tropical and sub-tropical regions.

It is evident, from whatever angle it is approached, an important biological problem in water-works is that of reducing production. In southern and eastern England, where the drainage water is mainly from fertile land, the water works engineer must, if surface water is to be used, resign himself to the need for filtering off large quantities of algal and other organic material. In this case, topography and the need for bacteriological and chemical control of the product usually prevents even an approach to the ideal in reservoir form, while the use of the drainage area for agriculture prevents any attempt to sterilize it or reduce the productivity of the inflowing waters. It can be asked of the freshwater biologist that he forecasts the probable periods of greatest load in the filtering plant, a possibility dependent upon the recognition and maintenance of a seasonal rhythm in algal growth as well as an increased knowledge of the physiology of the organism concerned.

It is, however, also reasonable to inquire whether these steps wholly exhaust the possibilities. A profitable line of inquiry would be to consider whether the intensity of production at peak periods could be reduced and spread out over a longer period or diverted into other channels.

A reduction in algal growths has usually been brought about by the use of algicides, of which copper sulphate is most popular. There is some justification for employing such methods to retard algal growth, but little or none, other than dire necessity, for using them to destroy heavy growths, for the result is almost certainly to result in overtaxing the oxidizing agencies in the reservoir or filtration system, leading to the establishment of anaerobic conditions. In practice, moreover, copper sulphate is known to have other disadvantages; one of them is that more resistant algæ replace the earlier growths, and in some cases these are small enough to pass through filters. A second disadvantage is that there is an increase in the sulphur content of the bottom mud, and when oxygen deficiency develops, the bottom water acquires a high concentration of sulphides. To this agency, also, has been ascribed the later appearance, in some quantity, of sulphur bacteria.

Particularly striking effects are due to these organisms when they are pigmented forms such as *Rhodococcus*, which at times may colour water pink.

From the point of view of water supply, north-western Britain has the great advantage of being an area of high rainfall, of mountain and moorland, and of soils and water of low fertility. The control of reservoirs in such an area presents quite a different series of problems. The first of these is that though the initial fertility of a water is almost always low, yet it is already known that after 30–50 years reservoirs have developed algal production to a high degree. This falls in line with the discovery that certain of the English lakes are accumulating nutrients (nitrogenous materials, for example). In summer more nitrogen enters the lake by the inflows than goes out down the outflow, and it seems that this state of affairs must be not infrequent. Moreover, in winter, the amount of available nitrogen (for example, nitrates) in a natural water is generally at a maximum. If we store this water instead of allowing it to escape to the sea we are, in effect, putting a trap for plant nutrients into the system, so that the annual production is in any case likely to rise.

It seems clear, therefore, that any measure which will tend to reduce fertility in these waters will be valuable. Even if it were only possible to remove a small percentage of the circulating nitrogen and phosphorus, for example, it might suffice to remove the annual accumulations in the lake system.

The question of how to remove part of the annual crops of organic matter becomes a very important one in this particular instance. The obvious way of cropping a reservoir and of obtaining some financial return for the labour involved is to take a crop of fish or of some other cash product from it. The annual crop should equal the annual gains of nitrogen, for example, or else should help dissipate it. From the point of view of the economy of the country as a whole, indeed, the whole of the valuable nitrogenous compounds could profitably be removed from the water. What are the conditions and limitations of this ideal? In effect, the production of organic matter in water passes along a series of food chains—starting generally from algæ, passing by various stages, such as plankton, molluscs and insect larvæ, for example, into fish. Now in each of these steps there is a considerable loss of production. To take a more familiar example, a mature sheep has eaten about ten times its own weight during its growth and development. Thus if this sort of difference is usual, a food chain, containing four steps: *a* (algæ), *b* (insects), *c* (small fish), *d* (larger fish), would give relative productions as percentages of the initial production mechanism of:

(*a*) 100, (*b*) 10, (*c*) 1, and (*d*) 0·1.

(It is, however, perhaps likely that the ratio of weight of food to weight produced is less than that used; about 5 to 1 has been suggested for freshwater creatures.) Generally speaking, water-works practice does not favour fish production in their impounding reservoirs, and to this extent it limits the possible food chains. Clearly, also, the method of operation collects the primary producers (algæ), and so has to deal with the largest weights, though at the same time it probably removes the largest amounts of carbon and nitrogen. However, the algal maxima are short-lived, and it would be advantageous to be able to crop at any time. This means using long-lived creatures for crop-taking.

In contrast, those interested in fish production may obtain higher yields by the shortening of the food chains. It would, for example, greatly increase the yield if, say, the fish (*c*) could be taken rather than another piscivorous fish (*d*); and better still, herbivorous species of fish should give higher production than any carnivorous species.

The piscicultural and the water-works problems are thus both different aspects of one which has equally important bearings on our natural economy to-day—for in these lean times, we are deeply concerned with obtaining the maximum yield from our diminishing acres. It may, therefore, be interesting to collect data comparing the productivity of water and of land in comparable terms.

Yields in lb. per acre

Land: Meat only, 190.
Wheat, 1,800–2,000*.
Beet (as sugar), 3,000*.

* Approximately equivalent to *dry* weight.

Water: Thames water—*c*. 1,400–2,000* maximum algal.
Lake Mendota—Total plankton, *c*. 10,000*.
Algæ in water, say, 6,000*.
Submerged shore-weeds, 1,500–1,800*.

* Dry weight.

Fish: 6– 10, Alpine lakes.
170–180, Illinois river.
180–200, carp ponds (manured).

The estimates for Lake Mendota plankton assume that it is renewed weekly. I think this may be two or three times too often. The data for average dry weight of green plants on the shores of this lake suggest that algal production in the plankton might be 2–3,000 lb. per acre as dry weight, a somewhat similar figure to the estimate for vernal production in Thames water.

It will be seen that the productivity of fertile waters approaches that of the fertile lands from which they drain and the richness of which they contain. From the point of view of conserving natural resources there is much to be said for exploiting the reserves of nitrogen and phosphorus which are otherwise being washed away to the sea. It may be that when we use fertile surface waters for water supply purposes, some system of preliminary crop-taking might be introduced—shallow reservoirs the bottom mud of which could be often removed, or used for a system of water-meadows or for fish-cropping. At any rate, it seems that the desirable biological control of water resources involves consideration of these matters.

TOXIC PROPERTIES OF ω-FLUOROCARBOXYLIC ACIDS AND DERIVATIVES

By Dr. B. C. SAUNDERS
University Chemical Laboratory, Cambridge

We have already reported[1] upon the highly toxic nature of fluoroacetic acid, FCH_2COOH, and its derivatives. The present communication gives an account of further work on the toxicity of allied compounds. The earlier part of the present investigation was carried out under the ægis of the Ministry of Supply during the War, and reports were submitted to that Ministry from time to time and were made available to American workers. The more recent parts of the work have been sponsored by the Imperial Chemical Industries, Ltd. (General Chemicals, Widnes). We are grateful, therefore, to the Chief Scientist, Ministry of Supply, for permission to publish the details of the reports to the Ministry of Supply, and to Imperial Chemical Industries, Ltd., for grants which have enabled us to continue the work.

Methyl fluoroacetate[1,2] was shown to be a convulsant poison and highly toxic by inhalation and by injection; the L.D. 50 for subcutaneous injection into mice being of the order of 7 mgm./kgm., and the figure for intravenous injection into rabbits being 0·25 mgm./kgm. The toxicity figures for fluoroacetic acid were of the same order, and the symptoms produced by the free acid were identical with those produced by the methyl ester.

We then demonstrated that a large variety of derivatives of fluoroacetic acid exhibited the same order of toxicity as that shown by the acid itself. For example, $FCH_2COOC_2H_5$, $FCH_2CONHCH_3$, and $(FCH_2CO)_2O$ were almost equally toxic. Fluoroethyl alcohol, FCH_2CH_2OH, and the aldehyde, FCH_2CHO, were also of the same order of toxicity, whereas fluorochloroethane, FCH_2CH_2Cl, was non-toxic. These results indicated that a compound which could give rise to fluoroacetic acid either by hydrolysis or oxidation was toxic[3]. In other words, the toxic principle appeared to be fluoroacetic acid, or the fluoroacetate ion.

American workers[4] reported that esters of 2-fluoropropionic acid, FCH_2CH_2COOH, were non-toxic, and that esters of 3-fluorobutyric acid were toxic. In June 1944 we announced[5,6] that we had synthesized ethyl 5-fluorohexoate, $F(CH_2)_5COOC_2H_5$, a stable colourless liquid. We found that the toxicity of this compound was very high, and by injection into mice had an L.D. 50 of about 4 mgm./kgm. Ethyl 5-fluorohexoate was therefore about three times as toxic as methyl fluoroacetate (per molecule).

We showed in April 1943 that 2-fluoroethyl fluoroacetate was about twice as toxic as methyl fluoroacetate by inhalation[7]. It seemed likely then that the 2-fluoroethyl ester of 5-fluorohexoic acid might be a compound of outstanding toxicity, and this proved to be the case[6]. This compound was made by the method as outlined below:

$$Br(CH_2)_5COOH \xrightarrow[H_2SO_4]{FCH_2CH_2OH} Br(CH_2)_5COOCH_2CH_2F$$

$$\xrightarrow{AgF} F(CH_2)_5COOCH_2CH_2F.$$

The L.D. 50 of 2-fluoroethyl 5-fluorohexoate, as determined by subcutaneous injection into mice was 2·5 mgm./kgm., that is to say that it is about eight times as toxic as methyl fluoroacetate (per molecule).

For purposes of comparison, the toxicity of methyl fluoroacetate, 2-fluoroethyl fluoroacetate, ethyl 5-fluorohexoate and 2-fluoroethyl 5-fluorohexoate are shown in the accompanying table. The inhalation figures are for 10 minutes exposure. The toxicity of 2-fluoroethyl 5-fluorohexoate, though high by inhalation, was not quite so pronounced as might have been expected; but this is probably accounted for by the fairly low volatility of the compound. For purposes of comparing the toxicities of compounds of low volatility, it is probable that injection experiments are more reliable than inhalation experiments.

Compound	Mice L.D. 50 sub.-cut. inject. (mgm./kgm.)	Mice L.C. 50 Inhal. (mgm./l.)	Rabbits L.D. 50 intra-venous inject. (mgm./kgm.)	Rabbits L.C. 50 inhal. (mgm./l.)	Rats L.D. 50 intra-mus. inject. (mgm./kgm.)	Rats L.C. 50 inhal. (mgm./l.)
Methyl fluoroacetate	7–10	3·2	0·25	0·025–0·05	2·5	0·3
Ethyl 5-fluorohexoate	4	0·2	0·2–0·5		2·3	
2-fluoroethyl fluoroacetate	8·5	0·45		0·05		0·15
2-fluoroethyl 5-fluorohexoate	2·5	0·15	0·1–0·2	0·02–0·05	1·8	0·2

The very high toxicity of 5-fluorohexoic acid and its derivatives is interesting, since by a process of beta-oxidation it could readily give rise to fluoroacetic acid in the body. Similar remarks apply to 3-fluorobutyric acid prepared by American workers. On the other hand, 2-fluoropropionic acid could not, presumably, be oxidized by the beta-oxidation process to fluoroacetic acid.

In order to ascertain more completely whether this striking alternation in toxic properties was fortuitous, we then prepared other ω-fluoro-carboxylic esters, none of which had previously been described[8]. Ethyl-4-fluorovalerate, $F(CH_2)_4COOC_2H_5$, was shown to be non-toxic. On the other hand, we showed that ethyl 9-fluorodecoate, $F(CH_2)_9COOC_2H_5$, was extremely toxic in accordance with expectation, but the toxicity figures were considerably greater than would have been anticipated on the β-oxidation theory. In fact, molecule for molecule, it was much more toxic than methyl fluoroacetate. It may be argued that because of its longer chain, the fluorodecoate would have a higher 'fat : water' distribution, and would therefore pass more rapidly than methyl fluoroacetate through the cell membrane, and there break down giving a higher intracellular

Compound	LD. 50 for injection into rabbits
FCH_2COOCH_3	0·25 mgm./kgm. (in saline)
$F(CH_2)_9COOC_2H_5$	0·2 mgm./kgm. (in propylene glycol*)

* The fluorodecoate would probably be even more toxic in saline, as methyl fluoroacetate appears to be rather more toxic in saline than in propylene glycol.

concentration. It cannot, therefore, be stated with certainty that β-oxidation is the only factor or even the major factor concerned with the alternation of toxic properties.

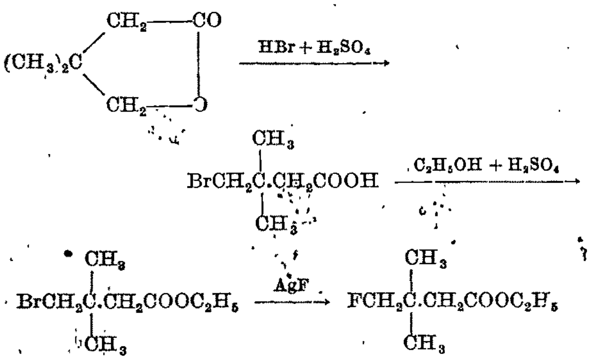
It is also important to keep in mind the fact that 2-fluoroethyl fluoroacetate, $FCH_2COOCH_2CH_2F$, was found to be twice as toxic (by inhalation) as methyl fluoroacetate weight for weight[7]. The rate of hydrolysis of the two substances was found to be similar. One mol. of the former gives rise to one mol. of fluoroacetic acid and one mol. of fluoroethyl alcohol (oxidizable to fluoroacetic acid). Therefore if hydrolysis and oxidation were the major factors concerned, then 2-fluoroethyl fluoroacetate should possess approximately the same toxicity as methyl fluoroacetate (weight for weight). This may indicate that the 2-fluoroethyl fluoroacetate molecule can exert a toxic action *per se*, independent of any subsequent degradation.

In line with this observation, we found that 2-fluoroethyl 5-fluorohexoate was more toxic than the corresponding ethyl ester (by injection). On the other hand, 2-fluoroethyl 9-fluorodecoate does not appear to be more toxic than the corresponding ethyl ester. This result requires further investigation.

We have recently added to the series by the synthesis of ethyl 10-fluoroundecoate, $F(CH_2)_{10}COOC_2H_5$, which was found to be non-toxic, and of ethyl 7-fluorooctoate and 11-fluoroduodecoate, both of which proved to be highly toxic.

Acids Substituted in the β, and in the α and β, Positions

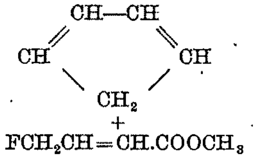
The problem was then approached at a different angle. As already stated, 3-fluorobutyric acid is known to be highly toxic, a fact which could be accounted for on the β-oxidation theory. The process of β-oxidation could presumably be stopped by effectively 'blocking' the β-position in the chain. We therefore synthesized ethyl 2 : 2-dimethyl 3-fluorobutyrate (I) according to the following scheme :



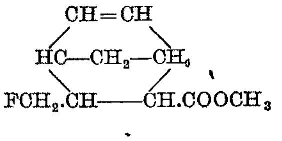
(I)

The compound (I) was found to be non-toxic as expected.

An independent method of approach consisted in 'fixing' carbon atoms 2 and 3 in the highly toxic 3-fluorobutyrate by making them form part of a ring system. Presumably the process of β-oxidation would be inhibited in the new compounds, which should therefore be non-toxic. For this purpose we carried out a Diels–Alder condensation of cyclopentadiene and methyl 3-fluorocrotonate (II), and obtained the compound (III), which was, in accordance with expectation, non-toxic.



(II)



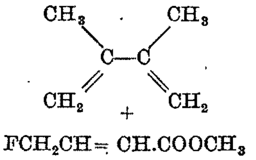
(III)

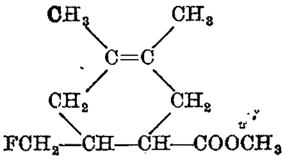
It should be mentioned here that the crotonate (II) had been shown by American workers to be highly toxic. For the present investigation we prepared the compound as follows :

$$\mathrm{CH_2{=}CH.CH_2OH \xrightarrow{Cu_2(CN)_2+HCl} CH_2{=}CH.CH_2CN \xrightarrow{Aq.HCl} CH_2{=}CH\,CH_2COOH \xrightarrow{HCl,\,CH_3OH} CH_2{=}CH.CH_2COOCH_3 \xrightarrow{Br_2} BrCH_2CHBr.CH_2COOCH_3 \xrightarrow{NaOEt} BrCH_2CH{=}CH.COOCH_3 \xrightarrow{AgF} FCH_2CH{=}CH.COOCH_3.}$$

The methyl bromocrotonate was also prepared by the action of N-bromosuccinimide on methyl crotonate.

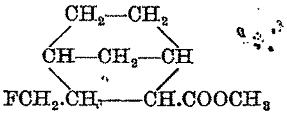
We also effected the condensation between 2 : 3-dimethylbutadiene and methyl 3-fluorocrotonate and obtained the hitherto undescribed compound (IV), which was devoid of toxic properties.



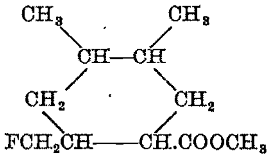


(IV)

It was found that compounds (III) and (IV) could be hydrogenated under conditions which did not remove the fluorine atoms, and the fully saturated compounds (V) and (VI) were also found to be non-toxic.



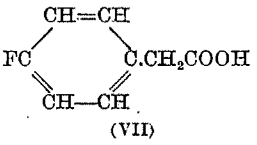
(V)



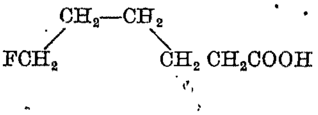
(VI)

Thus five compounds in all were synthesized, containing the skeleton of the toxic 3-fluorobutyric ester. They possessed structures of such a kind that β-oxidation would be unlikely in the animal body. The fact that these new compounds were non-toxic is some evidence in support of the β-oxidation theory. On the other hand, if their toxic properties had been comparable with that of the parent acid, it would have been necessary to have abandoned the β-oxidation theory.

One further compound may be mentioned in this connexion, namely, *p*-fluorophenylacetic acid (VII), which has the carbon skeleton of the highly toxic 5-fluorohexoate (VIII) :

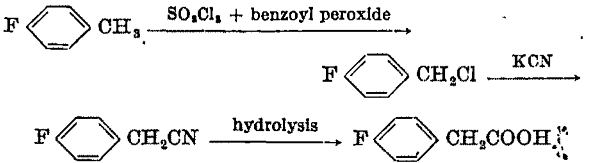


(VII)



(VIII)

The compound (VII) was found to be non-toxic, and cannot, of course, be oxidized to fluoroacetic acid. *p*-Fluorophenylacetic acid had previously been prepared in small quantity by Dippy and Williams[9] by a rather laborious process. We developed a new synthesis of the compound (VII) in good yield as follows :



(VII)

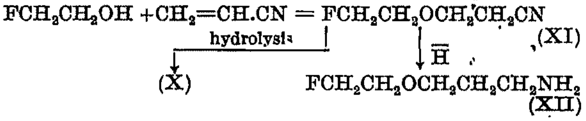
ω-Fluorocarboxylic Acids Containing a Hetero-Oxygen Atom.

We have also devised another method[8] which may throw light on the phenomenon of alternating toxicities and the possible connexion with the β-oxidation process. Here the principle was to replace a CH_2-group at some appropriate point in the chain by an oxygen atom, and then to compare the toxic action of the new compound with that of the parent ω-fluorocarboxylic acid. Thus whereas 5-fluorohexoic acid (IX) and its derivatives are extremely toxic, the corresponding oxygen compound (X) had an L.D. 50 for injection into mice of only 70 mgm./kgm.

$FCH_2CH_2CH_2CH_2CH_2COOH$ (IX) L.D. 50 : 4 mgm./kgm. for ethyl ester.

$FCH_2CH_2OCH_2CH_2COOH$ (X) L.D. 50 : approx. 70 mgm./kgm.

Several compounds of this type have been prepared by a novel synthesis depending upon the cyano-ethylation of the appropriate fluoro-alcohol. Thus the cyano-ethylation of fluoroethyl alcohol (prepared according to the method of McCombie and Saunders[10]) gave 2-fluoro-2′-cyanodiethyl ether (XI) in good yield.



$$FCH_2CH_2OH + CH_2{=}CH.CN = FCH_2CH_2OCH_2CH_2CN \quad (XI)$$

$$\xrightarrow{\text{hydrolysis}} (X) \qquad \xrightarrow{\bar{H}} FCH_2CH_2OCH_2CH_2CH_2NH_2 \quad (XII)$$

It was found possible to reduce the ether (XI) to the corresponding primary amine (XII) by means of Raney nickel and hydrogen, without removing the fluorine atom. The conditions for the reduction were critical and were arrived at only after several failures. This then allowed of the possibility of lengthening the chain at one end of the molecule. Increase in length at the other end of the molecule was achieved by the cyano-ethylation of 3-fluoropropanol.

Utilizing the cyano-ethylation method, the following compounds, all of which are new, have been prepared :

$FCH_2CH_2CH_2OCH_2CH_2CN$
$FCH_2CH_2CH_2OCH_2CH_2COOH$
$FCH_2CH_2CH_2OCH_2CH_2COCl$
$FCH_2CH_2CH_2OCH_2CH_2CH_2COOC_2H_5$
$FCH_2CH_2OCH_2CH_2COCl$
$FCH_2CH_2OCH_2CH_2CH_2COOC_2H_5$

The acid chlorides were converted into the esters of the higher acids by the Arndt–Eistert reaction :

$$F(CH_2)_3OCH_2CH_2COCl \xrightarrow{CH_2N_2} F(CH_2)_3OCH_2CH_2COCHN_2 \xrightarrow{Ag_2O + C_2H_5OH} F(CH_2)_3O(CH_2)_3COOC_2H_5 + N_2.$$

The physiological examination of these ethers is being undertaken at present.

Summary

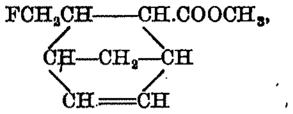
(1) A striking alternation in the toxic properties of ω-fluorocarboxylic esters has been demonstrated as follows :

FCH_2COOR	toxic
FCH_2CH_2COOR	non-toxic (American workers)
$F(CH_2)_3COOR$	toxic (American workers)
$F(CH_2)_4COOR$	non-toxic
$F(CH_2)_5COOR$	toxic
$F(CH_2)_7COOR$	toxic
$F(CH_2)_9COOR$	toxic
$F(CH_2)_{10}COOR$	non-toxic.
$F(CH_2)_{11}COOR$	toxic

These results are discussed from the point of view of β-oxidation in the animal body. The conclusion is that while β-oxidation may be a factor in accounting for this alternation of properties, other important factors are also involved.

(2) Ethyl 2 : 2-dimethyl 3-fluorobutyrate, $FCH_2C(CH_3)_2CH_2COOC_2H_5$, in which the β-position is 'blocked', is found to be non-toxic.

(3) Methyl 2-fluoromethyl-3 : 6-endomethylene-Δ^4-tetrahydrobenzoate,



and three other related compounds in which the α and β positions are 'fixed', are non-toxic.

(4) We have been able to introduce a hetero-oxygen atom at appropriate points in the chain of ω-fluorocarboxylic acids by methods depending ultimately upon the cyano-ethylation of the appropriate fluoro-alcohol. Thus compounds of the general type $F(CH_2)_mO(CH_2)_nCOOH$ have been obtained. The toxic properties of these compounds are at present being examined.

These investigations were carried out by F. J. Buckle, F. L. M. Pattison and B. C. Saunders. We express our thanks to Imperial Chemical Industries, Ltd., for research studentships to two of us (F. J. B. and F. L. M. P.). We are indebted to Mr. K. J. Carpenter and to Dr. W. J. O'Connor, who have performed the animal experiments.

DUNDEE MEETING OF THE BRITISH ASSOCIATION, AUGUST 27–SEPTEMBER 3

AS has already been announced, the British Association will meet at Dundee during August 27–September 3, and a preliminary programme referring to general features of the meeting has been issued. The following notes, from the recorders of the various sections, amplify the information given there.

Section A (*Mathematics and Physics*). In his presidential address, Sir Edward Appleton will deal with the way in which radio has been used in communication and also as a method for investigating natural phenomena, by study of the reflexions from meteors and the reception of radio 'noise' from the sun and Milky Way. The session on September 2, devoted to "Coal as a Source of Heat and Power", will hear Sir Charles Ellis, who will be followed by contributors from the Fuel and the Building Research Stations on the efficient use of fuel and domestic heating systems. Prof. J. D. Bernal will review the question of coal economy, and Prof. D. M. Newitt will speak about the use of oxygen in carbonization processes and the storage of gases in liquid form. The British Coal Utilisation Research Association will deal with the combustion of coal in fuel beds. The discussion of modern methods of computation will include a general survey and a description of some large American machines.

Section E (*Geography*) will devote a whole day to a discussion of Scottish problems from the geographer's point of view. The National Atlas and urban geography will each have a morning. There will be an exhibition of maps produced by the Scottish Department of Health and the Ministry of Town and Country Planning.

Section F (*Economics*). Current economic difficulties will receive particular attention. The presidential address is to be on the "Conditions of the Economic Outlook", and there will be papers on "The Significance of the New Issue Market for the Finance of Industry", "Land Compensation", "Social Accounting", "Profit and Enterprise", "Proposed Code of Industrial Management". A joint meeting with Section J (Psychology) will consider "Incentives in Industry".

Section G (*Engineering*). An outstanding feature will be a series of short papers by junior engineers; thirty minutes is allotted to each speaker for his paper and the ensuing discussion. In preparation for the afternoon visits, the last item of the morning programme will be a summary of what is to be seen.

Section H (*Anthropology*) will hold a symposium on problems of "Culture Change", to which members of the staff of the London School of Economics will contribute. The archæological side will discuss Pleistocene chronology under the title "Dating the Past". Papers are to be presented on a variety of subjects, including the technique of excavation, the education of the totally deaf child, the organisation of folk-life studies, reconstruction in the Naga Hills, and recent discoveries of fossil Hominoidea in South Africa.

Section I (*Physiology*) will hold a joint meeting with Sections H and J to discuss "Man and the Machine", with the object of showing how the physiology, anatomy and psychology of the man should be considered in the design of the machine he is to use. Two other meetings include Section J, when "Aviation Physiology" and "Climate and Health" will be discussed. On August 29 Sir Alexander Fleming will open a symposium with Sections B and K on "Penicillin and other Antibiotics". The use of tracer elements will be the subject of a meeting with Section B on the morning of September 2. During the meeting a Children's Lecture on "Colour" will be given by Prof. H. H. Hartridge.

Section J (*Psychology*). The contributions are mainly of practical interest, industrial and educational applications being especially prominent. The Section joins with others in discussing "Man and the Machine", "Allocation to Secondary Education" and "Incentives in Industry". The sectional meetings include symposia on "Selection for Management", "Public Opinion Surveys", "Rehabilitation of an Industrially Depressed Area", "Changes in Abilities with Age" and "The Scientific Study of National Character". Dr. S. J. F. Philpott's presidential address is "Man's Adaptability".

Section L (*Education*). Miss Grier's presidential address will be on the evolution of secondary education. Miss Lambert will present a paper on the "Problems of Selection Technique at the age of Transfer to Secondary Schools". There will be a discussion on adult education in the Services.

Section M (*Agriculture*). The first session will be a joint one with Sections B and D to discuss insecticides. Papers will be presented (by Drs. H. G. Thornton, M. C. Rayner and A. P. Evans) on three aspects of soil biology—the roles of bacteria, mycorrhizas and earthworms in the economy of the soils and the maintenance of fertility. A session is devoted to recent advances in the control of animal diseases, and at the final session the Right Hon. Walter Elliott, M.P., Sir Jack Drummond and Mr. H. D. Walston will discuss, from the points of view of the agriculturist, nutritionist and economist, respectively, the vitally topical problem: How far could and should Britain feed herself? In his presidential address, Dr. W. G. Ogg will speak on "Soil and Health", and will describe recent studies on the effect of soil conditions on the health of plants and animals.

METALLURGICAL PROBLEMS INVOLVED IN THE GENERATION OF USEFUL POWER FROM ATOMIC ENERGY*

THE design of even the simplest atomic energy reactor, the water-cooled carbon pile using natural uranium, presents many awkward technical problems. Metallic uranium has properties which make it a difficult material to work with. It melts at about 1,150° C.; but below this temperature it undergoes two transitions, with unusually large volume changes. It is very reactive chemically, and readily attacked by water. For these reasons, and to retain the radioactive fission products, the uranium rods in a pile have to be enclosed in gas-tight sheaths, of materials which are good heat conductors, non-corrosive and do not absorb neutrons appreciably.

* Substance of the May Lecture before the Institute of Metals delivered by Sir Wallace Akers, C.B.E., on May 21.

These conditions limit the choice to beryllium and aluminium. Beryllium would be excellent, but so far nobody has succeeded in making tubes from it. Aluminium has therefore to be used, although it is not ideal, as water tends to form surface films, which interfere with the heat transfer. The uranium and graphite have to be purified to a degree hitherto unknown on such a scale; the most important impurity is boron, which seems to be present in very small quantities in almost all reagents. The preparation of aluminium-sheathed rods of uranium of the required purity represents a metallurgical achievement of a very high order.

But even when these difficulties have been overcome, it is unlikely that water-cooled plants will produce useful power. In order to achieve a reasonable thermal efficiency, the water would have to be worked at a considerable pressure; the aluminium tubes would therefore have to be much thicker and would consequently capture too many neutrons. More promising is the use of liquid bismuth, or helium, both of which have very low neutron-capture cross-sections. Even then the pile would have to be very large and its design extremely critical; because the very narrow balance between the number of neutrons produced at fission and those left after capture by U238 and the various materials entering into the construction of the pile necessitates the cutting down of the escape of neutrons and their loss in impurities to a minimum.

Much smaller reactors and greater latitude in design become possible, if, instead of ordinary uranium, material enriched in fissile content is employed. The use of uranium enriched in U235 is not economical because of the high cost of separation; but it is feasible to utilize the production of plutonium by capture of neutrons in U238. This may be of vital importance for the supply of fissile fuel, because if it could be arranged that, for every nucleus of U235 burnt up, one plutonium nucleus were produced, the total number of fissile nuclei would remain constant; in fact, their proportion would increase steadily as U238 is being used up. One cannot say at present whether it would be possible to go further than this and produce more plutonium nuclei than of U235 burnt up. If such 'breeding' of plutonium could be achieved, the problem of availability of supplies of fissile fuel would be solved immediately.

In this respect the production of U233 from thorium is more promising. This is done by placing thorium in the outer layers of a graphite-uranium pile so that it is exposed to neutrons which would otherwise escape. The possibility of 'breeding' is in this case more pronounced, since the number of neutrons ejected at fission of U233 may be sufficiently high to make it possible to build a reactor in which more nuclei of U233 are formed than are burnt up. If this turns out to be practicable, then, having once made some U233 from thorium placed in a uranium pile, we could dispense with natural uranium altogether and continue to produce U233, and generate power, using only thorium as a raw material. Furthermore, this would enable us to utilize, by conversion to plutonium, any U238, from graphite-uranium piles, which became useless owing to the impoverishment in U235.

When will atomic energy be available? As a pure guess it would seem that an experimental plant will be running in the United States by 1949, and that in five to ten years there will be some fairly large power stations generating electricity in various parts of the world. It is impossible to say anything definite about the economics of these plants. The figures quoted recently in the United States depend on several assumptions and data not available in Britain; but for more remote places, without fuel resources, atomic power may well be economical even now. For example, an atomic energy power station might be built to provide power and heat for a large airport near the North Pole, to shorten many important air routes.

The consumption of nuclear fuel is extremely low; one kilogram of fissile material liberates as much heat as the burning of 2½ million kilograms of high-grade bituminous coal. The amount of electrical energy generated in Great Britain is about 50,000 million kWh. per annum. If the heat generated in fission could be utilized with a thermal efficiency of 27 per cent, the consumption of fissile material needed to produce this amount of electrical energy would be about 7½ tons per annum. If only U235 were burnt, the quantity of ordinary uranium required would be about 1,000 tons per annum, which is just what the total world output of uranium was in 1939. Although the production has since then certainly increased, it is clear that uranium has no future for power production if only U235 could be utilized. But if a substantial part of U238 or, still better, if thorium could also be used, then the figures become reasonable.

Contrary to common belief, uranium and thorium are far from being among the rarest elements. In the rocks composing the globe there are on the average about 4 parts per million of uranium and 11½ of thorium, as compared with 0·5 of mercury and only 0·005 of gold. But unfortunately uranium does not occur frequently in large enough concentrations; thorium is rather better in this respect. Granites and rhyolites contain 10 to 20 grams of uranium plus thorium per ton; their 'calorific' equivalent is thus 25 tons of coal per ton of rock; but the very complex nature of the compounds in which uranium and thorium exist in them makes it impracticable to mine and extract the fuel from rocks.

AN INTERNATIONAL UNION OF FAMILY ORGANISATIONS

A MARKED tendency in educational and social thought of recent years, and a tendency accentuated by the strains to which society has been subjected by the War and the ensuing peace, has been the renewed emphasis placed on the family as the basic social unit and as the most powerful educational influence acting upon the individual. It is therefore not surprising that in various countries efforts have been made to set up organisations to co-ordinate activities relating to family life; organisations such as the National Council on Family Relations in the United States, the Family Relations Group in Great Britain, and the Union Nationale des Associations Familiales in France. The next needed step was clearly the formation of some machinery for international information and documentation, and the building of this machinery has now been started.

In Paris, during June 22–29, there was held an International Congress on the Family and on Population. It was attended by some two hundred delegates from twenty-four countries and, although few of the delegates attended with the official support of their

Governments, there seems little doubt that the Congress was fairly representative of the main streams of thought in most of the important countries of the world.

This very fact, indeed, was responsible for what at first appeared to the writer to be a weakness in the Congress. When some delegates were enthusiastic about large families and others little concerned with mere family size, when some were interested in the problems and techniques of family planning and others condemned it as immoral, when some represented still quite patriarchal countries and others countries in which women were fully recognized as the equals of men, it was difficult to get down to any detailed discussion or expert examination. In truth, it could not be claimed that this Congress achieved anything very important in the way of settling the problems of family life. It did, however, provide an opportunity for the exchange of information and widely differing views on housing and home-making; sex education, marriage guidance; and general education for family life; the role of women in general (and mothers in particular) in society; family allowances and other social measures for the strengthening of family life; the role of family organisations in national life, and so on.

Out of this exchange there emerged, despite all differences of opinion, a widespread and deep desire for international co-operation. Most delegates felt that they could learn much, and perhaps most of all from those from whom they differed most widely. Towards the end of the Congress, this diffuse desire for international co-operation gradually crystallized into a determination to set up an international organisation and, at the final session, a resolution to this effect was passed unanimously.

The new organisation is to be called the International Union of Family Organisations; but it was clearly recognized that all decisions as to structure and programme could at present be purely provisional. The British delegates, in common with those from most other countries, felt that they had no mandate whatsoever to commit their countries or even the organisations they represented to anything very concrete. Equally, however, they felt that it would be a great pity to allow this very representative gathering to disperse without forming at least an embryonic organisation. A provisional international committee was therefore set up, a Swiss delegate was appointed as provisional president, and a French delegate as provisional secretary. It was agreed that vice-presidents should, if possible, eventually be appointed from the United States, Great Britain, France, 'Eastern Europe' (by which the U.S.S.R. was generally understood to be meant), Scandinavia, South America, the Near East and the Far East; and, no doubt, it was by an oversight (for these provisional arrangements were necessarily made hurriedly) that Africa and Australasia were not included in this list. Finally, it was agreed that the International Union should be open to all countries, including those not represented at the Congress, and that every effort should be made to work closely with U.N.O. and U.N.E.S.C.O. It is encouraging to be able to report that an observer from U.N.O. welcomed the establishment of the International Union.

Whether the future will see a great strengthening of the new International Union of Family Organisations, or whether it will see its gradual withering, it is as yet impossible to say. Everything depends upon whether the action of the delegates is ratified when they report back to their respective national organisations. One most encouraging fact, however, is that throughout the world to-day there is great interest in the problems of family life. Catholics and Protestants, Capitalists and Communists, all, in their different ways, recognize the importance of the family, and in this lies great hope.

CYRIL BIBBY

NEWS and VIEWS

East African Agricultural and Forestry Research: Dr. B. A. Keen, F.R.S.

DR. B. A. KEEN has been appointed director of the new East African Agricultural and Forestry Research Organisation. The Organisation will work in close association with the corresponding Veterinary Organisation and the Agricultural Departments of Kenya, Uganda, Tanganyika and Zanzibar. For many years Dr. Keen was assistant director and head of the Physics Department at Rothamsted Experimental Station. During 1929–31, at the request of the Government of India, he was seconded as director of the Imperial Agricultural Research Institute to reorganise it. During 1943–45, he was scientific adviser to the Middle East Supply Centre. In 1946 he revisited Palestine to advise on the organisation needed for rural development and also went to West Africa as chairman of the United Kingdom Government Mission to inquire into the production of vegetable oils and oil seeds. Since February 1947 he has been touring East Africa at the invitation of the Governors' Conference to examine agricultural problems and research needs.

Recordings at Kew of the Brest Explosion

MR. J. M. STAGG, of the Kew Observatory, Richmond, Surrey, writes that the effects of the explosion of a cargo of nitrate in Brest harbour on the evening of July 28 were clearly recorded on one of the seismographs and on four barographs at the Observatory, which is 480 km. from Brest. The seismograph, a short-period, vertical component instrument, recorded the first effect at 16h. 48m. 52s. G.M.T. with a second pulse nine seconds later. The biggest amplitude occurred at 16h. 49m. 05s. and the whole disturbance lasted about one minute. The character of the effect on the seismograph closely resembled the effects produced by bomb explosions, flying bombs, etc., in the neighbourhood of the Observatory during the War, when, for the most part, the disturbances were due to airborne sound waves. That the seismograph disturbance was due to the explosion air wave and not to true earth movements is supported by the times of the disturbance recorded by the Kew barographs, including a very sensitive microbarograph. All four instruments showed a sudden pulse (about one millibar) of very short duration in both directions, the mean of the times being 16h. 49m. 0s. ± 15s. The Kew records taken together put the time of the Brest explosion at about 16h. 25m. G.M.T.: there was no indication of an earth movement or an upper air sound wave.

Audibility of Members of Parliament

EXPERIMENTS are being conducted in the House of Lords, in which the House of Commons sits while the Lower Chamber is being rebuilt after destruction during the War, to improve the audibility of members. Comprehension of a speaker's words is low because the first major reflextion, on which reliance is placed by auditors, especially in the rear of a speaker, is scattered by the extensive wooden carving; moreover, the roof is too high to afford any useful reflexions. The acoustic problem is complicated by the premise that any speaker may jump up and address remarks, theoretically to the chair, but often elsewhere. Permission from the authorities has been obtained to install, as an experiment, three hollow tubes acting as hand-rails, one on each side of the House behind the Treasury and Opposition benches, the third in front of the Hansard and some Press reporters just over the Speaker's chair. Each tube is driven by a horn loudspeaker electro-dynamic driving-unit at one end, the other end having an acoustic termination to obviate reflexions. Along the pipe are small holes, so that reproduced sound from the existing system of microphones is emitted just below a member's ear, or in front of a reporter. It is unlikely that a considerable increase in general audibility can be obtained by any means; but the pipe scheme for low-level individual sound augmentation certainly helps the audition of poor speakers, and is of considerable help when the noise-level increases. In particular, the Press are much more certain of getting the remarks of the Speaker. Present trials will indicate whether the pipe system can be extended with advantage, and possibly incorporated in the new Lower Chamber.

Advisers to the Minister of Civil Aviation

LORD NATHAN, the Minister of Civil Aviation, has appointed the following to be his advisers in science, business and industrial relations: chief scientific adviser, Prof. George Temple; chief business adviser, Mr. Leslie Gamage; chief adviser on industrial relations, Lord Dukeston. Prof. Temple is professor of mathematics in King's College, London. He is also a member of the Aeronautical Research Council. He was seconded for specialist duties to the Royal Aircraft Establishment, Farnborough, during the Second World War. Mr. Leslie Gamage is vice-chairman and joint managing director of the General Electric Co., Ltd. For the past four years he has been president of the Institute of Export. He is a member of the National Civil Aviation Consultative Council, representing the Joint Air Transport Committee of the Association of British Chambers of Commerce, the Federation of British Industries and the London Chamber of Commerce. Lord Dukeston was the general secretary of the National Union of General and Municipal Workers. He represents the Trade Union Congress on the National Civil Aviation Consultative Council. He was president of this year's Trade Union Congress, and is the British Government member on the United Nations Organisation Commission to set up a Bill of Human Rights.

Royal Society Empire Scientific Conference

THE preliminary report of the Royal Society Empire Scientific Conference, June–July 1946, which has now been published by the Royal Society, includes the speeches at the opening ceremony with lists of the morning discussions, of the papers prepared for the Conference, of the delegates, etc. The summaries of the discussions given in this report detail the recommendations (see *Nature*, July 27, 1946, p. 136), many of which were afterwards endorsed by the Official Conference. The morning discussions surveyed first some outstanding problems in agricultural science in the Empire, including scientific needs concerned with the soil, the plant and the farm animal. Next some outstanding problems in medical science were discussed, including the physiological and psychological factors affecting human life under tropical conditions and in industry, and the etiology and control of infectious and transmissible diseases, particularly those which are insect-borne. The present state of the science of nutrition was discussed with particular reference to the special problems of the Empire, including the nutritional status of the indigenous peoples of the Colonies. Improvement of that status was recognized by the Conference as a part of general social and economic policy in the territories concerned, and the Conference strongly urged the need for integrating the efforts of producer, consumer, technical and administrative personnel in effecting improvements in nutrition.

Other discussions covered a variety of topics: modern methods of mapping and exploration by air, including the use of radio technique in ordnance survey with special reference to particular parts of the Empire; scientific information services and methods of improving the interchange of scientific workers throughout the Empire, including the future of the scientific liaison offices that were established during the War; Empire co-operation in the scientific field with existing and projected international organisations; physical standards of measurement, the collection of scientific records and material and risks involved in the distribution of plants, seeds and animals, and so on. A general statement on land utilization and soil conservation emphasizes the importance of erosion surveys, soil surveys, and investigations relating to the maintenance and improvement of soil fertility, and urges the importance of surveys to determine the present pattern of and trends in land use, as a basis for the maintenance of soil fertility, bearing in mind the conflict between agricultural and other interests. A discussion on the need for a co-ordinated survey of the mineral resources of the Empire led to a general statement urging the compilation of reliable data on mineral resources. Discussions on the natural products of the Empire and the chemical industries that are, or might be, based on them and on the post-war needs of fundamental research, the latter of which revealed a particular shortage in the Commonwealth of scientific workers in such fields as taxonomy, genetics and microbiology, completed the proceedings.

Textile Industry and the University of Leeds

THE report to the Clothworkers' Company of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing, University of Leeds, 1945–46, pays a high tribute to the work of the late Prof. F. M. Rowe. No appointment has yet been made to the research fellowships in dyeing or in physical chemistry; but research workers of the Sisal Growers' Association have continued to be accommodated in the Dyeing Department. Dr. E. Race, in collaboration with Prof. Rowe and Prof. J. B. Speakman, established a new technique for examining the constitution of the dye-chromium complexes obtained when wool is dyed with chrome mordant dyes, and with Dr. C. B. Stevens commenced work on the kinetics of chromium dye complex formation, including a study of the rates of formation and heats of combustion of chromium complexes of a series of dyes. Dr. E. M. Hunt and Prof. F. M. Rowe completed an investigation to establish degradation processes for determining the constitution of indigoid, thioindigoid and related types of vat dyes in substance, and Mr. F. M. Smith commenced a similar investigation of triphenylmethane dyes. Derivatives of catechol have been prepared for examination as intermediates for dyes, and Dr. A. T. Peters has completed an investigation of derivatives of 3 : 4-di-*tert.*-butylacenaphthene and derived indigoid dyes, and with Dr. R. J. Moualim commenced the preparation and orientation of a series of derivatives of 2-*tert.*-butylnaphthalene. Although the entry of British students was seriously affected by the demands of national service, the total number was fully maintained by ex-Service students and students from abroad, and the number of students in the Department of Textile Industries caused serious overcrowding.

The report of the latter Department refers to Prof. W. T. Astbury's election to the newly instituted chair of biomolecular structure, and when his work is transferred to new quarters, the Textile Physics Laboratories will be supervised by Mr. H. J. Woods, who has now been appointed lecturer in textile physics. A new scheme of work on textile finishing has been undertaken by Dr. C. S. Whewell in conjunction with Mr. C. R. Ricketts, and work on wool, rayon, jute and sisal has continued. Messrs. Courtaulds, Ltd., have now made a grant of £60,000 for building and equipping a Division of Rayon Technology within the Department. Lists of publications are included in the report.

Mosquitoes and Yellow Fever in the Sudan

Dr. J. Lewis, of the Stack Medical Research Laboratories, has discussed the relationship of mosquitoes and yellow fever in the Sudan (*Bull. Ent. Res.*, **3**, pt. 4; 1947). It appears that most of the southern half of the Sudan is a yellow fever area in the sense that people immune to the disease have been found in many parts of that territory. The chance of the disease spreading to parts hitherto free is liable to be increased by such outbreaks as the great Nuba Mountains epidemic of 1941. It is noteworthy that several towns in the Sudan lie on important air, rail and water routes leading to countries free from yellow fever. Some 140 species of mosquitoes are known from the Sudan, and, of these, twelve kinds are known to be capable of transmitting the yellow fever virus, while several other kinds are suspected in this connexion. Two further species are able to retain this virus throughout life without apparently possessing the ability to transmit the disease by their blood-sucking habits. The object of the present paper is to record information on the occurrence and distribution of mosquitoes in the Sudan. The Anophelines are only briefly considered because they are unlikely to transmit yellow fever. Among the Culicines that affect man and frequent human habitations, *Aedes taylori* is believed to be one of the chief vectors in the case of the Nuba Mountains epidemic. As regards *Aedes ægypti*, it appears that mosquito control measures have had the effect of rendering urban yellow fever epidemics, carried by this species, virtually impossible, and the disease has been exterminated from Khartoum. The relation of *Tæniorhynchus africanus* to the disease is of special interest owing to its wide range and abundance in the Sudan. While there is no evidence that this species can act as a vector, it seems likely that it can act in this way in limited epidemics about the Upper Nile area. The author concludes by discussing the measures of mosquito control in the Sudan, which greatly restrict the possibilities of the spread of yellow fever. At the same time it is evident that the control of a rural epidemic would be difficult to achieve.

University of London Appointments

The following appointments have been announced by the University of London: Mr. E. H. Phelps Brown, University lecturer in economics at Oxford, to the University chair of economics of labour tenable at the London School of Economics as from October 1; Dr. Harold Burton, senior lecturer in organic chemistry at the University of Leeds, to the University chair of chemistry tenable at King's College of Household and Social Science as from October 1; Mr. P. T. Bauer, lecturer in economics at the London School of Economics and Political Science, to the University readership in agricultural economics tenable at the School, as from October 1; Mr. R. H. Coase, lecturer in economics at the London School of Economics and Political Science since 1938, to the University readership in economics tenable at the School as from October 1; Dr. P. C. C. Garnham, senior parasitologist in charge of the Division of Insect-borne Diseases in the East African Medical Service, to the University readership in medical parasitology tenable at the London School of Hygiene and Tropical Medicine; Mr. J. W. H. King, senior lecturer in civil engineering at University College, Nottingham, to the University readership in civil engineering tenable at Queen Mary College as from October 1. Dr. M. M. Loève, lecturer at Birkbeck College, to the University readership in applied mathematics tenable at Birkbeck College as from October 1; Dr. F. T. G. Prunty, lecturer in chemical pathology at St. Thomas's Hospital Medical School, to the University readership in chemical pathology tenable at the School as from October 1; Dr. Richard Rado, lecturer in mathematics in the University of Sheffield, to the University readership in pure mathematics tenable at King's College as from October 1; Dr. F. R. Selbie, assistant pathologist at the Bland-Sutton Institute of Pathology, to the University readership in bacteriology tenable at Middlesex Hospital Medical School as from October 1.

The title of professor of zoology in the University has been conferred on Dr. Alastair Graham, in respect of the post held by him at Birkbeck College; the title of professor of zoology in the University has been conferred on Dr. A. J. Grove, in respect of the post held by him at Queen Mary College; the title of reader in pure mathematics in the University has been conferred on Dr. R. G. Cooke, in respect of the post held by him at Birkbeck College; the title of reader in civil engineering in the University has been conferred on Dr. S. R. Sparkes, in respect of the post held by him at the Imperial College of Science and Technology.

The degree of doctor of science has been conferred on Prof. E. J. King, professor of pathological chemistry at the Postgraduate Medical School.

LETTERS TO THE EDITORS

Elementary Isotopic Analysis: Determination of Nitrogen

WE have recently described an isotopic method for the determination of oxygen[1] and carbon[2] in organic compounds by using heavy oxygen (O^{18}) and carbon (C^{13}) respectively in conjunction with a mass spectrometer. Using the same method, higher precision is possible in the determination of nitrogen and hydrogen, since N^{15} and H^2 (deuterium) are available in higher concentrations (30–35 per cent for N^{15}) than the oxygen isotope (1·2 per cent) and the carbon isotope (10–20 per cent).

In order to extend this method to nitrogen, we have made the following four determinations. Representatives of two types of compounds, heterocyclic and nitro, were chosen in view of the well-known difficulties of analysing them by the standard Kjeldahl method. The compounds used were pyridine ($n^D_{20} = 1{\cdot}5090$) and nitroethane ($n^D_{20} = 1{\cdot}3912$).

A known weight of substance (a) was burned simultaneously with a known weight (b) of pure isotopic $N^{15}H_3$ in a quartz tube, in the presence of an excess of copper oxide, copper and platinum wire, for 45–60 minutes. (Copper and platinum were inserted, of course, to reduce and equilibrate any oxides of nitrogen.) Both the pyridine and the nitroethane were burned at 750° C. The percentage of nitrogen (x) was calculated from our usual formula: $x = 100\,b(m - n)/an$, where m and n are, respectively, the initial and the final percentage excess of N^{15} in the ammonia and nitrogen.

Any air leakage into the sample, either during the run or during analysis, can be corrected for by calculating the air nitrogen contribution from the argon (mass = 40) peak. In a good determination the air nitrogen should be less than 3 per cent of the total nitrogen.

The results obtained are as follows:

	Pyridine, C_5H_5N		Nitroethane, $C_2H_5.NO_2$	
Analysis	1	2	3	4
a, mgm. substance	25·56	30·02	25·04	16·97
b, mgm. N_2, added as NH_3 (using normal at. wt. of N = 14·008)	$1{\cdot}79_5$	4·27	4·43	3·43
m, % excess of N^{15} above normal (= 0·76%) in b	34·84	34·84	32·10	32·10
N^{15} content of equilibrium mixture (%)	10·52 10·59	16·30 16·18	16·50 16·38 16·34	17·55 17·54 17·47 17·43 17·56
Average	10·55±0·04	16·24±0·13	16·41±0·06	17·51±0·05
n, average % excess of N^{15} in equilibrium mixture	9·79	15·48	15·65	16·76
% N in substance, experimental	17·96±0·09	17·79±0·26	18·60±0·14	18·52±0·13
% N, theoretical	17·74	17·74	18·66	18·66

The mean probable deviation from the theoretical value is 0·4 per cent of the nitrogen content; it is within the accuracy and precision of the Consolidated Engineering Corporation's mass spectrograph that we used.

A detailed description of our experiments will be published later.

Difficulties are encountered in the determination of *hydrogen* by this method because of wide differences in the rates of diffusion of protium and deuterium. Additional precise calibrations or changes in the construction of the present mass spectrographs would be necessary before our method can be successfully applied.

We are indebted to Dr. D. Rittenberg of Columbia University for the sample of $N^{15}H_3$ used.

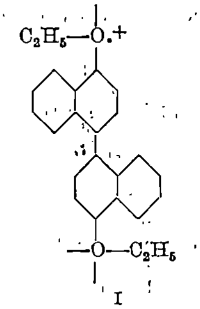
A Semi-Quinonoid Oxidation Product of 4 : 4-Diethoxydinaphthyl

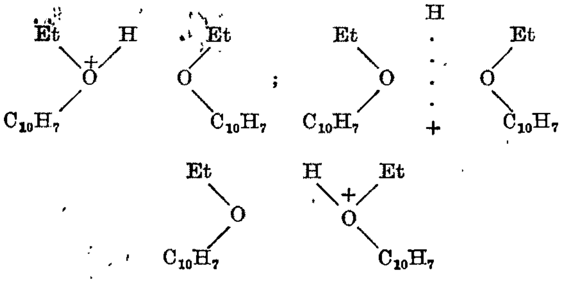
THE communication from Messrs. Hughes, Hush and Mellor[1] reporting a green oxidation product of tetramethyl-benzidine and the projected extension of work to related compounds renders desirable some account of our own work on the green colour instantly developed when 4 : 4′-diethoxydinaphthyl is dissolved in a large excess of concentrated sulphuric acid. The increase of intensity of absorption (measured at 660 mμ) is linear with that of concentration of the dinaphthyl until this reaches c. 310 mgm./litre. The solubility of oxygen in sulphuric acid being 33 mgm./litre[2], calculation shows the green colour to arise from the action of c. 8 gm. oxygen per gm. mol. diethoxydinaphthyl. A similar result follows if selenium dioxide or nitrous acid be used to intensify the colour. We therefore attribute the structure I to the green product.



I

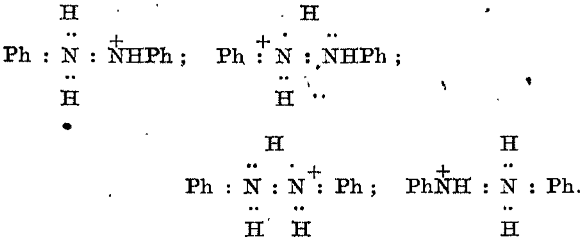
We expect to find that the blue, green and red colours developed by oxidation of diphenol[3], 3 : 3′-dimethyl-4 : 4′-dinaphthol[4], and dianthranol[5] respectively are of the same semi-quinonoid character and will develop in excess of sulphuric acid without further addition of an oxidizing agent.

So far we have been less concerned with isolation of the semiquinonoid product (I) than with the general significance of the facts that: (1) the green colour is destroyed on addition of 1-ethoxynaphthalene, which is itself then converted to 4 : 4′-diethoxydinaphthyl; (2) 1-ethoxynaphthalene itself causes the development of the same green colouring matter in excess of sulphuric acid, but in this case only gradually. Nitric acid, aliphatic and aromatic nitro-compounds, bromine and selenium dioxide all promote the same reaction. Further, aluminium chloride is also effective[6] as a substitute for sulphuric acid, so that the reaction obviously depends on proton activation. This, however, does not involve formation of a naphthylethyloxonium ion, because the ethoxy group survives the oxidation intact, and we must, therefore, be concerned here with an example of protonic disturbance[7], which causes an electronic deficiency on the oxygen atom, in turn made good by a contribution from the oxygen atom of another molecule of 1-ethoxynaphthalene. The resulting complex is responsible for the *red* colour, which is produced when 1-ethoxynaphthalene is dissolved in a small amount of sulphuric acid and fades as the mixture sets to a solid mass of the sulphonic acid. A very similar, if not identical, colour is formed on the addition of aluminium chloride to the ethoxy derivative, and reaches a maximum intensity when the molecular proportions of chloride and ethoxy compound are as 1 : 2. The complex is perhaps best formulated as a resonance hybrid of the three forms :



II

The stages by which this furnishes diethoxydinaphthyl are analogous to those by which the hydrazobenzene-proton complex (which we represent as the hybrid III) yields benzidine[8]. Indeed, Sir Robert Robinson has already adumbrated a connexion between the two types of reaction[8].



III

Parallel with the formation of benzidine there is frequently a decomposition of the hydrazobenzene to azo-derivative and amine. This reaction is specially favoured when the normal benzidine change is hindered or inhibited by 4 : 4′-disubstitution of the hydrazobenzene[9]. It appears not to have been realized that the reaction is exactly comparable with the oxidative splitting of the nitrosomethylaniline-proton complex studied by Jones and Kenner[8]. In more modern form, the correspondence between the two may be exhibited as follows :

$$[\mathrm{PhNHMe}\ \overset{+}{\mathrm{N}}\mathrm{O}] + e \rightarrow \mathrm{PhNHMe} + \mathrm{NO}$$

IV

$$[\mathrm{PhNH_2}\ \overset{+}{\mathrm{N}}\mathrm{HPh}] + \mathrm{PhNH\,.\,NHPh}.$$
$$\rightarrow \mathrm{PhNH_2} + \mathrm{PhNH_2} + \mathrm{Ph\dot{N}} = \mathrm{NPh} + \mathrm{H}^{\cdot}$$

V

Thus, whereas the benzidine change is one in which electronic flow to one or other of the nitrogen atoms is intramolecular, it is intermolecular in the cases just mentioned. A complete description of the relevant proton-complexes in these instances would include, in addition to IV and V, radical forms as in II and III, and such forms were particularized by Jones and Kenner in their paper as operating "within the sphere of each other's action". Any discussion as to whether in this condition, which later was included in the conception of "the transition state", it is homolysis or heterolysis which occurs, is naturally devoid of significance.

Competitive reaction in promoting respectively exchange and substitution processes of proton or other kation, for example, nitronium ions, or nucleophilic reagents, with 1-ethoxy-naphthalene (or, indeed, any benzenoid compound) is, of course, subject to the usual regulative principles. Thus we find nitronium ion in concentrated sulphuric acid solution merely assisting the oxidative process already described as ensuing from proton attack, but very largely, if not exclusively, nitrating in 65 per cent sulphuric acid solution, in which protons are sufficiently diverted to hydroxonium ion formation, and the oxidative process does not occur. The observations of Martinsen[11] on the kinetics of nitration are also to be regarded in this manner rather than as attributable simply to the need for SO_4H' ions as acceptors of displaced protons[12].

Finally, this parallelism between the action of proton and nucleophilic reagents in substitution, coupled with the participation of radical forms in such complexes as II and III, supports the postulation of an analogous transition state, previously described by one of us and invoked to explain the formation of phenol[13] and other products, which frequently accompanies nitration. In fact, it is not too much to say that this general point of view pervades the above co-ordination of a wide range of phenomena.

A fuller account of this work, which will be extended, will be published in due course.

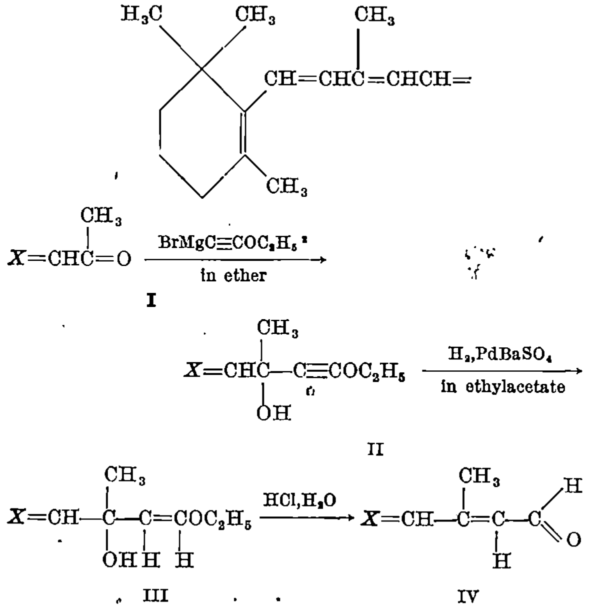
Synthesis of Vitamin A Aldehyde

In our communication in *Nature*, regarding the synthesis of vitamin A acid[1], we stated that "in the course of these investigations we received valuable assistance from Dr. H. H. Inhoffen, who suggested several other approaches to the problems". We have in the meantime learned that Dr. Inhoffen, who is now professor of organic chemistry in Brunswick, feels that the wording of this acknowledgment may give rise to misunderstanding. We therefore wish to point out that in the course of the occupation during the War, Dr. Inhoffen superintended and directed our work on the synthesis of vitamin A acid and vitamin A, and his advice was of great help in our work. When communications between Germany and the Netherlands were broken, joint publication could not be envisaged. We therefore had to single out that part of the work which we thought we could claim in good faith to be based mainly on our own ideas. This we have done to the best of our abilities. After our contact with Dr. Inhoffen ended in September 1944, we pursued the work along new lines and now present further results.

We have prepared vitamin A aldehyde from the C_{18} ketone I[1], as indicated in the following scheme. Writing X for



I

II

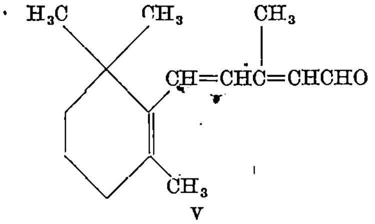
III

IV

The aldehyde was characterized as its crystalline semicarbazone, m.p. 207–209° with decomposition. The absorption spectrum exhibits a well-defined maximum at 3750 A., log $E_{\max} = 4{\cdot}87$. This corresponds with the absorption spectrum of the vitamin A aldehyde oxime[3] obtained by Hunter and Hawkins from natural vitamin A. With antimony trichloride in chloroform a very dilute solution of the semicarbazone in chloroform produces a purple-red colour; with a more concentrated solution the colour is blue-violet.

As the reduction of vitamin A aldehyde, obtained from natural vitamin A, has been previously described[4], a total synthesis of vitamin A now seems to be possible. We intend to synthesize vitamin A_2-aldehyde and vitamin A_3 according to the same scheme, starting from the C_{18}-ketone, derived from pseudo-ionone.

From β-ionone and ethoxyethynylmagnesium bromide we obtain, after an analogous series of reactions to those described above, β-ionylidene acetaldehyde V, identical in all respects with the substance described by Kuhn and Morris[5]. The absorption spectrum of the semicarbazone (m.p. 193–195°) had a single well-defined maximum at 3230 A.



V

With this substance we propose repeating the much discussed synthesis of vitamin A by Kuhn and Morris.

Our thanks are due to the Board of N. V. Organon for permission to publish this paper.

Note added in proof. In the meantime, we reduced the vitamin A aldehyde by means of aluminium-isopropoxide and isopropyl alcohol. After chromatography we obtained an oily fraction containing about 35 per cent of vitamin A according to its absorption spectrum and its biological activity. Further proof was obtained by conversion into anhydro vitamin A.

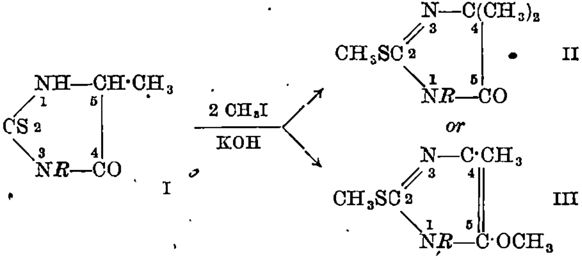
Reported Preparation of Mercaptoimidazole Derivatives by Methylation of 3 : 5-Disubstituted Thiohydantoins

In the examination of the ultra-violet absorption spectra of a number of methylated thiohydantoins, anomalous results were obtained if the structures previously assigned to the methylation products were accepted.



I

II

III

acid $\lambda_{\max.}$ 2330 A.
$\epsilon_{\max.}$ 20,000.
alkali $\lambda\sim$ 2,360-2,420 A.
$\epsilon\sim$ 4,500.
II, R = CH_3.

Thiohydantoins derived from alanine, for example, 2-thio-3 : 5-dimethylhydantoin (I, R=CH_3), methylate readily, two methyl groups being introduced into the molecule. Two products are possible (II and III), and Marckwald, Neumark and Stelzner[1] assigned structure III to the resulting derivative. Examination of the ultra-violet absorption spectra of the compound produced by the introduction of two methyl groups into 2-thio-3 : 5-dimethylhydantoin showed that this was unlikely to be correct. The spectra of this compound under differing conditions of *p*H were, in fact, identical with those shown under the same respective conditions by 1 : 4 : 4′-trimethyl - 2 - mercapto - 5 - ketodihydroimidazole (II, R=CH_3, prepared by the introduction of a single methyl group into 2-thio-3 : 5 : 5′-trimethylhydantoin). If structure III were correct, the conjugated double-bond system should show a spectrum markedly different from that shown by structure II.

Attention was then given to the compounds themselves. The methylated derivatives were bases, oily, and difficult to crystallize, and differing reports are available[2,3] of their properties and physical constants. Methylation products of a number of 2-thio-3-*R*-5-methylhydantoins and 2-thio-3-*R*-5 : 5′-dimethylhydantoins have now been prepared (*R* = methyl, phenyl and *o*-tolyl), and in each case the products of methylation from the two sources were found to be identical. As an example, the sulphate of 1 : 4 : 4′-trimethyl - 2 - mercapto - 5 - ketodihydroimidazole (prepared by monomethylation of 2-thio-3 : 5 : 5′-trimethylhydantoin) melted at 190–191° C.; the sulphate of the base produced by dimethylation of 2-thio-3 : 5-dimethylhydantoin also melted at 190–191° C., and there was no lowering in melting point on mixing the sulphates of the two bases.

It is obvious, therefore, that mercaptoimidazole derivatives (III) are not produced by dimethylation of 2-thio-3-*R*-5-methylhydantoins, the resulting products being 1-*R*-2-methylmercapto-4 : 4′-dimethyl-5-ketodihydroimidazoles (II).

A comprehensive account of this work will be submitted for publication at a later date.

Chemical Constitution of Keratin

WOOL fibres show histological structure when examined microscopically, and this structural heterogeneity has recently been shown in greater detail by the electron microscope[1,2,3]. Apart from some analyses on scale substance by Geiger[4], little chemical evidence on the composition of the different histological components is available. Recently, I have found that wool which has been deamidated by treatment with cetyl sulphonic acid[5] (0·05 *M*, 65°, 6½ days) will partially disperse if stirred in dilute alkali (*p*H *c.* 11, room temperature, overnight), leaving a suspension of the resistant residues of the scales and cortical cells. When the clear alkaline supernatant liquor is acidified to *p*H 4–5, a protein-like material is precipitated which is soluble in either dilute acid or alkali. A fairly complete amino-acid analysis of these components has been carried out and is given in the accompanying table together with data for the intact wool from which they were derived. *A* is the resistant component of the scales and cortical cells, *B* is the portion precipitated from the alkaline liquor, while *Aa* is the resistant residue from retreatment of part of *A* with cetyl sulphonic acid followed by dilute alkali. These analyses show quite clearly a great difference in amino-acid composition between *A* and *B* and the intact wool. The general tendency is for amino-acids of high molecular weight to be concentrated in the soluble component, while the resistant component is particularly rich in cystine and proline. The results thus show great similarities to those of Geiger[4], who probably analysed the resistant component of the scales.

AMINO-ACID COMPOSITION OF WOOL AND COMPONENTS SEPARATED FROM IT. (NITROGEN AS % TOTAL NITROGEN)

	Untreated wool	*A*	*Aa*	*B*
Total nitrogen	16·9	15·4	14·5	13·4*
Total sulphur	3·76	6·16	7·51	4·25*
Cystine	8·0	15·0	20·3	5·2
Phenylalanine	1·9	1·0	0·7	1·7
Leucine	6·7	5·3	3·6	9·2
Valine	3·6	3·9	3·5	4·0
Proline	3·8	6·7	7·6	1·0
Tyrosine	2·6	1·4	1·3	2·0
Alanine	3·2	4·2	3·3	4·0
Arginine	20·0	17·3	15·5	—
Hydroxamino-acids	12·8	14·0	—	—

* Not corrected for bound cetyl sulphonic acid.

Are these different components hydrolytic products of one keratin, or do they represent two keratins? The homogeneous protein insulin has been shown to give a cystine-rich fraction on enzymic digestion[6], and a similar effect has been noted with casein[7]. Moreover, Gordon, Martin and Synge[8] found that proline peptides of gelatin were especially resistant to hydrolysis, although in a later study of the partial hydrolysis products of gramicidin-S the only theoretically possible dipeptide which was not detected was prolyl-valine[9]. Fischer and Abderhalden[10] also found that prolonged enzymic digestion did not liberate free proline from casein, edestin, hæmoglobin, serum globulin, egg albumin or fibrin.

On the other hand, *A* and *Aa* possess recognizable histological structure pointing very strongly to the separation of different keratins pre-existent in the wool fibre. *A* and *Aa* may correspond to the fibrillar component and *B* the matrix substance of wool separated by Rees and Mercer[1,2,3]. Due to the courtesy of Prof. W. T. Astbury, the component *Aa* has been examined under the electron microscope. It is composed of fibrils which Mercer[11] considers to be very similar to the fibrillar component isolated by him. A possible mechanism for the separation of the two components by the present procedure is that deamidation of the matrix component renders it soluble in dilute alkali: a possible analogy for this is provided by the conversion of collagen to gelatin, which is also accompanied by a loss of amide-nitrogen.

If wool consists of more than one kind of keratin, the analytical data of the table throw grave doubt on any theory of wool structure based on correlations between X-ray data and chemical analyses of whole wool. Moreover, the occurrence of such a high percentage of proline residues in the fibrillar component suggests that Astbury's structure for keratin[12] requires modification to include the extensive folding of the chains which these residues cause[13,14]. The high proline and cystine content of the resistant components *A* and *Aa* may have special significance. For example, at least part of the (*C* + *D*) fraction[15] of the combined cystine may owe its inertness to neighbouring proline residues, a suggestion which accords well with the previous hypothesis of the mode of linkage of this portion of the cystine[16].

An attempt to isolate cystine peptides from the $(C + D)$ fraction of the combined cystine of wool is now in progress, and together with full details of the work referred to will be published elsewhere.

Note added in proof. Preliminary qualitative examination of cystine peptides from the $(C + D)$ fraction of whole wool has confirmed the suggestion that proline is associated with this fraction. Glycine, alanine, serine and threonine seem also to be present in substantial amounts.

Application of the Cathode Ray Oscillograph to Measurements of Short Life-Periods of Radioactive Sources

THE most accurate determinations of the life-periods of short-lived radioactive nuclei have been made using either coincidence circuits with variable resolving times[1], or the method of delayed coincidences[2].

Recent developments in cathode ray oscillographs have enabled measurements of this sort to be made in a more direct manner and with standard equipment. In this method, a pulse from one Geiger-Müller counter starts the single sweep on the oscillograph, and the output from a second counter is applied to the vertical plates. If these pulses are due to the radiations from a single radioactive source of short life, then observations on the distribution of the pulses seen on the screen enable an estimate of the half-life of the source to be made.

The method has been applied to the transformation

$$\text{radium C} \xrightarrow{\beta} \text{radium C}' \xrightarrow{\alpha} \text{radium D}.$$

The β-ray from radium C is followed, after a short time-interval, by the emission of an α-ray from the daughter nucleus, radium C′. Observations on these time intervals enable the half-life of radium C′ to be estimated.

A thin-walled vessel containing radon gas was placed between two Geiger-Müller counters. One counter had a window of thickness sufficient to prevent α-particles and most of the β-particles from radium B being recorded. The other counter was operated in the proportional region so that it responded to α-particles only. The stopping power of the window of this counter was such that only radium C′ α-rays could penetrate.

The pulses from the counters were fed through suitable circuits to the oscilloscope, the β-counter initiating the sweep and the α-pulses being applied to the vertical deflexion plates. The instrument used was an Ultrascope, Mark 6, with three speed-ranges, namely, 25, 50 and 500 microsec. Incorporated in the time-base is a calibrating device consisting of an oscillatory circuit 'ringing' at a known frequency. The output of this causes the trace to be intersected by dark gaps representing known time-intervals. Hence visual observation of the pulses enabled their distribution in time to be recorded. Many of the pulses, of course, appear on the screen by chance, and it is necessary to perform control experiments in which the counters are irradiated by separate sources to allow for this.

The corrected distribution in time of the α-pulses shows an exponential fall giving a half-value period for radium C′ of 140 microsec. This result is not so accurate as that claimed for coincidence methods[1,3], but it is thought that the method is capable of being developed for the measurements of much shorter periods, in particular the life-time of metastable states which are of considerable interest theoretically.

Constitution of Alkali Halide-Borate Glasses

Majumdar, Banerjee and Banerjee claim to have demonstrated[1] that sodium chloride dissolved in borax glass was present in the form of crystallites, and also that sodium chloride–boric oxide glasses gave the X-ray diffraction pattern of sodium chloride (together with some unidentified lines). The experimental work and deductions therefrom demand some comment and criticism.

There can be no objection to the experimental results obtained with the halide–borax glasses, since it has been shown that, in such systems as Na_2O—SiO_2 [2], Na_2O—B_2O_3 [3], there is an upper limit to the amount of alkali metal oxide which can exist in the vitreous phase. I have found the same type of phenomenon to occur with the systems CaO—B_2O_3, Na_2O—CaO—B_2O_3, RX—B_2O_3 (where R is Li, Na or K, and X is F, Cl, Br or I) and Na_2O—RX—B_2O_3. Thus a molten mixture of sodium carbonate and silica, in proportions to yield an $Na_2O : SiO_2$ ratio greater than that approximating to the metasilicate, $Na_2O.SiO_2$, separates into two phases on cooling. The crystalline phase, in a vitreous matrix, consists of impure sodium carbonate, probably a double salt of the carbonato-silicate type.

In binary borate systems, the limiting proportions for glass formation approximate to the compositions, for example, $Na_2O.2B_2O_3$ (that is, anhydrous borax), $NaF.2B_2O_3$ and $NaCl.3B_2O_3$. The precipitation of excess alkali compound is particularly well marked in the KF—B_2O_3 system, where a melt containing potassium fluoride, in excess of the limiting theoretical composition $3KF.2B_2O_3$, on cooling can produce very well-developed crystals of the halide up to 3 mm. in size.

The fact, therefore, that melts of borax and sodium chloride yield products which give the X-ray diffraction pattern of the alkali halide is not unexpected.

The glassy matrix itself, however, does not give a well-defined pattern, since it is a true glass, and the alkali halide in this vitreous phase is a part of the random structural arrangement. A complete discussion of the theory of the participation of fluorides and other compounds in the glass network will soon be published elsewhere. I wish, however, to dispute the general statement that alkali halides dissolved in glass are present as crystallites.

With regard to the halide – boric oxide systems, I have found no evidence for the presence of a crystalline phase except when, as stated above, the amount of halide was greater than the particular limiting composition of the system.

Determination of Bilirubin in the Umbilical Blood as an Aid in the Early Diagnosis of Hæmolytic Disease in the Newborn

The bilirubin content of the blood is increased in hæmolytic conditions, as can be demonstrated by the indirect quantitative reaction of Van den Bergh. It seems probable, therefore, that the presence in the umbilical circulation of increased bilirubin, demonstrated by the indirect reaction, might be interpreted as early diagnostic evidence of hæmolytic disease of the newborn.

The bilirubin content of fœtal blood is not dependent on bilirubin of maternal origin, since bilirubin does not pass through the placental barrier[1]. The determination of the normal range of bilirubin in umbilical blood at birth is, however, extremely difficult, since this value varies widely and the fluctuations are associated with a series of factors[2].

In a series of 119 quantitative determinations of bilirubin in the umbilical blood by Van den Bergh's indirect method, we found values varying from traces to 3·6 mgm. per cent. Included in this series were only such cases in which both mother and fœtus were either *Rh*-positive or *Rh*-negative. In 42 of these cases, mother and fœtus had incompatible blood groups, so that immunization of the mother by fœtal erythrocytes was possible (for example, mother in group *A* and fœtus in group *B*, etc.). In this group of cases, 12 (28·5 per cent) had more than 2 mgm. per cent bilirubin in the umbilical blood.

In the remaining 77 cases, the mother and fœtus belonged to the same or to different but compatible blood groups (mother and fœtus both in group *A*, or mother in group *A* and fœtus in group *O*, etc.). In this group bilirubin in the umbilical blood exceeded 2 mgm. per cent in 9 cases (11·6 per cent).

A detailed report on the relationship between the bilirubin value in umbilical blood and the titre of maternal blood antibodies against fœtal erythrocytes will be reported elsewhere.

In 9 additional cases, the mothers were found to be *Rh*-negative, while their fœtuses were *Rh*-positive. In these cases there were from 0·8 to 2·4 mgm. per cent bilirubin in the umbilical blood. Congenital hæmolytic diseases of the newborn did not develop in any of them.

On the other hand, in three cases of *Rh*-negative mothers (two of whom had previously delivered at least one erythroblastotic fœtus) the bilirubin-levels in the umbilical blood were respectively 4·9, 8·1 and 6·2 mgm. per cent. Although the low titre of *Rh* antibodies (agglutinating, blocking and conglutinating) found in the maternal serum in these three cases seemed to indicate that no intensive immunization had taken place, all three newborn infants developed severe hæmolytic disease within 2–36 hours after delivery. Two of them, in whom the bilirubin values in the umbilical blood were 6·2 and 8·1 mgm. per cent respectively, died 38 and 96 hours after delivery. In the first case, the blood count made shortly before death was: erythrocytes 5,160,000 and Hb—17 (Sahli); and at autopsy, kernicterus was found. In the second, the blood count revealed: erythrocytes 1,360,000, Hb—6½ (Sahli). In both, the diagnosis of erythroblastosis fœtalis was confirmed at autopsy. The third (4·9 mgm. per cent of bilirubin in the umbilical blood) recovered from a very severe anæmia after repeated transfusions of *Rh*-negative blood.

Since jaundice and anæmia severe enough to cause death shortly after delivery may develop in infants apparently normal at birth, and since the antibody titre of the maternal blood did not always serve as an indication of the hæmolytic process in the fœtus, we consider a high value of bilirubin in the umbilical blood to be an indication of hæmolytic disease of the newborn. The presence of high bilirubin in the umbilical blood may, therefore, permit the early diagnosis of erythroblastosis fœtalis (anæmia neonatorum, icterus gravis and kernicterus).

These observations are considered to be preliminary, and a more extensive study is in progress.

Relative Activities of *l*- and *dl*-Thyroxine

We have compared the biological activities of *l*- and *dl*-thyroxine in rats receiving 4-methyl-2-thiouracil by determining the 'thyroxine requirement' as defined by Griesbach and Purves[1]. This method consists of finding the amount of thyroxine which will prevent the pituitary basophil changes, resulting from the thyroxine deficiency produced by the blockage of thyroxine synthesis by the methyl thiouracil. The thyroxine samples used were: (1) *l*-thyroxine presented by Dr. C. R. Harington, and prepared by the iodination of *l*-di-iodothyronine[2]; (2) *l*-thyroxine presented by Dr. E. P. Reineke, and prepared by acid hydrolysis of iodinated casein[3]; (3) *l*-thyroxine prepared in this laboratory from *l*-di-iodotyrosine by the method of Harington and Pitt Rivers[4]; (4) *dl*-thyroxine presented by Burroughs Wellcome and Co., and prepared by alkaline hydrolysis of thyroid substance.

The 'thyroxine requirement' of the rat was found to be 2·3 micrograms of *dl*-thyroxine per 100 gm. per day. The equivalent value for *l*-thyroxine was 1·5 micrograms per 100 gm. per day, the same value being obtained for all three samples within the error of estimation, which we judge to be ± 5 per cent.

This gives a ratio of activities $l : dl = 1{\cdot}5 : 1{\cdot}0$; a result in conflict with the ratio of 2 : 1 found by Reineke and Turner[5], who estimated the amount of thyroxine necessary to prevent thyroid-weight changes in the thiouracil-treated rat.

Autoradiography of Single Cells

The use of radioactive isotopes or tracers in the study of fundamental biological and biochemical problems has grown enormously during the last few years, and is likely to become still more important as larger quantities of various radioactive elements are made available. Certain types of problem can be solved by the application of well-known electrical methods to bulk tissue; it is recognized, however, that in any given tissue, individual cells may be in very different states or stages of development. For this reason the cytologist, in particular, wishes to study single cells. It is of interest to inquire, therefore, to what extent, if any, the photographic method of autoradiography can be applied to small organisms and single cells. It is clear from the work of Hamilton[1] and others that this technique is useful for large sections of tissue, but many other factors have to be taken into account when considering its applicability to single cells.

These factors may be stated quite simply, so long as we are only concerned with the question of detection in a given time. The problem of resolving power does not arise until conditions for detection have been proved favourable. In this note we are chiefly concerned with detection, and our calculations are based on existing data for radiophosphorus, P^{32}.

(1) *Radiophosphorus Supply.* A typical supply has an activity of 12 millicuries for a mass of 3·8 mgm. of phosphorus *immediately after irradiation.* Since 12 millicuries represent $12 \times 3{\cdot}7 \times 10^7$ disintegrations/sec., and the decay constant of P^{32} is $5{\cdot}6 \times 10^{-7}$ sec.$^{-1}$, it can easily be shown that the ratio of atoms P^{32}/P^{31} is $1 : 10^5$.

(2) *Phosphorus Content of Tissue and its Activity.* Marshak[2] has given results for the uptake of radiophosphorus by lymphoma and liver cells of mice. Our calculations are based on the values of P^{32} uptake for lymphoma cells two days after injection, when the uptake for lymphoma nuclei was greatest. On the whole, the activities of liver cells were less than those of lymphoma.

For lymphoma cells the uptake was found to be 4 per cent of the injected dose per gm. of tissue. This corresponds to an uptake of P^{32} of 0·4 per cent by weight of the total phosphorus present in the cell. The activity of the radiophosphorus supply mentioned in (1) is one hundred times the activity of that used by Marshak[2]. Using Marshak's figures, and making allowance for this fact, it can be shown that the activity of 1 gm. of tissue is 40 μc.

Suppose now that a layer of tissue one cell thick is to be autoradiographed, and that the cell has a thickness of 10 μ: the volume of cells presented to 1 sq. mm. of a photographic plate is then 10^{-5} c.c. For an activity of 40 μC./c.c. (the density of tissue is approximately unity), the activity per sq. mm. of plate is 0·4 millimicrocurie (mμC.).

(3) *Detection.* Lindsay and Craig[3], who have carried out P^{32} uptake experiments on larvæ and obtained uptakes similar to those of Marshak, mention that for X-ray film an exposure equivalent to 50 mμC./mm.^{2} was required for 1 minute. This figure has been confirmed by us in experiments using Industrex Type *D* X-ray film (Kodak) on the detection of drops of radiophosphorus solution (1 mμC. was detected and gave blackening sufficient for microphotometer measurements in 50 min.). Thus, with X-ray film an activity of 0·4 mμC./mm.^{2} would require a 2-hour exposure.

While we are here chiefly concerned with the problem of detection, the question of resolution cannot entirely be avoided, since the choice of the photographic plate is one of the determining factors. Assuming the linear dimensions of the cell to be of the order of 10 μ, a resolving power of at least 100 lines per mm. is desirable. Such plates (for example, Kodak *B*5 and *B*10) have about 1/50 of the speed of Industrex X-ray film. On this basis, an activity of 0·4 mμC./mm.^{2} would require an exposure of 4 days. The activity of the phosphorus used by Marshak (*loc. cit.*) was 1/100 of this figure, and the exposure required would, therefore, be about 40 days.

In order to make the autoradiographic technique a practicable one, a safety factor of at least 10 should be introduced to allow for (*a*) the decay of the phosphorus activity during the period of exposure, and (*b*) a certain degree of contrast in the picture to show the required detail; this, however, depends on the variation of concentration of P^{32} throughout the cell.

(4) *Conclusion.* The autoradiography of single cells having activities equal to those obtained by previous authors in experiments on bulk tissue is clearly impossible. Similar experiments carried out with more active radiophosphorus having a ratio of $\frac{\text{No. of atoms of } P^{32}}{\text{No. of atoms of } P^{31}} = \frac{1}{10^5}$, however, and using reasonably fine-grain plates, seem to be just possible. Since the possibility could only be realized in exposures lasting a few days, it is unlikely that autoradiographic techniques can be used to study migration of radioactive isotopes in single cells.

Autoradiographs should, however, be obtainable after a few hours exposure if (*a*) uptakes can be increased above the figure of 0·4 per cent, possibly by a series of injections lasting several days, or (*b*) the concentration of P^{32} in the sample of active phosphorus can be increased. Any improvements in the speed of photographic plates which may arise would also improve the possibilities of carrying out such experiments. There are obvious difficulties in maintaining biological material in a suitable condition for the long periods suggested by our calculations; moreover, no account has been taken of the biological effects of the β-radiation. Chromosomal aberrations, such as breaks and fragmentation, can readily be produced in root-tips growing in nutrient solutions containing radiophosphorus (as Miss M. Preston has recently shown in this laboratory). There are doubtless other effects; there is little point in discussing the biological implications of an experiment which on physical grounds is possible, but scarcely practicable at the present time.

I wish to thank Prof. J. T. Randall and Dr. M. H. F. Wilkins for valuable discussions.

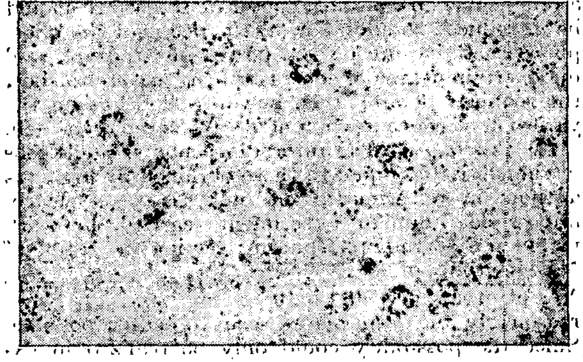
Osmophilic Granules in Chromatolytic Nerve Cells

W. A. STOTLER demonstrated at the sixtieth annual meeting of the American Association of Anatomists osmophilic granules in chromatolytic nerve cells; an account of this has been published[1]. This interesting finding is in agreement with our observations during the past few years[2]; that when using the Marchi reaction for degenerated fibres not only the degenerating myelin can be shown by the Swank–Davenport method, but also fine black granules in certain nerve cells.

Further experiments on this point strongly suggest that such a cell is one in which the metabolic processes are interfered with by cutting at some distant point its axon or its terminations. If this could be confirmed by other workers on the central nervous system, a valuable additional method of identifying interconnexions within the central nervous system would be available.



I illustrate my point by a photograph of several nerve cells of the lateral thalamic nucleus showing the black granules arranged in a ring-like formation around the cell nucleus. In this particular experiment, the motor cortex was removed on June 1, 1944, and the rabbit was killed on June 6, 1944; and in this instance the changes in the thalamus were shown after a short interval between the operation and death, while in other instances these changes could be seen even after a considerable period of time.

I should like to emphasize also that the large motor cells of cranial nerve nuclei contain after a certain interval of time chromophile granules after extensive cortical damage. This obviously cannot be explained by chromatolytic changes, and an explanation of this particular phenomenon has yet to be found.

Introduction of a Beetle from Trinidad into Mauritius to Control *l'herbe Condé* (*Cordia macrostachya*)

IN all periods of human history, inadvertently or deliberately, man has introduced plants or animals of one country into another. In some cases the consequence has been tragic, but in others his action has achieved the desired result. In the later Middle Ages the Arabs introduced into Europe many vegetables, some of which have become established; spinach, for example. In the sixteenth century the Portuguese introduced many plants and animals from the Old World to the New and *vice versa*. In modern times, however, these introductions have been for a different purpose, frequently described as 'biological control'; by which is meant that man can use a natural enemy of an organism to cause its destruction for him. But this method has not always been successful because not all the factors that are involved in such transfers from one place to another are known, and, perhaps, not all of them can be completely known. But, so far as they can be known, they ought to be taken into consideration.

My attention has been directed to the fact that a batch of *Physonota alutacea* Boheman (Cassidinæ, Coleoptera) has been recently introduced into Mauritius; which, it is hoped, will eat *l'herbe Condé*—*Cordia macrostachya*, Roem. and Schult.—to such an extent that its unimpeded propagation will be checked. It should be remembered that this plant itself has been accidentally introduced into Mauritius.

Physonota alutacea Boheman occurs in Mexico, Central America, Venezuela, Colombia and Ecuador. It has also been found in San Francisco, Trinidad and the Galapagos Isles.

Physonota and other related genera belong to the New World and do not occur in the Old World. The Old World genus which is equivalent to *Physonota* is *Aspidomorpha*, and this does not occur at all in the New World. *Physonota* and its allies correspond to *Aspidomorpha* and its allies in general structure and habits so remarkably that one cannot help feeling that they must have descended from a common ancestor. From this relationship I assume that whatever food habits one group may have the other group probably will have.

The cassidine beetles have been known to eat plants of 26 out of 320 families as shown in the tables of my book (not yet published); the greatest number occurring on the Convolvulaceæ and the Compositæ. The beetles of the genus *Physonota* actually eat the following plants—Compositæ: *Helianthus* (sunflower), *Sonchus* (sowthistle); Boraginaceæ: *Cordia macrostachya*. In addition to *Physonota*, other New World cassidine beetles (*Coptocycla adamantica* Germer and *Cistudinella obducta* Boheman) have also been found on *Cordia*. It is important to remember this, since it means that if one species shows a taste for *Cordia* there are others which will have the same taste.

In the Convolvulaceæ the genera most attacked by cassidine beetles are *Convolvulus* and *Ipomœa* (sweet potato), and both Old and New World species of the Cassidinæ have been found on them. Therefore, although *Physonota* has not been actually found on the plants of these two genera, it is quite probable that *Physonota* will eat them.

The Old World genus *Aspidomorpha* occurs on *Argyreia* and *Quamoclit*—two genera also of the Convolvulaceæ. Three species of *Chelymorpha*, a New World genus allied to *Physonota*, have been found on three species of *Solanum* (Solanaceæ), including the potato. Three species belonging to two other genera of the New World have also been known to eat plants of *Solanum*. It seems likely, therefore, that *Physonota*, too, may feed on *Ipomœa* and *Solanum* as well as on *Cordia*.

Among the Gramineæ, both *Zea Mays* and *Saccharum* (sugar-cane) are attacked by *Chelymorpha*, the former also by a species of *Cassida*, a genus occurring in both New and Old Worlds; *Chirida*, another New World cassidine genus, also feeds on sugar-cane.

It is important to note that *Chelymorpha*, closely related to *Physonota*, has at least one species which is capable of eating the sugar-cane plant, and it is in the sugar-cane plantations that *Cordia* has become a nuisance. It is hoped that the introduced *Physonota* will behave as it is expected to do; but warning should be given that it may take a liking to sugar-cane, and even to the potato and sweet potato.

Record of an African Fodder Grass from Central Burma

A NUMBER of exotic plants occur in the dry zone of central Burma. The annual rainfall of this area is only 25–35 in. in one monsoon, and the general vegetation is predominantly xerophytic—such as thorny shrubs, succulent species of *Euphorbia* and ephemerals. Some of these foreign plants are so well established that they could easily be mistaken for indigenous plants.

One of the common grasses of this dry zone is a scandent drought-resistant fodder grass, usually found trailing over thorny shrubs and common in hedgerows. This grass was sent to Kew in 1942, and has been identified by Mr. C. E. Hubbard as *Urochloa mosambicensis* (Hackel) Dandy[1]—a native of Central and East Africa. Other synonyms by which this grass is known are *Panicum mosambicense* Hackel[2], *Panicum notabile* Hook.f.[3] and *Echinochloa notabile* (Hook.f.) Rhind[4]. Both Hook.f. and Rhind expressed their doubts as to its affinities under the genera *Panicum* and *Echinochloa*, and Rhind contrasted its xerophytic characters with other species of *Echinochloa* of Burma.

On account of its value and possibilities as a fodder, this grass has attracted attention in Africa and Burma independently. It has been also introduced in Australia (Queensland), where it is said to be thriving well. It must have reached Burma very early, as Wallich collected it near the oilfields around Yenangyang in 1826 (Wall. Cat. 8723). Intentional introduction before Wallich's time is extremely unlikely, as traffic between the coasts of East Africa and Burma in those days was always scanty. Nevertheless, this appears to be the only possible route, as the plant is not recorded so far either from India or Malaysia. It is also not known how the plant reached Central Burma from the port (Rangoon), traversing the belt of heavy rainfall and swampy areas quite unsuitable for its growth. Most probably this took place accidentally, and the seeds must have been carried by river boats up the Irrawadi to the dry areas of central Burma, where the plant established itself.

Errors of Estimation in Inverse Sampling

IF a random sample of N individuals is taken from a population in which a proportion $P(= 1 - Q)$ possess a certain attribute, and of these N are found to possess the attribute, then, as is well known,

$$p = a/N$$

is an efficient and unbiased estimate of P. The variance of p is PQ/N; but unless N is large neither this quantity nor an estimate of it can be used directly in order to assign fiducial limits to p. If a probability level, say 0·05, is selected, upper and lower fiducial limits, p_U and p_L, may be defined; these are such that if P were equal to p_U, the probability of obtaining a or less individuals with the attribute in a sample of N would be 0·025, and if P were equal to p_L, the probability of obtaining a or more in a sample of N would be 0·025. Evaluation of p_U and p_L by successive approximation and summation of terms of a binomial expansion is tedious, but a table by W. L. Stevens[1] enables these 'true' limits to be obtained rapidly with sufficient accuracy for most practical purposes.

An alternative method of estimating P, that of *inverse sampling*, has been suggested as possessing advantages in some circumstances. This consists in taking individuals at random until a specified quota, A, possessing the attribute has been obtained. If this requires a total sample of n, the estimate of P is

$$p = (A - 1)/(n - 1);$$

the variance of p is approximately

$$s_p{}^2 = p^2q/(A - 2),$$

but s_p cannot be used for assigning fiducial limits to p except in large samples.

It may not have been generally realized that methods and tables for determining true fiducial limits for direct sampling may be adapted very easily to inverse sampling. For if p_U is the upper limit to a value of p estimated from inverse sampling, by definition it is the value of P for which the probability of obtaining the quota, A, in n or more trials is 0·025; this is the same as the value of p which, in direct sampling, would give $(A - 1)$ or less with the attribute in a sample of predetermined size $(n - 1)$. So p_L, the lower limit, is the value of P which would give the quota in n trials or less with a probability of 0·025, and is therefore the same as the value of p which, in direct sampling, would give A or more with the attribute in a sample of n. Hence the rule may be stated: in inverse sampling, the upper fiducial limit is the same as the upper limit for a direct sample with $N = (n - 1)$, $a = (A - 1)$, and the lower fiducial limit is the same as the lower limit for a direct sample with $N = n$, $a = A$. Stevens' table, entered according to his rules with the appropriate values of N, a, will then give the fiducial limits.

Haldane[2,3] has pointed out that, when p is small, its standard error in inverse sampling is practically a constant proportion of p for any fixed value of

Hence, by choice of a suitable value of A, the proportional standard error may be selected in advance of the sampling, a requirement which cannot be satisfied in direct sampling. Stevens' table records the limiting values of Np. For a fixed a and a fixed probability level, these are nearly independent of p, particularly for p less than 0·2; consequently, if P is known to be small, for any specified A, inverse sampling will give a value to $(p_U - p_L)/p$ almost independent of p. Hence, by suitable choice of A, the magnitude of the fiducial range relative to the estimate p may be determined approximately in advance of the sampling.

Application of the Method of Steepest Descents to X-Ray Structure Analysis

ALTHOUGH the Fourier method of synthesis has enjoyed a long and justified supremacy in the armoury of techniques for X-ray structure analysis, the time is rapidly approaching when its use will be limited by the complexity of the structures investigated. In the absence of any universally applicable method of obtaining phase angles, Fourier refinement can be applied only to those structures which are sufficiently simple for an accurate estimate of their parameters to be made. It is an unfortunate fact that the Fourier refinement process converges only if the trial parameters are reasonably close to the true ones, and the region of convergence is roughly that of the differential method[1].

Even when the general shape and disposition of the atoms in a molecule are known, it is often extremely difficult, using only trial and error or Patterson–Harker methods, to find the proper location of that molecule in the unit cell, and it is evident that a first step towards a unified treatment of structure analysis would be a means of treating such groupings as a whole. The methods of molecular transforms[2] cannot be regarded as a satisfactory solution to this problem since, as soon as the space-group symmetry becomes at all complicated, they become difficult or impossible to apply.

A third feature which would be desirable is some means of refining density distributions. This is particularly the case with biomolecular substances since, although in general it is impossible to make even a conjecture as to their detailed structure, it may be possible to form a reasonable estimate of their general shape[3].

The purpose of this note is to explain briefly the application of the method of steepest descents to the above problems. The detailed techniques have been worked out and will appear in full elsewhere, but sufficient detail will be given here to allow of the application of the method in its simplest form.

Suppose that a set of observed structure factors $F_0(h,k,l)$ is given, then a set of atomic co-ordinates is called a correct structure if:

(1) $R=\Sigma \,\|\, F_0 \,|-|\, F_c \,\|$ or $R_2 = \Sigma\ (F_0^2 - F_c^2)^2$ is a minimum.

(2) The structure is not impossible on stereochemical grounds.

It is possible that a structure, correct from this point of view, may not be unique. If this is the case, however, there is no means of telling which of several structures, having the same minimum value of R or R_2, is the real one. So that the point is one of philosophical interest only.

Suppose that a set of trial parameters x_{rj} ($r = 1,2, - N$; $j = 1,2,3$) is given, the problem is to vary them so as to minimize R_2 in the most rapid manner. Now the equation R_2 = const. represents some surface in the $3N$ dimensional space defined by the x_{rj}. The method of steepest descents simply specifies a procedure for moving from this surface to another having a smaller value of R_2. Starting from the point x_{rj} on $R_2 = C_1$, move in the direction of the normal to this surface until R_2 stops decreasing. Having arrived at this point on some surface $R_2 = C_2$, repeat the procedure. Evidently (neglecting cols and other singularities discussed elsewhere) the process converges to a minimum value of R_2, and the co-ordinates of this minimum are the required atomic parameters.

The analytical expression for the change ε_{rj} in any co-ordinate x_{rj} is simply:

$$\varepsilon_{rj} = -[\sum_{rj}\ (\partial R_2/\partial x_{rj})^2] \, . \, (\partial R_2/\partial x_{rj}) / \sum_{rj,r'j'} (\partial^2 R_2/\partial x_{rj}\partial x_{r'j'}) \, . \, (\partial R_2/\partial x_{rj}) \, . \, (\partial R_2/\partial x_{r'j'}), \qquad (1)$$

the derivatives being easily determined from the expression for R_2 and the algebraic form of $F(h,k,l)$.

In the early stages of a refinement it is usually easier to use the expression:

$$\varepsilon_{rj} = -\,2R_2 \, . \, (\partial R_2/\partial x_{rj}) / \sum_{rj} (\partial R_2/\partial x_{rj})^2; \qquad (2)$$

this requires care, however, as it leads to incorrect results when the x_{rj} are near their optimum values. As a practical rule, (2) should be used until a point is reached at which R_2 increases.

Similar expressions apply to R; but in this case particular care has to be exercised owing to the discontinuous nature of the moduli.

Despite the unpleasant appearance of (1) and (2), the calculations are quite easy, and much shorter than those of the Fourier method. As an example, the method was applied to the oxalic acid data and, starting from a *random* set of z parameters, the correct values were derived in three refinements which took only two and a half hours.

Application to the case of a known molecular shape is also easy; here the co-ordinates in some fixed set of axes are evaluated, and the whole frame of reference is rotated and translated until R or R_2 is minimized. The variables in this case are (x_0,y_0,z_0)—the co-ordinates of the origin, and (η,λ,μ)—the angles of rotation. Other applications cover the case where the molecule consists of a number of known groups, each of which can be treated as rigid.

Another modification of the method enables the molecule to be defined as a series of densities at lattice points; these densities are then varied to give a minimum value of R or R_2.

It is interesting to note that the method of least squares is a special case of the steepest descent technique, and is derivable from the same basic analysis.

Effect of Bending on Selenium Rectifier Disks

BENDING a selenium rectifier disk causes a temporary increase of the current flowing through it in both directions. The effect (discovered in December 1942) is especially pronounced in the reverse direction, where a momentary increase of the current intensity up to 300 per cent and more can be produced through bending by hand, while in the forward direction values exceeding 5–10 per cent have not been observed. With copper oxide rectifiers no trace of a similar effect could be detected. The following, mostly qualitative, observations were made on our own disks, in the reverse direction: (1) The bending causes an increase of the current, whether the selenium layer lies on the convex or on the concave side of the disk. (2) In general, the stronger the bending the greater the effect. (3) The increase of current is, at its maximum, a temporary one. After bending a disk with a constant force, the momentary increased current intensity diminishes in the first few seconds rapidly, then slowly, and reaches its end value after some minutes. The behaviour of the disk is then, within certain narrow limits, that of a biased system: an increase of the bending increases also the current and *vice versa*. (4) Temperature has a pronounced influence; at 40–50° C., the effect is essentially smaller, and it seems to disappear more rapidly than at room temperature. (5) The effect depends upon the applied voltage. While at small voltages (1–2 volts) no effect is observable, with increasing voltages it increases also rapidly and reaches a maximal value as high as 350 per cent at 15–20 volts with some disks.

Selenium is a typical semi-conductor, its conductivity being due to the faults of the crystalline structure and to the impurities contained in it. Some of these centres are dissociated (into electron holes and negative ions) already in the mechanically finished disks, before forming, and determine the electrical properties of the disk at room temperature and below 1–2 volts. Further ionization—or expressed with modern terminology, transition of electrons to a conductivity-level—can be effected: (*a*) with thermal, (*b*) with electrical, and (*c*) with electrical plus mechanical energy. Thermal ionization goes on with any increase of temperature in the whole selenium layer and causes the temperature coefficient of the conductivity in the forward direction to be positive. Processes (*b*) and (*c*), however, take place only in the blocking layer, where an electrical field strong enough can be produced, thus explaining (*b*) the decrease of reverse resistance with increasing voltages and the phenomenon of 'electrical forming', with respect to (*c*) the bending effect.

In brief, we ascribe the bending effect to the dissociation of the impurity centres under the simultaneous action of electrical field intensity and the shearing stresses, impressed on the selenium layer by the bending. This assumption, together with the phenomenon of plastic relaxation, explains all the observations enumerated above.

Those interested in the new effect are invited to write for free samples of rectifier disks to the address below.

Transformation of Trichromatic Distribution Curves

The purpose of this communication is to bring to attention a point which does not seem to be generally realized although it is quite simple to prove. If one of a set of three colour-matching stimuli is altered, *the distribution curve for that stimulus is not changed,* though one or both of the other two distribution curves is altered.

Consider a colorimeter in which white is matched by a mixture of one trichromatic unit each of three stimuli X, Y and Z. If some of the stimulus X is transferred from its own beam to the Y beam, we shall have a new primary G; but since the match with white is unaffected, one trichromatic unit each will be present in the new system of X, G and Z. Since one unit of G contains one unit of Y, and also some X, it follows that in matching any colour with a mixture of X, G and Z the same number of units of G will be required as of Y in a mixture of X, Y and Z. The amounts of Z required in the two systems will be the same, though the amounts of X will be different. Therefore, the spectral distribution curve of X will be altered but that of G will remain the same as that of Y.

Let $\bar{x}$, $\bar{y}$ and $\bar{z}$ be the spectral distribution coefficients of stimuli X, Y and Z, and $\bar{r}$, $\bar{g}$ and $\bar{b}$ those of a new set of stimuli, R, G and B, the trichromatic coefficients of which in the X, Y, Z system are u_1,v_1,w_1; u_2,v_2,w_2; u_3,v_3,w_3; where $u + v + w = 1$. Then where

$$\frac{\bar{x}}{\bar{x}+\bar{y}+\bar{z}} = u_1, \quad \frac{\bar{y}}{\bar{x}+\bar{y}+\bar{z}} = v_1 \text{ and } \frac{\bar{z}}{\bar{x}+\bar{y}+\bar{z}} = w_1,$$

the following relations must hold:

$$\frac{\bar{r}}{\bar{r}+\bar{g}+\bar{b}} = 1, \quad \frac{\bar{g}}{\bar{r}+\bar{g}+\bar{b}} = 0, \quad \frac{\bar{b}}{\bar{r}+\bar{g}+\bar{b}} = 0,$$

so that $\bar{g}$ and $\bar{b}$ must both be zero.

Similarly, if $\dfrac{\bar{x}}{u_2} = \dfrac{\bar{y}}{v_2} = \dfrac{\bar{z}}{w_2} = \bar{x} + \bar{y} + \bar{z}$, $\bar{r}$ and $\bar{b}$ must both be zero, etc.

If the same white-point is adopted in the two systems, then $\bar{r} = \bar{g} = \bar{b}$ when $\bar{x} = \bar{y} = \bar{z}$; hence we can derive the transformation equations:

$$\bar{r} = \frac{\begin{vmatrix} \bar{x} & \bar{y} & \bar{z} \\ u_2 & v_2 & w_2 \\ u_3 & v_3 & w_3 \end{vmatrix}}{\begin{vmatrix} 1 & 1 & 1 \\ u_2 & v_2 & w_2 \\ u_3 & v_3 & w_3 \end{vmatrix}}; \quad \bar{g} = \frac{\begin{vmatrix} u_1 & v_1 & w_1 \\ \bar{x} & \bar{y} & \bar{z} \\ u_3 & v_3 & w_3 \end{vmatrix}}{\begin{vmatrix} u_1 & v_1 & w_1 \\ 1 & 1 & 1 \\ u_3 & v_3 & w_3 \end{vmatrix}}; \quad \bar{b} = \frac{\begin{vmatrix} u_1 & v_1 & w_1 \\ u_2 & v_2 & w_2 \\ \bar{x} & \bar{y} & \bar{z} \end{vmatrix}}{\begin{vmatrix} u_1 & v_1 & w_1 \\ u_2 & v_2 & w_2 \\ 1 & 1 & 1 \end{vmatrix}}.$$

It will be seen that $\bar{r}$ is independent of u_1, v_1 and w_1; that is, of the position of R. If only one, say G of R, G and B, is different from X, Y and Z we have $u_1 = w_3 = 1$, $v_1 = w_1 = u_3 = v_3 = 0$, and the equations reduce to:

$$\bar{r} = \frac{v_2\bar{x} - u_2\bar{y}}{v_2 - u_2}; \quad \bar{g} = \bar{y}; \text{ and } \bar{b} = \frac{v_2\bar{z} - w_2\bar{y}}{v_2 - w_2}.$$

Moreover, if G is somewhere on the line XY, so that $w_2 = 0$ and $u_2 = 1 - v_2$, we have:

$$\bar{r} = \frac{v_2\bar{x} - (1-v_2)\bar{y}}{2v_2 - 1}; \quad \bar{g} = \bar{y}; \text{ and } \bar{b} = \bar{z}.$$

In other words, altering the green primary alters only the red and blue distribution curves, and if the green is moved along the red-green line the red distribution curve alone is changed.

It is perhaps of interest to note further that if in the last equation $v_2 \rightarrow \infty$, then $\bar{r} \rightarrow \frac{\bar{x} + \bar{y}}{2}$.

I wish to thank Mr. E. W. H. Selwyn and Dr. W. D. Wright for helpful comments.

Combination Tones

FROM time to time attention has been given to the objective reality of so-called 'combination tones' produced when two simple tones are sounded together. We have recently had an opportunity of investigating this experimentally, using a wave analyser of the degenerative type, employing an electronic circuit described by one of us[1]. The analyser has a high selectivity corrresponding to a Q value of about 100.

An approximately sinusoidal voltage at a frequency of 1,025 c./s. was superimposed on another approximately sinusoidal voltage of frequency 735 c./s., the r.m.s. amplitudes being 200 mV. in each case. Search was made for the difference frequency (290 c./s.) and the summation frequency (1,760 c./s.), and these were found to be practically non-existent. The strength of the 290 c./s. component was about 1 mV., and the summation frequency was too weak to be measured, although its presence was detected.

The analyser was designed to handle a total of 500 mV. (with the particular attenuator setting used in the experiment) with minimum distortion. Nevertheless, some slight distortion is to be expected which would give a rectifying effect and would probably account for the traces of combination tones which were observed.

The two input signals were simply added linearly, and quite different results would be expected if the amplitude of one tone were modulated at the frequency of the other.

Sublimation in Outdoor Air

IN a previous communication[1], experiments were described on the sublimation of water vapour in a Wilson chamber. It was found that in clean air sublimation commences only at temperatures below $-41{\cdot}2° \pm 0{\cdot}05°$ C., whereas in outdoor air at Oxford this threshold temperature is 9° C. higher.

With the view of investigating conditions at cloud-level, the Air Ministry arranged for me to visit the Hochalpine Forschungsstation at Jungfraujoch, which is 11,680 ft. above sea-level.

During tests lasting three weeks (April 1947) the threshold temperature there was found to be $-41{\cdot}2° \pm 0{\cdot}05°$ C., with the exception of two days, on which it rose to $-38°$ C. The air at Jungfraujoch during these two days was exceptionally hazy. On April 13 (the first occasion) there was an anticyclonic inversion which had developed during the previous night. On the second occasion, April 27, there was an exceptionally strong wind with general instability of the air mass.

It thus appears that whatever sublimation nuclei are effective in the lower air are usually absent from air at the height of Jungfraujoch.

This work is published by permission of the Director of the Meteorological Office.

Silicon Flame Bands

WE have recently made a preliminary study of the visible spectrum of flames of hydrogen charged with silicon tetrachloride burning in air. In a Méker burner with restricted supply of air, grey-blue cones are developed, and spectrograms of these taken on a low-dispersion prism instrument show a number of bands, apparently degraded to the violet, in the range 4200–5700 A. The strongest head is at about 5240 A., and a tentative vibrational analysis gives $\omega'' \sim 750$, $\omega' \sim 1050$ and $\nu_e \sim 19{,}000$ cm.$^{-1}$.

The circumstances in which these bands are produced suggest that the emitter may be Si_2, and the provisional values of the constants given above do not conflict with this view; but unambiguous identification must await the results of a detailed study with instruments of higher dispersion. This work is in progress.

What is a Dialysate ?

THE "Oxford Dictionary" defines 'dialysate' as that portion of a mixture that remains after dialysis, and quotes Attfield's "Text-book of Chemistry" (1885). The quotation shows that the part that fails to pass through the membrane is referred to. From the point of view of the lexicographer, this is perfectly satisfactory; there seems to have been no earlier use of the word in print. Graham, for example, although he coined the word 'dialyser' and gave a new meaning to the word 'dialysis' did not apparently use 'dialysate'.

Present-day usage does not agree with the "Oxford Dictionary". Nearly all the biochemists that I have consulted have understood by dialysate the more diffusible part of the system. At present, therefore, the word is ambiguous unless the context makes the meaning clear. Many authors and editors have not read Attfield, and some of those who have may question his authority in the matter. The popular meaning has probably been adopted because of the analogy with filtrate, distillate, sublimate, etc.; in each case the more mobile part of the system is referred to. The continuing existence of this analogy will make it difficult to get universal acceptance of the dictionary meaning of dialysate.

We are left with no word except colloid for the part of a system that is retained by the dialysis membrane. This is unfortunate, but it is better than ambiguity.

BRITISH SCIENTIFIC INSTRUMENT RESEARCH ASSOCIATION

OPENING OF NEW LABORATORIES

A NEW chapter in the history of the British Scientific Instrument Research Association commenced on July 10, when the new laboratories of the Association at "Sira", Southill, Elmstead Woods, Kent, were formally opened by the Minister of Supply, the Right Hon. John Wilmot. The Association, which was founded in 1918, has been for many years handicapped by its limited resources and facilities. At the time of the inauguration of the Association, it could not do more than adapt a house in Russell Square, London, to laboratory use, and the limited facilities which were established there compelled the Association to direct its activities into certain well-defined channels of restricted operation. These circumstances made it difficult to attempt to establish a membership representative of all scientific instrument interests, and in consequence the Association has in the past prosecuted researches which, although extremely valuable to the particular interests served, have not ranged over the total requirements of the industry. From the commencement of the rearmament programme, many firms not in membership with the Association extended the scope of their activities to an extent which brought them within the field of research covered by it, and in consequence the membership, which at that time included twenty-five instrument firms, rapidly increased to more than one hundred. At the conclusion of the War, the Council of the Association formulated a scheme of expansion to permit it to meet the research needs of the enlarged membership in an adequate manner. This scheme was approved by the Department of Scientific and Industrial Research, which offered very considerable practical support, and it has now come to fruition.

The enlarged Association consists of six Experimental Departments and an Information Department. The Association was fortunate in acquiring a mansion at Elmstead Woods, Kent, which, by reason of the number and size of its rooms, was admirably suited to the experimental purposes of a research association. The work of conversion has been completed, and the experimental activities of the Association have now been transferred to the new laboratories at Elmstead Woods, situated in five acres of grounds in very beautiful surroundings, where the conditions of working are almost ideal.

Optical Instrument Department. A predominant feature of the past activities of the British Scientific Instrument Research Association has been work on problems associated with optical instrument production. While the Optical Department now takes its place as one of several, the facilities for this branch of the work have, in fact, been increased. The space devoted to optical work at Russell Square is now occupied by the Computing Section of the Department; while in the new premises a general optical laboratory has been established, ample provision has been made for the work on graticules and allied problems, and room has been set aside for interferometers and other standard testing equipment. The work of the Department can now expand beyond that connected with the processes and the materials used in manufacture to the investigation of problems of the actual instruments and to the development of new types.

Chemistry Department. Chemical research plays no small part in the activities of the Association, and the importance of this branch of the work is reflected in the excellent chemical laboratories to be found at "Sira". The old ballroom has been converted into a spacious general laboratory which is very completely equipped. In addition, two smaller laboratories provide facilities for specialized researches. The making of experimental melts of technical glasses, which has always been a main feature of the work of the Association, will be continued in a new glass-founding shop set up in an outhouse formerly used as a domestic laundry.

Physics Department. Many of the investigations undertaken by the Association are best carried out in orthodox physical laboratories. Three of the new laboratories have been allocated to physics; one is a large general physical laboratory, another is devoted to work involving high vacua, while the third has been set aside for special independent research.

Electrical Instruments Department. The Association has for many years included among its membership some manufacturers of electrical instruments; but experimental work carried out on their behalf has been limited to such as could be covered by normal chemical and physical laboratory facilities. There is no more heartening aspect of the expansion of the Association than that it permits problems peculiarly associated with electrical instruments to be investigated with adequacy. New laboratories have been equipped bearing especially in mind the needs of the electrical instrument membership, and benefits should accrue to this class of member on a scale far larger than was possible in the old circumstances.

Electronics Department. Electronics have in recent years made a very considerable incursion into the field of instrument design. Laboratories have been established in the new premises, which are equipped in a manner most suitable to the carrying out of investigation of problems arising through the application of electronics to scientific instruments. Any work carried out in the past by the Association in this connexion has been prosecuted under conditions of improvisation. The new laboratories have been planned and equipped specifically to meet the requirements of this branch of the Association's work.

Mechanical Department. The investigation of mechanical problems has not in the past fallen within the purview of the Association, and in consequence there has existed a wide gap in the service it has been possible to render to the makers of mechanical instruments or, in respect of their mechanical problems, to instrument makers in general. It is therefore most appropriate that mechanical facilities have been provided under the new scheme. A mechanical laboratory equipped with modern machine tools has been established, drawing office facilities are now available, and a modern workshop is in process of completion.

Information Department. The first fruits of the scheme of expansion was the establishment of a comprehensive Information Department and Library, which remain at Russell Square. The work of abstraction from numerous technical journals, incorporated in the monthly *Bulletin*, the provision of information on a very wide range of subjects, the library facilities, with its lending arrangements, have already proved of great benefit to the membership and to the research staff of the Association.

Such is the present position of the Association, which is looking forward to achieving on behalf of the scientific instrument industry as a whole even more beneficial results than those which in the past have been enjoyed by a restricted section of the industry. Every branch of instrument making is now effectively represented in the membership of the Association, and the opportunity exists for the influence of the Association to spread in many new directions. In his speech at a luncheon which followed the opening ceremony, the Minister of Supply remarked, "The instrument makers look to the Association for help in solving their problems and overcoming their difficulties. From what I have learned of the Association, they will get this help. The member-firms of the Association are supplied with a monthly *Bulletin* dealing with the latest results in research and development, and there is, in addition, a fund of technical information available in the excellent Library maintained by the Association. The achievements of the Association are far too many to enumerate; but I was interested to learn that nearly two hundred research reports have been issued by the Association, and these, I know, are of great interest to the manufacturers. The British Scientific Instrument Research Association is the oldest surviving research association connected with the Department of Scientific and Industrial Research, having been formed in 1918, when it had no more than nine members; to-day the membership exceeds one hundred. The Association's record is such that with the greatly increased facilities at Elmstead Woods it will be surprising if the present membership is not increased in the near future. The Association has already contributed greatly to the tools and instruments which have established the good name of British workmanship in the past, and I am sure it will maintain and even improve this reputation. . . . I would like to express the gratitude of the Government in general and of my own Ministry in particular for the great achievements of the Association in the past."

POLLUTION BY TRADE WASTES FROM FOOD INDUSTRIES

THE cause and effects of pollution by waste waters from food industries, and the prevention of this pollution, were discussed by Dr. B. A. Southgate and Dr. S. H. Jenkins at a joint meeting of the Food Group of the Society of Chemical Industry and the Midland Section of the Society held at Birmingham on May 23; Mr. T. Rendle presided.

Some waste waters contain directly toxic substances such as cyanides, phenols, and metallic compounds; in wastes from the food industries, however, pollution is due mainly to organic matter in solution and in suspension. Organic matter discharged into a stream is oxidized by bacterial action at the expense of the oxygen dissolved in the water. The rate of oxidation increases with rise in temperature; consequently a rise in temperature causes a decrease in the concentration of oxygen dissolved in the water, because this is the result of an equilibrium between the rate at which it is used in processes of oxidation and the rate at which it is absorbed from the atmosphere. As an illustration, in the winter the polluted estuary of the River Tees may contain dissolved oxygen equivalent to 70–80 per cent of the amount required to saturate the water, whereas in summer the corresponding concentration may be as little as 0 to 10 per cent of the saturation value. If the content of dissolved oxygen falls below about 50 per cent of the saturation value, the water may be unsuitable for fish, though they can live at much lower concentrations, particularly at low temperatures, at least for comparatively short periods.

Other effects of discharge of waste waters from the food industries include the deposition of organic sludge which may undergo anaerobic fermentation in warm weather, and which may cause marked changes in the distribution of bottom-living invertebrates, many of which serve as food for fish. Discharge of organic matter may also lead to the growth of 'sewage fungus'; this term is applied to a wide variety of Bacteria, Fungi, and Protozoa or associations of them, usually whitish-grey in colour and resembling cotton wool in appearance. These growths are found adhering to vegetation and stones in many polluted streams, and usually cause silting on the river bed. When the fungus dies it is decomposed by bacterial action, with absorption of oxygen from the water and sometimes with evolution of hydrogen sulphide.

Waste waters from food industries may cause difficulty in the use of surface waters for domestic supply; the presence of organic matter may make the water unpalatable; ammonia may interfere with the treatment of water by chlorination; and nitrogenous compounds may stimulate growth of Algæ which cause difficulty in sand filters and may also give rise to unpleasant tastes.

When the construction of a food factory is being planned, the possibility of pollution resulting from trade effluents must be borne in mind. Pollution is sometimes avoidable by erecting factories where sewers and sewage disposal works are at hand to deal with any waste water. When vegetables or fruit must be conveyed to a factory in a fresh condition, this is not always possible, and treatment of the waste water at the factory then becomes necessary.

The volume of waste water produced and its impurity content varies greatly from factory to factory, depending upon the product made, the management, and the amount of water available for processing. The organic matter in the waste water can be expressed in terms of an equivalent amount of domestic sewage and therefore in terms of population. For example, a beet sugar factory handling 1,000 tons of beet daily may discharge up to four million gallons of waste water daily, containing organic matter equivalent, in some cases, to the sewage from about 2,000 persons and in other cases to the sewage from 20,000 persons. Food wastes show marked fluctuations in the polluting matter content because processing varies with the time of year: a tenfold increase in the polluting strength of the waste water within a matter of a few weeks is not at all uncommon. This variation in strength, and also the fact that the waste water is frequently produced over a short period of the day, introduces difficulties in designing treatment plants for purifying the factory wastes.

The methods used for purifying food wastes have developed from those employed for sewage treatment. Fibrous matter, rootlets, peelings, etc., are removed by passing the water through screens; suspended mineral matter is then separated and the organic matter in suspension removed by continuous passage through sedimentation tanks. The residual polluting matter in solution is eliminated by biological oxidation by: (1) allowing the liquid to percolate through suitable soil; (2) distributing it over a filter bed made of inert material resting on a well-drained floor, so as to cultivate on the inert material a flora and fauna able to oxidize the organic impurity in the waste water; or (3) aerating a mixture of the waste water and a heterogeneous culture, known as activated sludge, which consists of organisms grown from the waste water.

All pollution prevention authorities agree that industrial wastes are best treated at sewage purification works. The Public Health (Drainage of Trade Premises) Act, 1937, gives manufacturers the right to use public sewers and sewage works for disposing of trade wastes, provided they do not injure structural materials or inhibit purification. Some food wastes, especially those from the fermentation industries, may cause very serious interference with treatment of the sewage when present in high concentration, but ordinarily the difficulties encountered are surmountable.

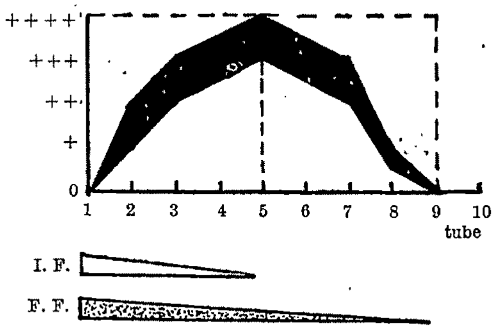
In discussion of the two papers, it was stated that the growths in a river receiving beet sugar waste had caused trouble on the screens at an electric power station ten miles below the factory. Wastes containing sugar favour such growths over a long stretch of river in cold weather: in warm weather, the sugar is rapidly oxidized and so the region of pollution is smaller, though the extent of pollution is greater. Decomposition of solid matter on the bed of a stream was also discussed. Anaerobic organisms break down such matter into gaseous products, or into substances which are then oxidized by aerobic organisms. The effects of Algæ were also mentioned. During the day, photosynthesis by Algæ raises the dissolved oxygen concentration in rivers, and when algal growth is marked, there is a diurnal variation in the dissolved oxygen content of the water. A prolific growth of Algæ might be followed by a lowering of the dissolved oxygen in the water when the Algæ die and decompose.

Further discussion was concerned with methods of analysis, means for assessing the amount of polluting matter in waste water, the treatment of wastes by means of chemical precipitants, the disposal of the sludge or solid matter in waste water, the dissolved oxygen content of sea water, and the difficulty of obtaining supplies of constructional materials for trade-waste purification plant.

A NON-SPECIFIC RESISTANCE FACTOR IN THE ALBUMIN RESIDUE REVEALED BY THE SERIAL CEPHALIN FLOCCULATION CURVE

By Dr. JACK G. MAKARI
Department of Bacteriology, American University of Beirut, Lebanon

IN the last laboratory meeting of the Royal Society of Tropical Medicine, I demonstrated the various types of serial cephalin flocculation curves as obtained in health and disease with a special reference to their application in tropical derangements. In obtaining the curves, the serial dilution method was followed[1], using ten tubes instead of Hanger's original one-tube method[2]. Serial cephalin flocculation curve I, shown in the accompanying figure, represents the normal range in fifty healthy volunteers. In a study of the mechanism of Hanger's test, which is comparable to the first tube in the serial dilution method, Kabat, Hanger *et al.*[3] found the flocculating factor to be associated with the γ globulin. They failed, however, to find an inhibiting fraction in the albumins. Moore, Pierson *et al.*[4], two years later, reported from the same laboratory the presence of an inhibiting fraction associated with the albumins. It is to be noted that these workers were using electrophoresis by means of which albumins appear homogeneous[5]. Dennis and Makari[6], using salting-out methods, found the greatest concentrations of this inhibiting factor in the albumin residue. Since this inhibiting factor was found by the latter workers to be originally present in the serum in smaller amounts than the flocculating factor, the critical dilution-level of 0·04 mgm. is reached much earlier in the case of the inhibiting factor. The first zone representing the first five tubes in the figure presents, therefore, a delicate balance between flocculating factor (γ globulin) and inhibiting factor (albumin residue). In the second zone only the former is at work. This delicate balance in this first zone represents as well a balance between the liver and reticulo-endothelial system.



Further study of this inhibiting factor present in the albumin residue of man and revealed by the first zone of the serial cephalin flocculation curve shows that it plays an important part in relation to drug administration, immunization, relapse and the outcome of infection in man.

The figures in the tables indicate the extent of deviation of this inhibiting factor from the normal range in health (serial cephalin flocculation curve I) recorded in ⅛ in. square units. A deviation below the normal curve, that is, an increase in inhibition, is designated as positive, while a deviation in the opposite direction is designated as negative. Reference to the dosage is made as follows: for quinine up to 3 gm. as small dose, 3–6 gm. as medium dose, and more than 6 gm. as large dose; for atebrin up to 0·6 gm. as small dose, between 0·6 and 1·2 gm. as medium dose, and larger amounts than 1·2 gm. as large dose.

Vaccination with T.A.B. was accomplished by the subcutaneous administration of 500 million bacteria; a double dose was given one week later and repeated one week later still. The typhoid cases studied were reported earlier in relation to Hanger's test[7].

No reference is made in this preliminary report to changes in the flocculating factor which reflect reticulo-endothelial stimulation. This latter aspect will be referred to in the detailed report.

It is apparent from Table 1 that both quinine and atebrin give rise in healthy volunteers to a positive inhibiting factor response; atebrin resulting in greater stimulation over a shorter period.

A transient positive inhibiting factor response is also observed as a very early manifestation of

TABLE 1

	Treatment given	Deviation of I.F. response from normal S.C.F. curve I				
		Before treatment	After small dose	After medium dose	After large dose	Residual effect (1 week later)
Normal volunteers

10 Farhan (4th week)	Atebrin	−4			−1	
(*c*) With blackwater fever						
11 Atassi	Atebrin	−21	−5		+16	0

TABLE 2

	Deviation of I.F. response from normal S.C.F. curve I										
	Before	1st week	2nd week	3rd week	4th week	5th week	6th week	7th week	8th week	8th month	12th month
Normal volunteers (average of 50) Effect of vaccination with T.A.B.	0	+9	+5						+1	0	0
Typhoid cases—uninoculated											
(*a*) Severe infection		−1	−4	−10	−10	−4	−1	−1	0		
(*b*) Moderately severe case with relapse		−4	+5	−10	−10	−4	0				
Typhoid cases—inoculated		−1	+10	+32							

malarial infection (Case 1). This soon gives way to a negative response, which was more marked in Case 2 observed on the sixth day of illness and less so in Case 3 observed on the tenth day of illness. More marked initial inhibiting factor depletion was obtained in the two cases of relapsing malaria and most marked in *P. falciparum* infections with cerebral manifestations (Cases 6 and 7), and with blackwater fever (Case 11).

The course of the struggle between the malarial parasite and the host as well as the aid provided by quinine and atebrin seem to be mirrored by fluctuations in this inhibiting factor response. Thus a renewal of clinical activity in Case 2 was ushered in by a maximal negative inhibiting factor depletion, while a positive inhibiting factor response was associated with a remission. A similar finding was observed in a typhoid relapse (Table 2).

Furthermore, the extent of these fluctuations and the degree of residual stimulation seems to be of significance in determining the outcome of this struggle. Thus in two cases of relapsing malaria, Case 4 showed more fluctuations but no residual inhibiting factor stimulation, while Case 5 showed a steady increase in inhibiting factor with a maximal residual inhibiting factor response. The former patient continued relapsing for another eight months, while the latter showed no more relapses over a two-year period of follow up. In the two cases of *P. falciparum* infections with cerebral manifestations, it was found that Case 6 showed a complete absence of any inhibiting factor response despite 2 gm. of atebrin, while Case 7 showed a sluggish response. The former died while in the hospital, and the latter left the hospital as improved.

Of interest is the very sluggish inhibiting factor response obtained despite atebrin therapy in all *P. falciparum* infections. The only exception encountered was the case of blackwater fever, which showed a surprisingly good inhibiting factor response, even to the small dose of atebrin given.

Table 2 shows the positive inhibiting factor response obtained in fifty healthy volunteers as a result of immunization with T.A.B. vaccine. It also shows the negative inhibiting factor response which results from infection with *E. typhi*. In a severe case observed in a non-inoculated patient this negative inhibiting factor response appeared in the first week, reached maximal depletion in the third week and remained until the eighth week. In contrast to that the phase of negative inhibiting factor response was much shorter in the inoculated group, being over by the second week. This was in agreement with the clinical severity observed in the uninoculated as compared to the inoculated groups.

There is therefore evidence to indicate that this inhibiting factor present in the albumin residue of man, which is detectable in the serial cephalin flocculation curve and which is possibly elaborated by the liver, is in fact a *resistance factor*—of great importance in determining the course and outcome of this struggle between host and parasite. A decrease of this resistance factor shifts the balance in favour of the parasite, while an increase shifts the balance in favour of the host.

Such an increase in the resistance factor could be brought about by two different mechanisms :

(1) An immediate and non-specific increase as a result of the administration of *non-antigenic* substances as in the case of the two drugs used, quinine

and atebrin. This effect is maximal during the administration of the drug, when large doses are reached. There seems to be no residual and no delayed effects.

(2) A residual and a delayed increase brought about by the repeated administration of *antigenic* substances as in the case of T.A.B. vaccine or as occurs with repeated attacks of malaria and the resultant liberation of malarial proteins. This second mechanism seems to be more specific, but is distinct from the specific globulin antibody response which is also obtained in these cases. The residual effect obtained in the case of this resistance factor was maximal one week after the cessation of immunization, whereas the antibody response demonstrated by the zone of flocculation in the serial cephalin flocculation curve was maximal two weeks after the cessation of immunization.

The delayed effect comes into action whenever the immunized host is infected with the same agent.

A more detailed account is in the press.

I wish to thank Prof. E. W. Dennis, head of the Department of Bacteriology and Parasitology of the American University of Beirut, for his valuable advice.

INTERSTELLAR MATTER

THE George Darwin Lecture entitled "Some Phenomena connected with Interstellar Matter" was delivered by Prof. J. H. Oort before the Royal Astronomical Society on May 10, 1946, and the lecture has now been published in full (*Mon. Not. Roy. Astro. Soc.*, 106, 3; 1946). Prof. Oort deals more with a survey of the problems presented by interstellar matter than with an account of our present knowledge on the subject. The uneven distribution of interstellar matter is the first characteristic that strikes the investigator, and this applies to interstellar gas as well as to obscuring clouds. On the average, the light from a star 1,000 parsecs distant traverses five clouds, and it can now be accepted that the dark clouds contain proportionate concentration of gas. It has been shown that, on the average, the intensities of interstellar lines increase proportionally with the distances of the stars in all galactic longitudes, the only explanation of which is that these lines are mainly formed in clouds having 'peculiar' velocities averaging 15 to 20 km./sec. in the radial component.

The very uneven distribution of obscuring matter is noticeable even in the galactic plane, and two extended systems of dark clouds are found in our neighbourhood, one in the Taurus–Auriga–Perseus region, and the other in Ophiuchus and Scorpius. Both systems cover regions of about 500 square degrees and show an average absorption of mag. 0·8, although they are comparatively close to us—about 100–150 parsecs. In contrast to the strong absorption in these clouds, there are very faint Cepheids in Cygnus the apparent magnitudes of which are scarcely affected by absorption, although their distances are between 10,000 and 20,000 parsecs. As the average diameters of the interstellar clouds are of the order 100 parsecs and their peculiar velocities 20 km./sec., a cloud will encounter another in about 10^7 years, and some remarkable effects will result from such an encounter. Incidentally, it might be expected that the individual cloud systems and their relative motions would disappear in a time short in comparison with the age of the galactic system; but as this has not occurred there must be some mechanism causing reformation and motion. Independent data suggest that this is taking place, and the six-colour photometry carried out by Stebbins and Whitford, as well as other evidence, show that the dependence of interstellar scattering upon wave-length is the same for all stars, no variation occurring whether observations are made through dense clouds or through a thin medium. This implies that particles within dense clouds have the same radii as outside particles; and if it is assumed that these particles grow by condensation from the interstellar gas, the only interpretation is that the clouds are being continually reshuffled.

Two effects will result from an encounter between clouds. First of all, the intermediate region between the clouds will be compressed, and if the relative velocity of an encounter is 30 km./sec., the density and temperature in this region will be three times their value in the clouds. Hydrogen will be ionized by collisions and the gas will become luminous, the luminosity being most conspicuous when the interface between the clouds is in the line of sight from the earth. This may be the explanation of the bright rings often observed near the dark nebulæ when these are bordered by luminous nebulæ, and the luminescence of nebulæ like the extensive nebulosities near Zeta Orionis or the North American nebula may be caused by this collisional mechanism rather than by radiation from the stars.

Another effect is the evaporation of the solid particles of the two colliding clouds when the particles of one cloud hit other particles of comparable size. The probability of such evaporation cannot be ignored, and it may play an important part in the realm of interstellar material. This leads to the problem of the origin and growth of these solid interstellar particles, of which the radii are 1,000 A. A full discussion of this last and very important question would be impossible in the limited space, but briefly it can be said that an order of magnitude of 10^{-24} gm./c.c. for the density should preserve a balance between condensation and evaporation.

Among other astronomical problems in which interstellar material plays an important part reference may be made to the significance of interstellar material in the extragalactic nebulæ. There is no trace of it in the elliptic nebulæ; but it is very prominent in the spiral nebulæ, especially in the case of objects seen on edge. If the dark matter were comparable in mass with all the stars in a nebula, it might lead to instability, and spiral arms would be formed. The absence of such material in the elliptic nebulæ would offer a possible explanation of their stability; but it is admitted that such suggestions are still merely speculative.

The problem of the resistance of interstellar gas to the expanding shell thrown off by a nova is considered, and it is shown that in the case of an ordinary nova expanding in an interstellar medium of average density the deceleration should be observable within half a century. For supernovæ the deceleration would become visible only after several thousand years.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Assistant to teach Civil Engineering subjects, particularly Surveying and Structures to honours degree standard, Assistant Lecturers to teach in some selected branch of Civil or Mechanical Engineering up to degree standard, Assistant Lecturers to teach classes of a Workshop or Production Engineering character up to Higher National Certificate in Production Engineering and/or Motor Vehicle Service work for the National Craftsman's Certificate, and a Lecturer in Mathematics—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (August 16).

Lecturer in Metallurgy with Special Responsibility—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (August 16).

Lecturer (Grade I) in Organic Chemistry, a Lecturer (Grade IIa) in Chemistry, and Lecturers (2, one Grade I, one Grade IIc), mainly for research into the chemistry of high polymers and elastomers—The Secretary, The University, Edmund Street, Birmingham 3 (August 18).

Biochemist for research in endocrinological unit—Prof. Zuckerman, Anatomy Department, Medical School, Hospitals Centre, Birmingham 15 (August 18).

Physicist for research on applications of physics to medical problems, and an Assistant Physicist—The Secretary, Barnato Joel Laboratories, Middlesex Hospital, London, W.1 (August 23).

Zoologist for work in collaboration with the Water Pollution Research Laboratory at Watford on ecological and physiological problems connected with polluted waters—The Director, Freshwater Biological Association, Wray Castle, Ambleside, Westmorland (August 23).

Lecturer (Grade II) in Mechanical Engineering, and Assistant Lecturers (Grade III) in the Mechanical Engineering and Civil Engineering Departments—The Registrar, The University, Liverpool (August 23).

Senior Lecturer or Lecturer in the Department of Philosophy with special qualifications in Political Philosophy—The Registrar, The University, Manchester 13 (August 23).

Deputy City Analyst—The Town Clerk, City Council Chambers, 1 Clarence Parade, Southsea, Hants (August 30).

Laboratory Assistant at the Marine Biological Station, Millport—The Secretary, Scottish Marine Biological Association, 185 St. Vincent Street, Glasgow, C.2 (August 30).

Lecturer in Chemistry (Inorganic and Analytical Chemistry) in University College, Dundee—The Secretary, The University, St. Andrews (August 30).

Assistant Analyst—The City Analyst, 152 Great Charles Street, Birmingham 3 (August 30).

Senior Lecturer in Botany in the Rhodes University College, Grahamstown—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, London, W.C.2 (August 31).

Lecturer in Biochemistry—The Professor of Chemical Pathology, British Postgraduate Medical School, Ducane Road, London, W.12 (September 1).

Assistant (Lecturer) in the Department of Biology—The Secretary, Medical School, Middlesex Hospital, London, W.1 (September 1).

Readership in Economics (Banking and Currency) tenable at the London School of Economics—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 4).

Senior Experimental Officer or Experimental Officer (temporary), Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting A.261/47A (September 5).

Principal Scientific Officer or Senior Scientific Officer (temporary), Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting A.260/47A (September 5).

Senior Scientific Officer or Scientific Officer (temporary), Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting A.259/47A (September 5).

Principal Scientific Officer (temporary), Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting A.258/47A (September 5).

Deputy to the City Analyst—The Medical Officer of Health, Public Health Department, Leeds, endorsed 'Deputy City Analyst' (September 8).

Engineer Control Officers (temporary), Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting C.417/47A (September 13).

Lecturers (2) in Mathematics—The Secretary, King's College, Strand, London, W.C.2 (September 15).

Lecturer (ungraded) in Veterinary Parasitology, and a Lecturer (Grade II) in Marine Biology at the Port Erin Station—The Registrar, The University, Liverpool (September 15).

Professor of Chemistry in University College, Dundee—The Secretary, The University, St. Andrews (September 15).

Rector of Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 15).

Reader in Anthropology in the Department of Geography in the Newcastle Division of the University—The Registrar, University Office, 46 North Bailey, Durham (September 15).

Chair of Comparative Philology of Slavonic Languages tenable at the School of Slavonic and East European Studies—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 23).

Soil Chemist in the Department of Agriculture and Forests, Sudan Government Research Division—The Sudan Agent, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Soil Chemist' (September 30).

Chair of Town and Country Planning in the University of Sydney—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Sydney, September 30).

Economic Entomologist and an Entomologist for research (particularly on control) and general survey of all insect life of the country, and an Entomologist for work in the Plant Protection Division on general applied entomology and pest control (not research), to the Directorate-General of Agriculture, Government of Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.12711.

Head of the Building and Civil Engineering Department—The Acting Principal, Royal Technical College, Salford 5.

Senior Lecturer in Physics—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Assistant Research Chemists (2) in the Hop Research Department—The Registrar, Wye College, Wye, Ashford, Kent.

Lecturer in Physics—The Registrar, The University, Reading.

Lecturer in Electrical Engineering, a Lecturer in Mechanical Engineering, a Lecturer in Civil or Structural Engineering, a Lecturer in Production Engineering, and a Lecturer in Automobile Engineering, in the Chance Technical College—The Chief Education Officer, 215 High Street, Smethwick 41.

Qualified Physicist or Engineer with mathematical ability to join a research team investigating rolling mill problems—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Rolling Mill'.

Research Assistant in the field of Organic Chemistry—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

Laboratory Technicians (2, Grade B)—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

Research Assistants (2, one with medical qualification or degree in a biological subject, the other with honours degree in organic chemistry)—The Secretary, Department of Chemotherapy, School of Tropical Medicine, Pembroke Place, Liverpool 3.

Forester as Head of a Forestry Division for the Directorate General of Agriculture, Government of Iraq, The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18183.

Laboratory Technician (male)—The Secretary, Department of Parasitology, School of Tropical Medicine, Pembroke Place, Liverpool 3.

Assistant Lecturer in Physics—The Registrar, University College, Exeter.

Senior Lecturer or Lecturer in Philosophical Psychology, and an Assistant Lecturer in Experimental Psychology, in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2.

Hydrographical Surveyor (Grade III) by the Government of Iraq for the Basrah Port Directorate—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.17048.

Curatorship of the Zanzibar Peace Memorial Museum—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Lecturer in Electrical Engineering, Technical Institute, Lagos, Nigeria—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Hood Professor of Mining—The Secretary, The University, Edinburgh.

Director of Museums, Museums Department, Malaya, and a Curator of the Perak Museum, at Taiping—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Lecturer in Horticulture in relation to commercial glasshouse production—The Director, School of Agriculture, Sutton Bonington, Loughborough.

SOCIOLOGICAL SIGNIFICANCE OF LANGUAGE AND CULTURE

IT became very evident during the Second World War that England was unable to produce, at a time when their services were most urgently needed, sufficient experts in Slavonic, East European, Near Eastern, Far Eastern, and African languages to carry out essential military and political functions. Still fewer men could be found who combined a knowledge of these languages with an equal knowledge of the peoples who speak them and of their histories, social structures, and cultures. It has also become clear that, as a result of the War, British relations with these peoples will have to be based far more than hitherto on personal contacts, demanding sympathetic understanding of their ways of life and thought, and that an aloofness born of political and economic supremacy can no longer be afforded.

The realization that the study of Oriental, African, Slavonic, and East European languages, societies, and cultures is of national importance and, therefore, a concern of the State led to the appointment by Mr. Eden of an interdepartmental commission of inquiry, presided over by the Earl of Scarbrough, in December 1944. Its terms of reference were : "To examine the facilities offered by universities and other educational institutions in Great Britain for the study of Oriental, Slavonic, East European and African languages and culture, to consider what advantage is being taken of these facilities and to formulate recommendations for their improvement".

The Commission concludes from its inquiry* that the present provision for these studies is "unworthy of our country and people". Even this is an understatement. The state of linguistic and sociological research in the whole area within the Commission's terms of reference is deplorable. The facilities for teaching the required subjects in Britain were in 1939 well behind those in several European countries.

The chief reason for the public indifference which the Commission deplores is, as its report stresses, the absence of a sound academic tradition in the subjects under consideration. There have been here and there isolated professorships ; but there have lacked strong teaching departments in which a tradition could grow and be added to by one generation of scholars after another. It was not until 1916 that, to implement the findings of Lord Reay's Committee, the School of Oriental Studies was established in London, largely through the energetic backing of Lord Cromer and Lord Curzon. It took the stimulus of the First World War to bring about the establishment in 1918 of the School of Slavonic Studies, also in London. Credit for the foundation of the International African Institute in 1926, under the chairmanship of Lord Lugard, must be given to private initiative and American generosity.

The report of the Scarbrough Commission, therefore, lays it down that there can be no public enlightenment about the Far and Near East, Eastern

---

* Foreign Office. Report of the Interdepartmental Commission of Enquiry on Oriental, Slavonic, East European and African Studies. Pp. 192. (London : H.M. Stationery Office, 1947.) 3s. net.

Europe, and Africa until an academic tradition has been created in university departments dealing with the languages and cultures of these areas. It goes on to point out that no such tradition can be created, especially to-day when there is no longer a leisured class in Great Britain, and the Diplomatic, Consular, and Colonial Services are no longer leisurely occupations, unless students can be assured professional status and financial security. For a man without private means to take up as his life's work a study regarded by most people, including his relatives and friends, as a hobby of well-to-do eccentrics, he must have adequate funds to maintain himself during his training and research and until he has had time to publish enough of the results of his research to qualify for a teaching post. He must also have reason to believe that if he does qualify for a teaching post by the excellence of his work, there is a possibility of there being a place for him in some university department; for the genuine scholar is seldom willing to be absorbed into some other occupation for which his specialized knowledge may seem to qualify him. Neither of these pre-requisites to an academic career in the subjects under discussion have existed in the past. If the Commission's recommendations are accepted by the Government, however, they will exist in the future.

The report, which is comprehensive and admirably to the point, asks first for the strengthening of university teaching departments and the creation in certain cases of new departments in universities other than Oxford, Cambridge, and London; secondly, for a generous allotment of post-graduate studentships; and thirdly, for the establishment of research centres abroad in close liaison with British universities. These are minimum requirements involving very moderate expenditure spread over a number of years. In return for its aid, the State will receive training facilities for careers in the various countries covered by the report, and, eventually, a better informed public opinion about these areas, which are inhabited by nearly five-sevenths of the population of the world.

If the State is to receive this return, the universities must ensure, says the report with very good sense, that there is a fair balance between classical and modern studies and between linguistic and cultural studies. The tendency in the past, perhaps particularly in Semitic studies, has been to concentrate far too much on the classical literature to the neglect of the language spoken and written to-day. There has also been undue emphasis on purely linguistic teaching. A language can, of course, be learnt without the learner knowing much about the history, culture, or social life of the people who speak it; but it certainly cannot be understood without a sound knowledge of them, and there is no more fallacious guide than the man who speaks a people's language but has not studied their institutions and values. The absence of sociological research in the Near and Far East is astounding. It would not be going too far to say, for example, that no comprehensive and intensive sociological study has yet been made of any community in the Near East or India.

This lack of sociological research may be in part a shortcoming of the social anthropologists who have stuck too closely in their studies to primitive peoples, though for the good reasons that these primitive peoples are fast disappearing and the number of social anthropologists has always been very small indeed. But it is also a fault of the orientalists, whose interests have generally been too purely linguistic, sometimes too purely philological. What is required is closer co-operation between oriental studies and social anthropology, such as has existed in the African field between linguistic and anthropological studies. There are hopeful signs of this development.

It may be expected that the universities will play their part by taking a keener interest in the contemporary world. This does not mean that they will give foremost attention to practical aims in their teaching and research. It is much to be hoped that the Government will allow them an entirely free hand to give broad scholarly teaching and to conduct fundamental research in their own way. Nothing deadens teaching and inhibits research more than direction by a committee of people whose interests are in immediate practical benefits and results. If the aims of the Scarbrough Commission's report are to be achieved, it is essential that whatever committee administers the studentships the creation of which is recommended should choose the men but not the plans of research. It should not draw up a list of projects and try to find men to fit them, but should let each man, chosen on general grounds for his ability and interests, select his own field of inquiry and his own problems within that field without regard to immediate dividends.

Indeed, the Government should look on any expense it may incur in implementing this report not as charity but as a sound investment likely to pay a handsome dividend in goodwill from the peoples of the Far and Near East, Eastern Europe, and Africa, and in the commercial and political benefits which goodwill brings in its train. Nothing endears one people to another more than awareness that its history, language, and culture are a sincere and respectful concern of the other.

RADIO TRANSMISSION LINES AND WAVE GUIDES

Electrical Transmissions in Steady State

By Paul J. Selgin. (Radio Communication Series.) Pp. ix+427. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 25*s*.

The Physical Principles of Wave Guide Transmission and Antenna Systems

By Prof. W. H. Watson. (International Monographs on Radio.) Pp. xiv+208. (Oxford: Clarendon Press; London: Oxford University Press, 1947.) 20*s*. net.

THE problem associated with the applications of radio waves to communication, location or navigation is to generate high-frequency alternating currents and convey them from the source to an antenna system which radiates the waves into space. The connecting link between the source and the radiator is termed a transmission line, and for moderately high radio frequencies may comprise a system of two parallel wires, or a coaxial cable or some elaboration of these. At the very high frequencies corresponding to wave-lengths less than a few centimetres in length, this transmission line system takes the form of hollow conductor of circular or rectangular cross-section termed a wave guide. The two books under review deal respectively with transmission lines and wave guides as used in modern radio frequency technique.

Mr. Selgin's intention in the first book is revealed by his definition of a hypothesis of steady state according to which "it is assumed that the amounts of energy transmitted through any junction over two successive equal time intervals, at any particular frequency, are not appreciably different, provided that the period of this frequency is small compared with the intervals considered". It is then pointed out that, though strictly speaking all communication signals must be regarded as transients, it is permissible to adopt this loose definition as a guiding principle for practical purposes.

Nearly half the book is devoted to transmission lines with eight of the seventeen chapters treating uniform non-reflecting lines, distortion, terminal reflexion, power flow, long lines, matching devices, composite lines and stubs and exponential lines. Having this material collected together and coordinated in a single volume is perhaps the most valuable feature of the book, for the treatment is thorough and competent, and this ground is not fully covered in any other single treatise. Emphasis is laid on design problems and on their mathematical solution, particularly with the aid of vector and circle diagrams. The analytical methods required are adequately introduced for a student coming fresh to the subject.

The longest chapter (No. 10, 54 pp.) is that on "Composite Lines and Stubs", which is mainly concerned with the multisection (line) transformer and its optimum design for wide-band transmission and with the selectivity and efficiency of stub tuners. Among the illustrative examples, the effect of the capacity of regularly spaced dielectric insulators in a coaxial cable is considered.

The second longest chapter (No. 14, 40 pp.) gives a full treatment of "Inductive Coupling and Transformers"; and intervalve-coupled tuned circuits are analysed in detail with advantageous use of the parabolic locus method of presenting the results.

Chapters 11 and 12 introduce electromagnetic theory in a manner well suited to the purpose of giving a deeper understanding of circuit and line theory. The clarity and conciseness of these chapters is particularly praiseworthy, as is the refreshing appeal to physical fundamentals which is rare in books intended for engineers.

An attempt is made in the last two chapters to treat valve amplifiers within the general framework of transmission through linear networks, and the gains of the grounded-cathode, grounded-grid and grounded-anode (or cathode follower) amplifiers are deduced. The treatment is rather unsatisfactory and gives the impression of attempting too much in too short a space; the unorthodox graphical symbols and the elaborate vector diagrams also tend to obscure the relatively simple nature of the analysis involved. The book is well printed and only a few errors have been noted. The bibliography is, however, disappointing, for it refers to forty books but only two original papers (both more than twenty years old), and these are not likely to be helpful as many of them are either obsolete or inaccessible to students in Great Britain. Within its scope, which intentionally excludes radiation and wave guides, the book can be recommended to the engineer who is concerned with the design of circuits and transmission lines up to moderately high frequencies, and its treatment is modern and practical without neglect of essential fundamental principles.

Prof. Watson's book is one of a new series of International Monographs on Radio, and is intended to present a description of the manner in which the technique of dealing with radio frequency transmission lines has been extended to propagation through wave guides. When the cross-sectional dimensions of a wave guide are chosen correctly in relation to the wave-length, only one characteristic mode of propagation, the so-called 'dominant wave', is effective in transmitting energy along the guide. The first five chapters of the book give a detailed theoretical treatment of the underlying physical principles of this type of radio wave propagation along wave guides. With the aid of the impedance concept the usual circuit analysis is applicable in many respects to waves along transmission lines as to waves in free space. The problem of wave propagation along a hollow rectangular guide is attacked by an investigation of a system of two interfering trains of plane waves. Chapter 3 contains a useful although brief description of the basic measuring techniques which are essential for any experimental work on wave guides, and includes reference to standing wave detectors, power and phase measurement, and the radiation pattern and gain of antenna systems. The general problem of multiple propagation of waves along guides of either circular or rectangular cross-section is dealt with in the following chapter; it is here that the two characteristic distributions in a wave guide are described. In one of these, termed *TE*, the waves are propagated in such a manner that the electric force is transverse only, while in the other case, of the *TM* waves, the magnetic force is confined to the transverse direction. By an application and extension of Babinet's principle, it is shown in the succeeding chapters how wave guides can be coupled together by means of suitable slots in their sides, and how such slots may also be used to obtain radiation from a wave guide into free space. This portion of the book presents the results of much of the author's original work in recent years in the study and development of slot radiators and antenna systems for centimetre wave transmission and reception. Chapters 8 and 9 discuss in some detail the principles and characteristics of various types of wave-guide arrays and slot aerials, many forms of which have been developed for special applications of radar technique.

In this book, which is well produced and illustrated, Prof. Watson has presented very clearly the results of much original work in elucidating the physical principles of wave guide transmission, the technique of which is likely to play an important part in the applications of very short radio waves in the future. Much of the work in the book is made generally available for the first time, and most of the references given at the end of the book are to papers and reports which have hitherto been classified as confidential. With the rapid publication now taking place in scientific and technical journals in Great Britain and in America, the author should be able to improve this bibliography in a later edition: the opportunity might then also be taken of adding a subject index to the name index which is given at the end of the present book, although the detailed nature of the contents virtually forms a subject index.

R. L. SMITH-ROSE

MODERN CARBOHYDRATE CHEMISTRY

Advances in Carbohydrate Chemistry
Edited by W. W. Pigman and M. L. Wolfrom (Associate Editor for the British Isles: Stanley Peat.) Vol. 2. Pp. xiv+323. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1946.) 6.60 dollars.

THIS volume by no means suffers in comparison with the first in this series (see *Nature* **157**, 676; 1946), and represents a valuable collection of articles setting out the state of knowledge of the subjects selected up to about the end of 1945, the number of references dated 1946 amounting only to six. The choice of subjects is suitably wide, and the articles on anhydro sugars, the analogues of ascorbic acid, the chemistry of mucopolysaccharides and mucoproteins, bacterial polysaccharides and the chemistry of pectic materials are outstandingly good.

In common with the reviewer of Volume 1, I think it is unfortunate that in a publication of this kind detailed experimental work should be included, for great difficulties are likely to arise, especially for abstractors, if the practice is extended. Although none of the British authors is an offender in this respect, the fact that a member of the editorial board has included experimental details in both volumes gives rise to misgivings for the future.

The first thirty-six pages are devoted to an exhaustive memoir by C. S. Hudson on melezitose and turanose. The history of the chemical investigations is described in great detail, and the evidence proving that turanose is 3-α-*d*-glucopyranosyl-*d*-fructose is presented. That experimental evidence is lacking as to whether melezitose contains a sucrose residue is made clear, although many workers will be surprised if this is not the case. The present description of melezitose must, therefore, be 3-[α-*d*-glucopyranosyl]-(?)-*d*-fructofuranosyl-α-*d*-glucopyranoside.

The account by Stanley Peat of the chemistry of the anhydro sugars is noteworthy, and represents a complete survey of this important and fascinating topic. Not only is this article invaluable for reference purposes, but high praise is due for the logical treatment and clarity of style in discussing a complex subject which the author himself has done much to develop.

In the section on ascorbic acid analogues, Fred Smith summarizes the methods of synthesis and properties of these substances, and the hitherto puzzling behaviour of the saccharodilactones is explained by their conversion to reducing enolic forms.

The account by R. Lespieau of the synthesis of hexitols and pentitols from unsaturated polyhydric alcohols is decidedly stimulating to those carbohydrate chemists who, like the reviewer, tend to neglect the possibilities of synthesis on account of the vast field of natural products awaiting investigation.

Harry J. Deuel, Jun., and Margaret G. Moorhouse discuss the interrelation of carbohydrate and fat metabolism in an article covering forty-one pages in which nearly two hundred and fifty references are quoted. This article fulfils one of the objects set forth in the Editors' preface to Volume 1, namely, "It may be found desirable to present several reviews of controversial subjects, particularly in those fields undergoing a rapid state of development".

The extraordinary complexities of the mucopolysaccharides and mucoproteins are discussed by Maurice Stacey in a stimulating contribution which should do much to encourage workers to embark upon researches on these substances. The unusual step of introducing exclamation marks into a scientific article presumably indicates the author's impatience with earlier work in this field; it must be remembered, however, that we stand upon the shoulders of the previous generation even if the foothold seems precarious at times.

Taylor H. Evans and the late Harold Hibbert are responsible for an excellent report on bacterial polysaccharides. I was working with Hibbert in Montreal when some of the investigations described were in progress, and it is a great pleasure to see the results collected together, and to recall the enthusiasm of one whose scientific achievements were not, perhaps, sufficiently appreciated in his life-time.

E. L. Hirst and J. K. N. Jones contribute an account of the chemistry of pectic materials which might well serve as a model for future articles; for the temptation to expand by the full discussion of outmoded earlier results is rejected, to the great profit of the reader.

The polyfructosans and difructose anhydrides are described by Emma J. McDonald in a useful survey of a subject the study of which is beset by many experimental difficulties, and a short survey of cellulose ethers of industrial importance by Joseph F. Haskins reminds the reader of the advances made in a more strictly utilitarian field.

Few mistakes were found in this attractive and useful book, and these principally in the initials of the authors in the references. The practice of printing the Christian name in full for women authors, which indeed is highly commendable, has resulted in an apparent sex reversal (references 30, 65, 103, in the article on bacterial polysaccharides), as those will observe who studied public health chemistry under Dr. E. Ashley Cooper at Birmingham.

E. G. V. PERCIVAL

X-RAY ANALYSIS AS A TOOL IN CHEMISTRY AND TECHNOLOGY

Röntgenographisch-analytische Chemie
Möglichkeiten und Ergebnisse von Untersuchungen mit Röntgeninterferenzen in der Chemie. Von Prof. Dr. E. Brandenberger. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften, 7.) Pp. 287. (Basel: Verlag Birkhäuser, 1945.) 28.50 Swiss francs.

IN Great Britain, X-ray crystallographers are abundant, and each can afford to specialize. Some of us take to hydrocarbons, others only to carbohydrates, and to others again only the fibrous state of matter appeals. In Switzerland, crystallographers are scarce, and a man who wants to serve university and industrial laboratories alike must be able to master not only all the techniques of X-ray analysis, but also electron diffraction and radiography as well. Prof. E. Brandenberger at Zurich directs such an all-round X-ray laboratory, and in the book under notice he tries to explain to his colleagues the potentialities and limitations of X-ray diffraction.

The title suggests a narrower field than is actually covered, for the book ranges beyond the applications of X-ray analysis to chemistry. As the author explains in the introduction, he does not aim at adding one more to the many text-books on the principles and methods of X-ray analysis—personally I have never found that there was such an abundance—but to review the variety of problems that can be investigated and to illustrate the kind of information that X-ray analysis can provide in each particular case. For all explanations of fundamental principles the author refers to other literature (not even Bragg's law is derived), and only a brief section at the end of the book is devoted to actual crystal structure analysis, including an exposition of some of the more elementary laws of crystal chemistry.

The first part of the book deals with the identification of crystalline phases; this involves the author in the difficulties of defining the term 'crystalline' and leads him to an elaborate classification of lattice types intermediate between the crystalline and the amorphous state. The other sections deal with the analysis of mixtures and multiphase systems, with the study of crystal texture and with reactions in solids. In each chapter the uses of X-ray analysis are rigorously classified and sub-classified, detailed instructions about the preparations of specimens are given, and lists are drawn up of all the different phenomena that might occur and of their interpretation. Some readers may find the absence of any connecting links between the observations and the conclusions to be drawn from them a little disconcerting. It has to be accepted as a statement of fact, say, that lattice distortion causes asterism on Laue pictures or that line-width is an inverse function of crystal size, and no explanation, even qualitative, is offered to the curious about the mechanism involved. Incidentally, workers in Great Britain will probably consider the author to be over-optimistic when he asserts that both the average size of the crystallites and the degree of lattice distortion can be determined from one powder photograph by plotting successively $b \cos \theta$ and $b \tan \theta$ against θ.

There are long lists of references at the end of each chapter; some of those referring to German papers which appeared during the War may be new to readers in Britain. Unfortunately, no author index is provided.

To the university student and to the reader who seeks to understand physical phenomena the book has little to offer; but workers wishing to apply more powerful techniques to the examination of materials and processes might find parts of it useful and interesting, though not very easy to read. Personally, I am inclined to think that the potentialities of X-ray analysis can be judged more easily from a knowledge and understanding of the fundamental physical principles than from a survey of its applications, however painstakingly compiled.

M. F. PERUTZ

LIVESTOCK IMPROVEMENT IN U.S.S.R.

Stockbreeding and the Artificial Insemination of Livestock

By V. K. Milovanov and I. I. Sokolovskaya. Translated by Dr. A. G. Morton. Pp. 160. (London: Hutchinson's Scientific and Technical Publications, 1947.) 25*s*. net.

THIS book presents the Russian point of view on the scientific and practical methods which can be used for the improvement of livestock. Mention of some of their principal local breeds and a tribute to early English breeders is contained in the introduction. Darwin's theories on the causes for variation and on natural selection form the main theme throughout the first two chapters. Correlated variations are illustrated by examples from Russian experimental work which shows the relative proportions of different parts and tissues of the body in different types of sheep (milk, meat and wool) and of cattle (meat, milk and draught). The importance of the creation of suitable environmental conditions in which to make selection of breeding animals is stressed. Many ideas novel to the British breeder are propounded, for example, that nervous activity is associated with body conformation. Pavlov's finding that the 'over fine' animal has weakness in both stimulatory and inhibitory processes is quoted in support of this.

In a chapter on selective breeding 'compensatory matings', that is, mating an animal which has a certain defect with another which is particularly good in this respect, are criticized, while a system of 'homogeneous matings' (like to like) is approved. Breeding methods, such as inbreeding, line-breeding and economic cross-breeding, are discussed, often with reference to English examples.

Perhaps the most interesting chapter in the book is that on the artificial insemination of livestock; the Russian method of insemination by semen-filled paper capsules is described and illustrated. Many of the statements made in this chapter could, with advantage, be backed by full experimental details to support them, since in some respects at any rate they differ from the views usually accepted. For example, it is stated that superabundance as well as insufficiency of spermatozoa has an adverse effect on fertilization. Details are given, however, of selective fertilization of rabbit ova by the inseminated sperm of two different varieties. Methods for testing the quality of the semen are described; but no mention is made of recent methods of insemination developed in the United States and in Great Britain.

A chapter on the maintenance, feeding and utilization of breeding animals contains much useful information on the effects of different feeding-stuffs on semen production, on methods of testing male and female animals for fertility, and on the conditioned reflexes associated with service. The lack of understanding of these latter is a frequent cause of bulls failing to function properly at artificial insemination centres.

In the concluding chapters the development of the young animal is outlined with special reference to the effect of nurture on its development, while observations are also included on the formation of new breeds and the improvement of old ones.

British breeders will find in the book a number of the old, but perhaps now not too widely read, ideas of Darwin on the selection and evolution of animals under domestication, interspersed with many new points of view and observations on reproduction and livestock breeding. JOHN HAMMOND

AN INTRODUCTION TO MODERN PHYSICS

From Galileo to the Nuclear Age

An Introduction to Physics. By Prof. Harvey Brace Lemon. Revised edition of "From Galileo to Cosmic Rays". Pp. xviii+451. (Chicago: University of Chicago Press; London: Cambridge University Press, 1946.) 21*s.* net.

ANY book that aims at presenting a readable account of modern science is to be welcomed, and Dr. Lemon's work on the development of physics from Galileo to the present time has this objective specially in view: Such a study, he claims, should have "something of that human interest that attaches to great personalities, but most of all it should try to show explicitly and implicitly how a great scientific field of thought has come into being. Moreover it should indicate the satisfaction enjoyed by those who participate in such a development of thought, as well as its practical advantages to mankind." Even a cursory glance at this volume shows how far the author has departed from conventional academic form, in order to interest his readers. His colloquial and homely style, together with many well-produced illustrations (sometimes stereophotographs) of a topical and frequently unconventional type, are designed to meet the needs of first-year university students in other faculties who have little background knowledge of the physical sciences. Though based on the curriculum of the University of Chicago, Prof. Lemon's treatment will undoubtedly appeal to similar students elsewhere, and, indeed, to the general reader.

The book is divided into five parts, dealing respectively with mechanics, heat, electricity and magnetism, electricity and matter, waves and radiation. Attention is directed to the underlying importance of the work of Galileo and Newton, and the first part includes successive chapters on work, energy, conservation of energy, power, and concludes with a convincing treatment of the problems of atmosphere and hydrosphere. Prof. Lemon has added to the general interest of his subject by including references to the origin of the Fahrenheit scale, the measurement of temperature by electrical means, and so on: the section on heat ends with a chapter on kinetic theory. Part 3, "Electricity and Magnetism", contains the ground-work study necessary for the appreciation of modern developments. In particular, a helpful approach to 'lines of force' is made by consideration of a gravitational field. In the last two parts of the book, the reader is introduced to an interesting survey of the conduction of electricity through gases, photo-electric and thermionic effects, electrons, radioactivity, electromagnetic waves, and atomic structure. In the part especially dealing with waves, a chapter on sound is inserted.

Though "From Galileo to the Nuclear Age" is primarily a survey of the modern achievements of physics and their dependence on the work of pioneers, the author does not ignore the implications and possibilities of science at this time. "Will man be able in the future so to conduct his political, social, and economic life as to put an end to war and prevent for the future the much greater powers of destruction that soon *all nations* will possess? *Unless this can be accomplished the darkest of all ages surely lies ahead; the rare joy that in the past has gone with the acquisition of knowledge will be known no more.* ... Let us devoutly hope that in some way these problems may be met in time so that future generations again can get some joy from probing still more deeply into the heart of Nature." H. D. ANTHONY

DISSECTION OF THE CAT

Functional Anatomy of the Mammal

A Guide to the Dissection of the Cat and an Introduction to the Structural and Functional Relationship between the Cat and Man. By Asst. Prof. W. James Leach. (McGraw-Hill Publications in the Zoological Sciences.) Pp. viii+231. (New York and London: McGraw-Hill Book Co. Inc., 1946.) 12*s.* 6*d.*

THE choice of a mammalian type suitable for dissection as an introduction to human anatomy and physiology has usually fallen on the rabbit or the rat. The rodent, however, is in many ways less suitable than the carnivore, which is less primitive and is structurally a little nearer to man. We welcome, therefore, this book on the cat as an elementary account of a common and easily obtained mammal.

Constant comparisons with human anatomy and physiology are stressed throughout, and there are many useful summaries. The effects of posture on modifications of structure, especially as regards the upright habit in man, are referred to in an interesting way that makes the book read well, and relieves it from the tedium of names and descriptions so characteristic of the average text-book. At the end of many of the chapters, problems relating to physiology, mechanics of joints and muscles, and surgery are suggested as a stimulus to the future nurse or medical man.

The systems of the body are dealt with in turn, using the injected cat for dissection. Has the author, however, used the just-born kitten instead of the adult cat? For many of the organs it proves much easier, although so much smaller. This is particularly the case with regard to the sympathetic nervous system, which can be demonstrated with ease owing to the relatively large size of the ganglia and the gelatinous nature of the connective tissue. The difference between the fœtal and adult circulations can also be elucidated.

The original line block illustrations are excellent, especially those relating to the skeleton and muscles. The labelling in full is also good. But the half-tone reproductions of drawings by John Trainor do not mix well with the others, and illustrations from other authors have not always been correlated with the text, so that the junior student for whom the book is intended will sometimes find it difficult to recognize the parts under their Latin names. The author's Latin is irregular; foramen ovale changes in the course of the book to foramen ovalis, while fossa ovalis becomes fossa ovale; the plural of plexus is wrongly given as plexi. These are small points that could be corrected in a later edition.

As with all McGraw-Hill publications the book is well produced and the price is reasonable.

N. B. EALES

RESEARCH IN GERMANY ON THE TECHNICAL APPLICATION OF ATOMIC ENERGY*

By PROF. W. HEISENBERG
Max Planck Institute of Physics, Göttingen

EVEN ten years ago, physicists were well aware that the utilization of atomic energy could not be realized without a fundamental extension of scientific knowledge. In spite of the remarkable progress in experimental nuclear physics which followed the introduction of high-voltage equipment and the invention of the cyclotron, no physical phenomenon was known, even as late as 1937, which offered the remotest possibility of exploiting the enormous quantities of energy lying latent in atomic nuclei.

It was the discovery of the fission of uranium by Hahn and Strassmann[1] in December 1938—in other words, the fact that the uranium nucleus can be split into two fragments of comparable mass when bombarded by neutrons—which brought the actual utilization of atomic energy within reach. Following this discovery, Joliot and his co-workers[2] succeeded in proving, in the spring of 1939, that in the act of fission the uranium nucleus itself emits several neutrons, thus making a chain reaction fundamentally possible. Thereafter the possibility of nuclear chain reactions was eagerly debated among physicists, particularly in the United States; in Germany it was discussed by Flügge[3] in *Die Naturwissenschaften* in the summer of 1939. Meitner and Frisch[4] had already directed attention to the enormous quantities of energy set free in the fission process.

Public interest in the problems of atomic physics was negligibly small in Germany between the years 1933 and 1939, in comparison with that shown in other countries, notably the United States, Britain and France. Thus, while in America, previous to 1939, a whole series of modern research laboratories equipped with high-voltage plants and cyclotrons was springing up, in Germany there were only two adequately equipped laboratories; and these were not supported by the State, but sponsored by a private body, the Kaiser Wilhelm Gesellschaft. These two institutes were the Kaiser Wilhelm Institutes at Heidelberg and Berlin-Dahlem; each possessed a small high-voltage set suitable for nuclear research. A cyclotron for such work was altogether lacking—the Heidelberg cyclotron, again built entirely by private funds, and mainly designed for medical investigations, was started as late as 1938, and could not be tested out before 1944. Only with the outbreak of war did the awakened interest of the authorities allow of more extended facilities for nuclear research.

The following report deals with those particular investigations which had for their purpose the technical utilization of atomic energy. The many purely scientific problems which arose in more or less close connexion with the technical problem will not be discussed here; they will be dealt with in a forthcoming FIAT* Review by Flügge and Bothe. I may, however, mention the extensive chemical investigations of Hahn and his co-workers on the fission products of uranium, carried out throughout the War in the Kaiser Wilhelm Institute for Chemistry, the great majority of which have been published.

Almost simultaneously with the outbreak of war, news reached Germany that funds were being allocated by the American military authorities for research on atomic energy†. In view of the possibility that England and the United States might undertake the development of atomic weapons, the Heereswaffenamt created a special research group, under Schumann, whose task it was to examine the possibilities of the technical exploitation of atomic energy. As early as September 1939 a number of nuclear physicists and experts in related fields were assigned to this problem, under the administrative responsibility of Diebner. I should mention the names of Bothe, Clusius, Döpel, Geiger, Hahn, Harteck, Joos and v. Weizsäcker among those so employed. At Schumann's behest, the Kaiser Wilhelm Institut für Physik in Berlin-Dahlem was nominated as the scientific centre of the new research project. The Institute came accordingly under the administration of the Heereswaffenamt; a step which disregarded the rights of the Kaiser Wilhelm Gesellschaft, and so led to the departure of its director, Debye, who as a Dutch citizen could not continue to serve under the ægis of a German war department.

As a result of the first conferences in the autumn of 1939, it was clear that there were two lines of attack possible in the exploitation of nuclear energy. One could attempt the separation of the rare isotope U(235) from ordinary uranium. This isotope, following theoretical arguments due to Bohr, must be immediately applicable either to the controlled production of energy, using primarily the slow-neutron reaction, or directly as an explosive in bombs, using the fast-neutron reaction; the separation of U(235) was, however, a problem which made the greatest possible demands on engineering technique. Secondly, one could mix ordinary uranium with a substance which would slow down the neutrons produced in the nuclear fission without absorbing them. These slow neutrons give rise preferentially to the fission of U(235) and thus maintain the chain reaction. A rapid deceleration of the neutrons is required, in order that the region of resonance absorption by U(238) should be rapidly traversed; for if absorbed they are lost to the chain reaction. The advantage of this arrangement is that the chain reaction can be controlled through the heat developed thereby, so that energy can be abstracted in amounts sufficient for technical applications.

---

* This article is a slightly abridged translation of a paper appearing in *Die Naturwissenschaften*.

* FIAT Reviews of German Science, 1939–1946: a series of authoritative accounts of the progress made in both natural and applied science in Germany during the War. These reviews have been sponsored jointly by British, American and French FIAT (Field Intelligence Agency (Technical)), and a limited edition is expected to be ready for distribution before the end of 1947.

† Cf. Smyth Report, p. 27: Initial approaches to the Government. In actual fact, U.S. Government funds were first used at the turn of the year 1939–40 (p. 28), whereas the first discussions between men of science and the American navy took place as early as March 1939.

Thus two lines of purely scientific investigation were marked out: first, to develop refined methods for the separation of isotopes; secondly, by measurement of the effective cross-sections of a range of possible substances, to determine whether the alternative line of attack was at all practicable. Harteck pointed out, as early as the autumn of 1939, that it might be advantageous, in regard to the second scheme, to have the so-called moderator physically segregated from the uranium. This suggestion gave rise to theoretical investigations as to whether, with the effective cross-sections of such moderator substances as were known at the time, an arrangement having a homogeneous mixture of uranium and moderator, or one with a local separation (for example, in layers), led to the more favourable production of energy. A tentative theoretical investigation made by Heisenberg, in December 1939, led to the result that while ordinary water was unsuitable as a moderator, it should be possible with heavy water (D_2O) or very pure carbon to produce energy in positive amount, provided the moderator and uranium were arranged in layers. This arrangement, however, demanded the highest degree of purity of the substances involved. At the same time, it was evident that a certain minimum size of apparatus was necessary for the production of energy. Nevertheless, with a small set it is still possible to determine whether there would be a production of energy if the apparatus were suitably enlarged. Thus if we feed such a small plant with neutrons from an internal source, more neutrons must escape from the surface than are supplied by the source, if the layer arrangement is favourable to energy production; if unfavourable, then fewer neutrons escape than are supplied by the source. These small model plants, which are continuously fed from a neutron source, are called 'neutron-injected piles'. The ratio k of the number of neutrons escaping from the pile to that fed in by the source can be used to characterize the pile. If $k \ll 1$, the arrangement is unsuitable for the production of energy; if $k > 1$, energy will be produced on enlarging the pile.

In 1940, measurements of the most important effective cross-sections were carried out, especially by Bothe and his collaborators, and by Döpel and Heisenberg. At the same time, investigations on the masses and energies of the fission products were being pursued by Jentschke and Prankl[5] and by Flammersfeld, P. Jensen and Gentner[6], and on the spectrum of the neutrons produced by Kirchner and v. Droste and by Bothe and Gentner[7]. The theory of neutron absorption in the U(238) resonance line was laid down by Flügge and Heisenberg. On the technical side the following results were the most important: the absorption cross-section of heavy water proved to be so low that this substance was certainly usable in the construction of a uranium pile (Döpel and Heisenberg). The work of v. Droste on large quantities of sodium uranate, and of Harteck and the Hamburg group—Groth, H. Jensen, Knauer and Süss—on U_3O_8 in solid carbon dioxide, furnished the first criteria for the distribution of neutron density in certain arrangements of uranium and moderator. In the autumn of 1940, the first pile, constructed of layers of U_3O_8 and light paraffin, was built at Berlin-Dahlem and its characteristics measured (Wirtz, Fischer, Bopp). This model pile gave, as expected, $k < 1$, that is, the arrangement was not suitable for the production of energy. Nevertheless, it yielded valuable data for further piles using alternate layers of U_3O_8 and heavy water.

In the summer of 1940, v. Weizsäcker pointed out that a uranium pile, besides generating the fission products of uranium, will constantly produce the uranium isotope U(239) and its transformation series; and that theoretically these transformation products should show the same properties as U(235) in regard to neutron fission. It remained thereby an open question whether β-decay ended at element No. 93 or 94 or even later; for, since no cyclotron was available in Germany, these elements could not be prepared in sufficient quantity for the examination either of their nuclear properties or chemical characteristics. Nevertheless, it appeared likely, from v. Weizsäcker's work, that an energy-producing pile might be used for the production of an atomic explosive, even though the practical details involved remained uncertain. In fact, this method had been employed on the grand scale in America. The American piles deliver as a transformation product of U(239) the element plutonium $^{293}_{94}$Pu, which is used in the manufacture of atomic bombs.

Important technical problems immediately arose out of these scientific investigations. The production of U_3O_8 of the highest purity was assigned to the Auer-Gesellschaft by the Heereswaffenamt. The casting of the corresponding metal powder was afterwards allotted to Degussa in Frankfurt. The production of heavy water, which was obviously of the greatest importance for the construction of a uranium pile, was planned at the Norsk Hydro factory at Rjukan in Norway. Harteck, in conjunction with Süss, H. Jensen and Wirtz, developed a number of projects which resulted in an increase of heavy water production at Rjukan far beyond the former output of 10–20 litres a month. Moreover, Harteck and Clusius put forward detailed plans for the production of heavy water in Germany. The improvements in the Norsk Hydro factory finally increased production in the summer of 1942 to about 200 litres per month. Further, steps were taken by order of the Heereswaffenamt for the production of very pure carbon. The attempts to exceed the degree of purity afforded by the best technical electrographite failed, however, for the time being.

The most important progress in the uranium project was achieved during the year 1941. Initially some negative results were recorded. Thus, the enrichment of U(235) by the Clausius–Dickel thermal diffusion method, using gaseous UF_6, proved impossible (Fleischmann, Harteck and Groth). The absorption cross-section for neutrons of the highest purity electrographite was determined in the Kaiser Wilhelm Institute at Heidelberg (Bothe and Jensen[4]), and the behaviour of pure carbon estimated from the results. It appeared, according to the information then available, that even the purest possible carbon was unsuitable for the construction of a uranium pile; whereas, as is well known, carbon has been used in the United States with complete success. Whether the Heidelberg conclusions were falsified by insufficient consideration of the chemical impurities present in commercial graphite (for example, hydrogen or nitrogen), or by deficiencies in the theory, can scarcely be assessed for the moment. In any event, the Heidelberg experiments on graphite and beryllium (Fünfer and Bothe[5]) made it clear, in connexion with later experiments in the Berlin–Dahlem Institute, that both pure carbon and pure beryllium were highly suitable for use as an outer cover for a uranium pile, inasmuch as their low absorption cross-section and high reflecting power restrict the spread of the neutrons escaping from the pile, thus reducing its minimum dimensions.

In the summer of 1941, 150 litres of heavy water were available for the first experiments on a neutron-injected pile built up of uranium and heavy water (Döpel and Heisenberg, Leipzig). The uranium and heavy water were arranged in alternate spherical layers with the neutron source at the centre. The oxide U_3O_8 which was first employed produced only a slight increase in the number of escaping neutrons, which could scarcely be considered a clear proof that $k > 1$. The use of pure uranium metal, however, gave such a decided improvement that no further doubt of a real increase in the number of neutrons ($k > 1$) was possible (about February or March 1942). Here then was the proof that the technical utilization of atomic energy was possible, and that the mere enlargement of the Leipzig apparatus must furnish an energy-producing uranium pile.

At the same time, important administrative changes were taking place. At a meeting held in the building of the Reichsforschungsrat in Berlin, on February 26, 1942, the results to date were reported to the Minister of Education, Rust, and several directors of war research. The uranium project was transferred from the Heereswaffenamt to the control of the Reichsforschungsrat; and the then president of the Physikalisch-Technische Reichsanstalt, Esau, was made responsible for the project. On June 6, 1942, there was a second meeting at Harnack House in Berlin, when the results of the uranium project were reported to Speer, as Minister for War Production, and to the armament staff.

The facts reported were as follows: definite proof had been obtained that the technical utilization of atomic energy in a uranium pile was possible. Moreover, it was to be expected on theoretical grounds that an explosive for atomic bombs could be produced in such a pile. Investigation of the technical sides of the atomic bomb problem—for example, of the so-called critical size—was, however, not undertaken. More weight was given to the fact that the energy developed in a uranium pile could be used as a prime mover, since this aim appeared to be capable of achievement more easily and with less outlay. As to the separation of the uranium isotopes, no method was known which would have allowed of the production of an atomic explosive without an enormous and therefore impossible technical equipment. Incidentally, the use of protoactinium as an atomic explosive was also considered, since its nucleus is fissionable by neutrons with energies down to 10^5 eV., with the consequent possibility of a fast chain reaction. It was, however, considered to be impracticable to prepare the necessary quantities of the element.

Following this meeting, which was decisive for the future of the project, Speer ruled that the work was to go forward as before on a comparatively small scale. Thus the only goal attainable was the development of a uranium pile producing energy as a prime mover—in fact, future work was directed entirely towards this one aim. Again during the summer of 1942, discussions were held with heat experts on the technical problems of heat transfer from the uranium to the working material (that is, water or steam). Technical experts from the Navy attended the meeting with a view to the possible use of a uranium power unit in warships. The Kaiser Wilhelm Institut für Physik was restored to the Kaiser Wilhelm Gesellschaft, with the author as director. In preparation for investigations on the larger uranium piles planned in the Institute, a spacious underground laboratory was added (Wirtz).

About this time, however, the strain of the War on the already overloaded German industry was making itself felt. Uranium and uranium slugs were produced in such small quantities that deliveries were late and the larger-scale experiments were repeatedly postponed. Nevertheless, important progress was made. As early as 1941, a research group at the Heereswaffenamt (Diebner, Pose, Czulius) had made measurements on a large pile built up as a lattice of uranium cubes in a paraffin matrix; the subsequent theoretical investigation (Höcker) demonstrated that the lattice construction could in certain circumstances show advantages over the layer arrangement. An experiment made by this group with a model pile of uranium cubes in D_2O-ice did, in fact, yield a larger increase in the number of neutrons than the Leipzig pile. In a later experiment, using 500 litres of heavy water, a further increase in the number of neutrons was recorded. Measurements made in the Heidelberg Institute with a small model pile defined the relation between the increase in the number of neutrons on one hand, and the thickness of the layers on the other; while experiments undertaken by Bothe and Flammersfeld at Heidelberg, and by Stetter and Lintner in Vienna, threw new light on the fission processes occurring in U(238). A theoretical investigation by Bothe stressed the importance of the 'stopping distance' (*Bremslänge*) for the minimum size of a self-sustaining pile.

In preparation for further experiments with larger quantities of heavy water and uranium metal, the Kaiser Wilhelm Institut für Physik in Berlin began a study of the effect of graphite and water as an outer cover for the pile. Resonance absorption in uranium had been studied by Volz and Haxel and by Sauerwein. Further, the absorption cross-sections of a series of different substances were measured by Ramm, as well as by Volz and Haxel at the Berlin Technical High School. As regards the question of thermal stabilization of the energy production resulting from the temperature broadening of the resonance lines, experiments by Sauerwein and Ramm with the Berlin-Dahlem high-voltage plant were significant.

In the spring of 1943, the Norsk Hydro electrolytic plant was put out of action in a Commando raid. Its reconstruction was begun, but finally the responsible army command in Norway reported that effective protection of the plant, particularly against air raids, was impossible. In October 1943 the plant was completely destroyed in a heavy air raid. Nevertheless, about two tons of heavy water were available in Germany at the time: a quantity which, according to our calculations, was just enough for the construction of an energy-producing pile. The Reichsforschungsrat had made no effective provision for the construction of a new heavy water factory in Germany, and the pilot plant at I.G. Leuna made slow progress. It was proving, in fact, barely possible, in view of air raids and the overall strain on German production, to undertake such big building projects. The production of uranium slugs came to a temporary standstill after the raids on Frankfurt in the spring of 1944.

Even then, some progress was achieved by the Harteck–Groth–Beyerle group. As early as 1942, this group had succeeded in developing an ultracentrifuge for the enrichment of the isotope U(235). It was planned to use uranium enriched with the rare isotope in the construction of improved uranium piles, possibly in conjunction with ordinary water. At about this time, the direction of the uranium project was transferred from Esau to Gerlach. Gerlach had taken over the physics section of the Reichsforschungsrat, and he strove to promote more particularly the scientific side of the uranium problem; and at that, not only the physical, but also the medical aspect. In connexion with the medical applications, the construction of a low-temperature pile, in liquid carbon dioxide, was undertaken on Harteck's suggestion. Such a pile, even of small dimensions, could be expected to yield profitable amounts of radioactive elements for tracer research, in view of the decreased absorption in the resonance lines at low temperatures.

In the winter of 1943–44, a model pile of 1·5 tons of heavy water and about the same weight of uranium plates was constructed in the Dahlem air-raid shelter through the co-operative efforts of the Kaiser Wilhelm Institutes for Physics in Berlin and Heidelberg (Wirtz, Fischer, Bopp, P. Jensen, Ritter). The number of neutrons injected from the internal source was multiplied by the factor 3, a performance approaching considerably nearer to what we called the *Labilitätspunkt*, at which the ratio k increases beyond limit and at which the uranium pile begins to radiate independently of the neutron source and thus to produce energy. The relation between neutron increase and layer thickness fulfilled expectations. Further, the stopping distances of the fission neutrons in carbon and heavy water were redetermined (Wirtz) and the former inexact measurements considerably improved. These experiments were made in the air-raid shelter of the Institute during the heaviest air raids on Berlin, and were naturally to some extent hindered by the raids. On February 15, 1944, the Kaiser Wilhelm Institut für Chemie received a direct hit. In the meantime, the Kaiser Wilhelm Institut für Physik had been partly evacuated to Hechingen. On the instructions of Gerlach, a cellar cut out of the solid rock, situated in the village of Haigerloch, was equipped for the rebuilding of the uranium pile. It was not until February 1945, however, that the greater part of the necessary material (about 1·5 tons of heavy water, 1·5 tons of uranium, 10 tons of graphite, cadmium for the regulating rods, etc.) was finally assembled at Haigerloch, and a new pile, this time built up of uranium cubes in heavy water, with an outer cover of graphite, constructed (Wirtz, Fischer, Bopp, Jensen, Ritter). A branch of the Reichsforschungsrat at Stadtilm was allotted the remaining quantity of heavy water and a great part of the available uranium. The Haigerloch pile yielded a sevenfold neutron increase. The material available at Haigerloch, however, was just insufficient to attain $k = \infty$. A relatively small amount of uranium would in all probability have sufficed; but it was no longer possible to obtain it, since transport from Berlin or Stadtilm could no longer reach Hechingen. On April 22, Haigerloch was occupied, and the material confiscated by the Americans.

When we compare the German work reported here with the corresponding Anglo-American effort, so far as it has been made known, then the beginning of 1942 seems to be the turning point. Up to that time, both sides were dealing predominantly with the scientific problem as to whether nuclear energy could be utilized at all, and what fundamental methods had to be employed to that end. Both sides had arrived almost simultaneously at very similar results, if one excludes the field of isotope separation, in which the Anglo-Americans had made much greater progress. Furthermore, in the United States far more attention had been given to laying the groundwork for subsequent full-scale development of the uranium project; so that the first self-supporting pile was functioning as early as December 1942.

It remained to determine the technical sequel to these results. In the United States, the final decision was taken to go for the production of atomic bombs, with an outlay that must have amounted to a considerable fraction of the total American war expenditure; in Germany an attempt was made to solve the problem of the prime mover driven by nuclear energy, with an outlay of perhaps a thousandth part of the American. We have often been asked, not only by Germans but also by Britons and Americans, why Germany made no attempt to produce atomic bombs. The simplest answer one can give to this question is this: because the project could not have succeeded under German war conditions. It could not have succeeded on technical grounds alone: for even in America, with its much greater resources in scientific men, technicians and industrial potential, and with an economy undisturbed by enemy action, the bomb was not ready until after the conclusion of the war with Germany. In particular, a German atomic bomb project could not have succeeded because of the military situation. In 1942, German industry was already stretched to the limit, the German Army had suffered serious reverses in Russia in the winter of 1941–42, and enemy air superiority was beginning to make itself felt. The immediate production of armaments could be robbed neither of personnel nor of raw materials; nor could the enormous plants required have been effectively protected against air attack. Finally—and this is a most important fact—the undertaking could not even be initiated against the psychological background of the men responsible for German war policy. These men expected an early decision of the War, even in 1942, and any major project which did not promise quick returns was specifically forbidden. To obtain the necessary support, the experts would have been obliged to promise early results knowing that these promises could not be kept. Faced with this situation, the experts did not attempt to advocate with the supreme command a great industrial effort for the production of atomic bombs

From the very beginning, German physicists had consciously striven to keep control of the project and had used their influence as experts to direct the work into the channels which have been mapped in the foregoing report. In the upshot they were spared the decision as to whether or not they should aim at producing atomic bombs. The circumstances shaping policy in the critical year of 1942 guided their work automatically towards the problem of the utilization of nuclear energy in prime movers. To a German physicist, this task seemed important enough. The mere possibility of solving the problem had been rendered possible by the discovery of th German scientific workers Hahn and Strassmann and so we could feel satisfied with the hope that the important technical developments, with a peace-time application, which must eventually grow out of their discovery, would likewise find their beginning in Germany, and in due course bear fruit there.

A LONG-TERM PLAN FOR THE NILE BASIN

EGYPT, an agricultural country with practically no rainfall, is entirely dependent on the annual flooding of the Nile. Under natural conditions only that part of the country could be cultivated which was reached by the flood waters, and as the bulk of the population was generally little above the subsistence level, a poor flood meant widespread famine. The area of cultivation could only be extended by irrigation of land not reached by the natural flood; that is, by constructing dams to raise the level of the water, without interfering with the maximum level of the flood further downstream. The study of this possibility was begun about 1890 by Sir William Willcocks, as a result of which a relatively small dam was built at Aswan. This was completed in 1902, but was soon found to be inadequate; no other suitable site could be found at the time and the Aswan dam was heightened in 1912. Since 1920 the study of the Nile Basin has been assigned to the Physical Department of the Ministry of Public Works, Egypt, under the director-general, Dr. H. E. Hurst, who has gradually pushed investigations farther and farther upstream to the head-waters of the river in Lake Victoria in Uganda and Lake Tana in Abyssinia. From 1931 onwards a comprehensive series of reports has been issued under the title "The Nile Basin"; the present volume, by H. E. Hurst, R. P. Black and Y. M. Simaika, is the seventh of the series*.

The earlier proposals considered only how to make the best use of the flood water year by year. Storage from one year to another on the Nile itself presented very great difficulties, partly because of the immense volume of storage required to allow for a run of poor floods, and partly because of the enormous loss by evaporation in Egypt. Consequently, a poor flood still caused very great hardship; the situation was not so bad as it might have been because the Nile draws its water from a very large basin, and the fluctuations of rainfall were not in general similar over the whole area; but this advantage is largely offset by the losses in the extensive marshes of the Sudd. The Bahr el Jebel, which carries the whole of the discharge of Lake Albert, averaging 25 milliards (thousand millions) of cubic metres a year, flows through the flat Sudan plain, where it loses nearly half its water by evaporation and transpiration. Owing to this loss, the contribution of the White Nile to the main stream is relatively unimportant, and the bulk of the water supply of Egypt has to be met by the Blue Nile alone.

The population of Egypt is increasing rapidly, and the only way to guard against future famine is to accumulate a reserve of water so large that it can provide against the worst succession of bad years to be expected on any reasonable basis. This reserve must be in regions where evaporation is relatively small compared with that in Egypt, where the volume of water can be increased to a sufficient extent without greatly increasing the evaporating surface, and far enough apart for the variations from year to year to be practically independent, so that runs of bad years would not be likely to coincide in all areas. The authors find that these requirements can be met by dams at Nimule below Lake Albert and at the outlet of Lake Tana, with possibly at a later stage a further reserve in Lake Victoria. The amounts of storage considered necessary, after allowing for the loss of some 40 per cent on the long journey to Aswan, are enormous; they vary slightly according to different details in the plans but roughly amount to 140 milliards of cubic metres in Lake Albert and Lake Victoria together, with afterwards another 40 milliards, and anything up to 17 milliards in Lake Tana. Compared with these figures the capacity of the first Aswan dam, one milliard cubic metres, is indeed "a trifling amount". In order to reduce the losses in the passage of the Sudd, it will also be necessary either to dig a diversion canal or to embank the Bahr el Jebel. The scale of the problem is shown by the length of the proposed canal—about 300 km. or nearly 200 miles. The ramifications are endless, ranging from consideration of the disturbance of dock and harbour facilities to the need to remove and rebuild churches. The cost would be very high, but against it must be set not only the livelihood of many more people in Egypt but also the prevention of flooding and the supply of hydro-electric power. These details are matters for a full engineering inquiry; but the authors have given a lead in what must be one of the most gigantic plans ever seriously put forward.

There is one detail which requires to be mentioned here. The authors repeatedly emphasize their idea of "Century storage", which briefly means that the reserve must be sufficient to deal with the greatest accumulated deficit to be expected in a hundred years. To obtain this figure, they examined a collection of about sixty long records of discharges, river-levels, rainfall, temperature and pressure, ranging from 10 up to as many as 200 years (with one river-level record of 400 years), and plotted the greatest accumulated departures from the mean values against the square root of the number of years. They write: "If we have N observations of an element whose standard deviation is σ, then if R is the maximum accumulated excess or deficit from the mean, on the average

$$R = 1{\cdot}65\,\sigma\sqrt{N}$$

. . . The form of this result is confirmed by theoretical investigations based on the theory of probability applied to the tossing of coins." Unfortunately, they do not give the theory, and the reviewer has not been able to find it anywhere in the literature of statistics; but the form of the expression seems to him to be incorrect. It is easily shown that in a series of values obeying the Gaussian distribution, the maximum possible accumulated departure is $0{\cdot}4\,\sigma N$, but the value of $0{\cdot}4\,N$ is less than $1{\cdot}65\sqrt{N}$ when N is less than 17. Thus, for a series of less than seventeen years, the authors' expression gives an expected departure greater than the maximum possible. Detailed calculation would be difficult; but one would anticipate that the maximum deviation expected in N years would bear a constant ratio to the maximum possible deviation, that is, $c\,\sigma\,N$, where c is a constant less than 0·4. Now the accumulated departures in Plate XII only appear to fit in with the $\sqrt{N}$ law because of one very aberrant figure for 400 years; all the remaining points are fitted much more accurately by the curve given by $R/\sigma = 0{\cdot}2\,N$. In a series of a hundred observations, this gives an accumulated departure 20 per cent greater than that estimated by the authors, and their "Century storage" reduces to 80-year storage. This is not actually a very serious matter, as the uncertainties of some of the other figures are probably equally great, but it might be seized on by opponents.

* The Nile Basin. Vol. 7: The Future Conservation of the Nile. By Dr. H. E. Hurst, R. P. Black and Y. M. Simaika. (Ministry of Public Works, Egypt: Physical Department Paper No. 51.) Pp. xi+178+27 plates. (Cairo: S.O.P. Press, 1946.) P.T. 125; 25*s*.

So great a plan will require a long time to come to fruition—time which includes not only the building of the great dams and digging of channels, but also the many years required to build up the reserves of water. Everything depends ultimately on the rainfall of the upper parts of the Nile Basin; but the existing knowledge of the amount of rain and its long-term variation has many gaps, especially in Abyssinia, which must be filled by the setting up of new rain-gauges, and this is one of the first necessary steps. So far as one who is not an engineer can tell, Dr. Hurst and his colleagues have considered all that has to be done and the order of priority, and this should be of great help in the discussion of ways and means.

C. E. P. BROOKS

REDUCTION OF FIRE RISKS IN SHIPS

THE Admiralty Chemical Department, Portsmouth, has been busy of late with research into methods of reducing the fire risk on ships arising from paints and other materials used in them. An interim report recently made available reveals that the investigations have followed three lines; namely, the development of fire-retardant paints for interior use particularly on metal surfaces, the fireproofing of textiles, and the fireproofing of plywood and soft timber.

Fire-Retardant Paints for Interior Use on Board Ship

Dried paint films on an organic base can be a powerful factor in transmitting fire, as experience during the War showed. Fire can be propagated from one compartment to another by means of the paint film on the bulkhead between them. Certain paint types when raised to a sufficiently high temperature—on the side of the bulkhead remote from the actual conflagration—blister and form pockets of inflammable vapours. These vapours arise from the partial decomposition of the organic paint medium in the interior of the paint layer. The blisters finally burst, emitting jets of hot gas which ignite spontaneously and burn vigorously, transmitting the fire to any combustible material within reach.

The method used by the Admiralty for evaluating the fire-retardance of paints to be used in such circumstances is as follows. A steel plate, of standard thickness and 12 in. by 12 in. in area, is painted on one side with a primer/top-coat system in the normal manner, adequate time being allowed for drying. The plate is then heated in the vertical position on the unpainted side, with a gas ring supplied with air and gas under standardized pressure. The plate becomes red-hot in about 30 sec. Heating is continued for one minute, by which time combustion of the paint film has largely ceased. Any signs of flashing or flame-propagation are noted, together with any tendency for the red-hot film to detach itself from the plate. This test differentiated decisively between paints of good and bad fire-retardance. Large-scale trials upon painted plates, 6 ft. square, were carried out at the Admiralty Fire Testing Ground, Haslar, and the results established the validity of the laboratory test-procedure.

The tests showed that fire retardance was improved by reducing the proportion of medium so far as was consistent with durability and finish, and that titanium and antimony oxides were particularly effective as pigments in the top coat. The primer used was also important, an aluminium pigmented primer being adjudged to have better fire-retardant properties than a red-lead primer.

A specification for such paints has been prepared which prescribes the type of medium and the minimum proportions of titanium dioxide and antimony oxide to be used, and the correct pigment/medium volume ratio. Fire-resistance and other performance tests are included. Such paint is now in service use, but it has disadvantages, notably its matte surface, and work is at present in hand on the development of a finish of good gloss and adequate fire-retardance.

The experimental conclusion that antimony and titanium oxides are better than the other white pigments tested is interesting, in so far as their behaviour in the heated film must be essentially different; antimony oxide is comparatively volatile and easily reducible on heating with organic matter (such as would be present in the film), and titanium dioxide is particularly inert. Whereas it is admitted that antimony compounds are particularly valuable fire retardants in conjunction with textiles, opinion is divided on the fire-retardant value of antimony oxide in paint; thus an American Report (New York Paint and Varnish Production Club, 1943) on an investigation into fire-retardant paints for steel surfaces says that while in the particular tests reported antimony oxide was useful in preventing flashing in paints of low pigment volume, in paints of high pigment volume (as recommended by the Admiralty) it was the worst of the white pigments examined.

An Inorganic Paint System

Since a paint based on an organic medium can never be entirely incombustible however high the degree of pigmentation achieved, the investigation of paints based on inorganic media was a logical step in the Admiralty investigations. Among the materials examined was cementiferous paint originally developed to make use of the excellent anti-corrosive effect of zinc on steel surfaces and consisting essentially of a zinc oxychloride cement containing a high loading of metallic zinc. Such paint showed great promise as a fire-retardant coating, but in its original form suffered from the following disadvantages: (1) It could not be stored in a ready for use form; it consists of two parts which had to be mixed immediately prior to application. (2) It was highly thixotropic and had poor flow properties. (3) Its colour was a dull grey which could not greatly be improved by the addition of white pigments.

It was found that the first defect could be overcome by the addition of an organic liquid as thinner. Thus 20 per cent by weight of industrial spirit enabled the paint to be kept indefinitely in a ready-for-use condition, and improved the film properties.

To obtain suitable decorative colours, it was, however, necessary to use the cementiferous paint only as an undercoat and to apply a top-coat in the desired shade. It was found that a partially hydrolysed silicon ester painted over a cementiferous primer gave a paint system which was quite incombustible with excellent weather-resistant and fire-retardant properties. When pigmented with titanium dioxide and barium sulphate the film was hard, matte and white; unfortunately, however, the pigmentation was found to affect the film-forming properties of the silicon ester in a discouraging and inexplicable manner. Whereas the pure medium gave continuous, hard and resistant films, the pigmented films tended to craze and crack on drying, and under the fire test small pieces flew off with considerable violence. Usually the cracking resulted in the under-coat being dragged away from the steel surface, and the whole film became faulty and brittle.

The next step was to consider the old problem of plasticizing the silicon ester paint, and di-butyl phthalate was the most satisfactory material. The films, although matte, did not craze or crack on drying or weathering and had excellent fire-retardant properties owing to the fact that the volatile dibutyl phthalate evaporated quickly when heat was applied, instead of charring and burning. Linseed oil was not so successful as a plasticizer.

The remaining problem in the use of silicon ester paints in the manner described was that of stability, for silicon ester medium, whether pigmented or not, shows a gradual increase in viscosity from the date of preparation until, after about three or four months, it sets to a hard gel. The common preserving agents, such as colloidal electrolytes, appear to be ineffective in this case, and the problem is one of great complexity.

The Admiralty has, in effect, met the customary stumbling-blocks in the use of silicon ester paints. Possibly some improvement may lie in the use which has recently been reported of stable silicon esters which are hydrolysed by the user just prior to application. It does not seem unreasonable to suppose that entirely adequate plasticizers for silicon ester will be found in the silicone field.

Fireproofing of Textiles

It was necessary that attention should be paid to the reduction of the inflammability of the many textile fabrics to be found on board ship.

A water-resistant fireproofing treatment is essential for materials such as ships' awnings, boat covers, etc., which are exposed to the weather, and is preferable for materials such as curtains which need to be laundered. Nevertheless a certain amount of fireproofing was carried out on ships by impregnation with water-soluble materials, borax–boric acid mixtures being preferred; reproofing after washing is necessary.

There is no simple method of producing an adequate water-resistant fireproofing treatment by deposition of insoluble inorganic materials in the fibres. Some metallic oxides, for example, iron and tin, which provide efficient flame-resistance when so deposited, unfortunately induce considerable after-glow.

In the Admiralty work the best results were achieved by impregnation with antimony oxide in conjunction with a chlorinated organic compound such as chlorinated paraffin or polyvinyl chloride co-polymer. The after-glow usually associated with such processes was reduced by the incorporation of zinc oxide or stannic phosphate to provide a fire-, water- and weather-resistant process suitable for application to cotton fibres and flax canvases. Large-scale trials demonstrated that the treated fabrics retained a fair degree of flexibility and were very nearly glowproof.

Owing to the somewhat copious evolution of smoke on ignition, it was found that the application of the process on fabrics normally situated between decks was restricted; but for canvas gear, for example, weather screens, etc., more or less permanently fitted on the weather deck, the process was strongly recommended.

In addition to the use of fire-proofing processes, attention was paid to the use of less inflammable textile materials. For example, consideration was given to the replacement of cotton by wool, nylon or alginate according to the circumstances. Glass-fibre fabrics proved insufficiently durable under sea-going conditions.

The report under review, taken with other information, shows that the war years have brought antimony oxide, previously neglected, to the forefront as a constituent of fire-proofing compositions on textiles. Antimony oxide, while of itself having only moderate fireproofing properties (it is not completely inert as suggested by the Admiralty report under notice), has greatly enhanced fireproofing properties in the presence of chlorinated organic compounds (usually attributed to the formation of antimony oxychloride), and also other materials such as iron oxide; and it is as a result of these discoveries that its use has been advanced.

Rapid Methods for Fireproofing Plywood and Soft Timber

In May 1944, work was commenced to devise an efficient method of fire-proofing small wooden articles such as, for example, plywood used in the construction of cases for radio equipment.

The standard method of fire-proofing wood in bulk by impregnation with mono-ammonium phosphate solution was found not to be very suitable owing to the relative slowness with which aqueous solutions are absorbed by wood; and moreover, in the case of plywood, the use of aqueous solutions would cause distortion through attack on the adhesives. This directed attention towards a fire-proofing agent which should be soluble in organic solvents, and in turn led to an examination of the suitability of organic phosphates for the purpose in view. Examination of a large range of materials showed that urea phosphate, which is readily soluble in alcohol, possessed good fire-proofing properties; and an alcoholic solution with a small proportion of wetting agent added was found to give the desired speed of impregnation.

The most satisfactory procedure involved simple immersion of the article to be treated in a hot solution (of 20–30 per cent strength by weight) of urea phosphate in industrial methylated spirits for approximately one hour. The excess was then allowed to drain off, and the article left to dry. Alternatively, though less satisfactorily, in cases where immersion is impracticable, a series of brush applications can be substituted. Large-scale trials at the Admiralty Fire Testing Ground, Haslar, confirmed the efficiency of the process, which has been patented and assigned to the Admiralty.

NEWS and VIEWS

International Council of Scientific Unions

Executive Committee's Annual Meeting

THE Executive Committee of the International Council of Scientific Unions held its annual meeting in Paris in July at U.N.E.S.C.O. House under the chairmanship of Prof. Němec of Prague. Dr. Laves, deputy director-general of U.N.E.S.C.O., in welcoming the Committee, stressed the importance that U.N.E.S.C.O. attached to mutual international understanding and to the well-being of all the nations of the world. He hoped that the Committee would devote some attention to the social implications of science. Nine international scientific Unions were represented at the meeting, including two new Unions which had been admitted as adhering organisations during the previous twelve months—the International Unions of Crystallography and of Theoretical and Applied Mechanics. A tenth Union was admitted at the meeting, the International Union of the History of Science. No new Joint Commissions between the Unions were formed, but instead it was agreed that one Union should form a committee in a border-line subject and invite other interested Unions to nominate members of the Committee. In the same way, it was agreed to allot each of the existing Joint Commissions to a parent Union, which would be primarily responsible for controlling and helping its activities. The Unions were still feeling their way to the best method of helping forward border-line subjects, but one point was clear—representatives of a particular science should be nominated by the appropriate Union, not co-opted by the parent body. Thus a committee on radio-biology in the Union of Biological Sciences would include members nominated by the Unions of Physics and Chemistry.

The Committee expressed gratitude to U.N.E.S.C.O. for grants totalling more than 200,000 dollars to the Council and the various Unions to meet travelling expenses of delegates, to finance well-established international scientific organisations and to meet certain costs of publication and of administration. M. A. Establier was re-appointed liaison officer between the Council and U.N.E.S.C.O. for 1948. Reports were received from the Unions, Joint Commissions and the Committee on Science and Social Relations. These will be published with the report of the Committee to the organisations adhering to the Council.

Report of the 1946 General Assembly

EDITED by Prof. F. J. M. Stratton, general secretary, the Reports of Proceedings of the Fourth General Assembly of the International Council of Scientific Unions, held in London during July 22–24, 1946 (see *Nature*, August 17, 1946, p. 227), has now been published (London: Camb. Univ. Press, 1946). It includes the presidential address of Prof. H. R. Kruyt and of the proceedings at the general assembly, together with the reports of the international unions. Appendixes include a list of delegates, the report of the executive committee and the draft agreement with the United Nations Educational, Scientific and Cultural Organisation, the financial report, the statutes of the International Council of the Scientific Unions and the scientific unions themselves. The names of the members of the mixed commissions and of the officers of the international unions are also given, making the report a useful reference book; while in addition to the report of the Committee on Solar and Terrestrial Relationships, there is also reprinted the report of the Committee on Science and its Social Relations on the public attitude of scientific bodies with regard to the problems raised by recent applications of science.

The report of the Committee on Science and its Social Relations points out that the problem of nuclear energy takes the foremost place at present in all discussions on the relation between science and society, although biochemistry, biology, bacteriology and aerodynamics will present questions of almost equal importance. Emphasizing that science thrives best in an atmosphere of freedom of thought and co-operation, and that the widest interchange of information is vital to its full development, the report urges that the imposition and control of any necessary restrictions of secrecy should be exercised only by constitutional authority and in consultation with, and under the guidance of, representative scientific opinion. The increasing social importance of science must be recognized by scientific workers themselves as fully as by governments and administrators, and it is part of the duty of men of science to urge that the problems of government and administration should be rationally formulated and attacked. They must, collectively and individually, bring to the solution of these problems their devotion to truth and their unswerving, objective and critical search for facts and their interrelations.

York as a University City

IN a letter dated July 8, 1947, which is addressed to those who have expressed interest in the project of a university foundation in York, the Lord Mayor makes clear the policy being pursued by the University Grants Committee. Although that Committee has expressed agreement with the view "that the City of York is in many respects well suited to be a centre of university education", it has drawn a rigid line between the "short-term" and the "long-term" prospect. It appears that immediate prospective needs can, in the opinion of the Committee, be met by plans for the extension of existing university institutions—"provided they can be assured of additional academic staff in sufficient numbers and of the means of carrying out an extensive programme of new building." Clearly, therefore, the University Grants Committee has already determined that, whether at York or elsewhere, there is little case for the establishment of a new university centre "at any time in the near future". It is, of course, as the Committee points out, open to the local community to proceed to work out the details of a scheme which might form the basis of a long-term policy, should conditions materially change after five or ten years; and it is encouraging to know that an executive committee has already been set up in York to undertake the preparation of detailed plans.

A National Council for Further Education

As a step towards the further implementation of the recommendations made in the report of the Percy Committee on Higher Technological Education, the Ministry of Education has set up a working party to consider the functions and institution of a National Council to co-ordinate the work of Regional Advisory Councils for Further Education. The members of the working party are: Mr. D. R. Hardman, parliamentary secretary to the Minister of Education (*chairman*); Mr. C. N. Gallie, Mr. F. W. Lawe, Mr. S. Hurst, Captain A. M. Holbein, Mr. H. S. Magnay, Dr. J. E. Myers, Prof. E. A. Owen, Prof. R. E. Priestley, Dr. H. Schofield, Sir Charles Tennyson, Mr. T. B. Wheeler, Mr. F. Bray, Mr. H. J. Shelley, Mr. I. O. McLuckie (*secretary*).

Current Aspects of Sociology

THE issue of *Pilot Papers* for March 1947 (2, No. 1), is an admirable mixture of the methodological, the statistical, the philosophical and the human interest in sociology, all of unusual calibre and neatly compèred by Mr. Charles Madge. Two statistical articles illustrate how statistics may lay bare truths obscured by wishful thinking. For example, Mr. J. F. S. Ross shows, as against popular misconception, that the present House of Commons is little younger than previous Houses, and Dr. Grace Leybourn-White that only one in five of those with an intelligence quotient of 124 or more (equal to that of the best half of Manchester students) actually reach the universities. The philosophical contribution by Dr. H. W. Singer (incidentally a statistician) reflects upon social progress, and rightly questions the popular, and sometimes academic, view that economics is wholly concerned with material wealth and prosperity. Human interest is supplied by E. L. Packer's "Aspects of Working-Class Marriage". As a probation officer, he brings wide experience; but clearly the stage is not yet set for even a statistical *estimate* of the relative frequency of the various patterns of marital life he discloses. In Mr. Willson Disher's "Penny Dreadfuls", with many of the original illustrations and three chapters from the "Blue Dwarf", human interest is at highest pitch.

Among the 'coldly' scientific, however, it is the methodological article by Tom Harrisson on "What is Sociology" that will arouse most interest. He cries plague upon both the purely philosophical and deductive, and the purely statistical and inductive approach in sociology. But surely, while deduction and philosophy have little use for mass-observation, statistics are perfectly compatible with it? Statistical measurement is indeed logically the next stage in induction after observation, not a rival method at the same stage. Mr. Harrisson should have every support in insisting on more 'penetrative' observations; but after that, how can mass behaviour be summed up or the relative frequency of its various patterns be estimated except by statistics? While supporting statistics, he should urge that we ought to be less eager to rush into statistics before making sure of the stuff our statistics are made of. Occasionally, too, he is unfair—particularly so to industrial psychologists and sociologists. They are not talking of incentives merely now that it is fashionable, as a new discovery. On the contrary, if Mr. Harrisson will look at the index of books on industrial fatigue so far back as 1923, he will find 'incentives' with many references; or let him read some of the inter-war reports of the Industrial Health Research Board. The industrial psychologist has, in fact, been for many years a voice crying in the wilderness.

German Hydrographic Journal

A NEW journal is to be issued by the German Hydrographic Institute, now at Hamburg, under the title *German Hydrographic Journal*. This will be the medium for the publication of articles on those branches of science which are the concern of the German Hydrographic Institute; such as coastal and open sea surveying, nautical science, navigation, chronometry, terrestrial magnetism, ship's magnetism, nautical technique, tides, and physical and chemical oceanography—the latter including reports on the geology and lithology of the sea-bottom. The *Journal* will, in effect, so far as the subjects named are concerned, take the place of the former *Annalen der Hydrographie und Maritimen Meteorologie*, which were published by the German Admiralty during 1873–91, and thereafter by the Deutsche Seewarte up to 1944. Maritime meteorology and climatology, being now the concern of the Meteorological Office for North-Western Germany, will be dealt with in the new journal only in so far as they affect oceanography. Generally, each issue will contain articles on a variety of the subjects named above, and will include also notices on hydrographic institutions and other related matters. In addition, notices and reviews of publications of interest to the Institute will appear in the pages of the journal, together with a current bibliography relating to the special fields of research enumerated. An ultimate aim is gradually to list all relevant German and other publications which have appeared since the autumn of 1939, though such a bibliography cannot be compiled in proper time sequence. The journal will appear under the supervision of Dr. G. Boehnecke (who is the German director of the Institute), and will be edited by Dr. Arnold Schumacher.

Science in Poland

ACCORDING to a writer, Prof. Adam Malicki, in the new Polish monthly review, *Zycie Nauki*, May 1946, two plans are now being considered in connexion with science in Poland. One envisages the transforming of certain Polish universities (there are seven at present functioning) into higher professional training schools; the other involves an increase in the number of research institutes outside the universities. Past experience is said to have led to the conclusion that the acquisition of knowledge in a certain subject by a student is of less value than the gaining of an insight into the methods of scientific investigation and the solving of special problems. These objects can be best achieved by constant contact with creative men of science and by team-work in research. There may be difficulties in filling immediately all the posts at Polish universities, but their proper functioning is a matter of urgency on account of the large number of students enrolled. Another contributor, Dr. J. Parnas, urges that all research institutes should be placed under the supervision of the Polish Academy of Science and Letters, which should co-ordinate all investigations.

Zycie Nauki, which gives an idea of the outlook for science in Poland, is edited by Mr. M. Choynowski of Cracow, who states that in future the journal will contain a short review in English of scientific life in Poland. In this issue there is a summary of information on atomic energy taken mainly from the *Economist* and *Discovery* and reference is made to the cultural co-operation of the British Council and to its *Monthly Science News* and the *British Medical Bulletin*. Another article, by Stanislaw Liwszyc-Tomasik, is devoted to "the organisation of medicine in Great Britain", which the author thinks has undergone considerable change during the last two or three decades.

Medical Rehabilitation

A BOOKLET published by the Ministry of Health entitled "The Road Back to Health" (H.M. Stationery Office, 1947. 6*d*.; 7*d*. including postage) describes the process called rehabilitation by which injured or sick people are cared for, right from the beginning, with the object of returning them eventually to as full a measure of health and activity as is possible. The booklet tells its story well, and readers of it will be surprised by the degree of useful activity and happiness which can nowadays be conferred upon people whose injuries or illnesses used to cripple them and hasten the end of life. Excellent photographs show patients undergoing this continuous and beneficial treatment, facilities for which are available now at more than three hundred hospitals in England and Wales. Nobody can look at these or read the text of this booklet without commending both the present work and the plans for its future which are outlined in a concluding chapter. The booklet is intended chiefly for hospital authorities, doctors, employers, welfare workers and others closely associated with the care of the sick and injured; but the co-operation of everyone in this work is required, and especially that of the patient, so that the more the general public learn about it the better. The loss of a lung or an apparently irremediable injury of a vital limb or joint need no longer condemn either man, woman or child to be a life-long cripple or dependent on others. Modern medicine and surgery have given us in recent years many spectacular benefits of mankind and most of them have been well and extensively interpreted to the public. Rehabilitation is not so well known or understood. It depends upon the patient and highly skilled co-operation of doctors, nurses and others, and cannot succeed without the active help of the sick or injured person. It is a service to mankind which must be classed as one of the greatest achievements of modern times.

Seismology at Oxford

MISS E. F. BELLAMY, well known for her seismological work, has retired from her post as assistant at the Oxford University Observatory. It is hoped that she will enjoy a long and congenial retirement. The connexion between the Oxford University Observatory and seismology which was effected by the late Prof. H. H. Turner, enhanced by Prof. H. H. Plaskett and cemented by Miss Bellamy and others is being severed. The centre, where the calculations are done before the publication of the International Seismological Summary, has already been moved, by courtesy of the Director of the Meteorological Office, Air Ministry, to Kew Observatory, Richmond, Surrey.

The two Milne-Shaw seismographs belonging to the British Association Seismological Committee have been moved to Charles Darwin's old home at Down House, Downe, Kent (latitude 51° 19′ N., longitude 0° 4′ E.) and put in charge of Dr. O. J. R. Howarth, who, until recently, was secretary of the British Association for the Advancement of Science. Dr. Howarth is setting up the instruments on pillars in the basement of the house and hopes to bring the seismographs into use shortly. Down House is situated on a clay-with-flints cap over the chalk of the North Downs.

Weather Control Predicted

Sky and Telescope for April contains a short note on this subject in connexion with an address by Dr. V. K. Zworykin before the U.S. Institute of Aeronautical Sciences. He pointed out that new electronic calculators will yield rapid results regarding weather forecasts, and it may be possible to alter the weather by the release of a relatively small amount of energy which will have a 'trigger' effect. One method suggested is to spread a large amount of oil on water and ignite it; the resulting updraught would then change the motions of the higher-level air masses. Another method would utilize solar radiation at 'weather control areas', these consisting of large absorbing areas blackened by carbon deposits. These could be easily changed when desirable into highly reflecting areas by the formation of artificial fogs.

Announcements

MR. N. B. KINNEAR, the well-known ornithologist, keeper of zoology in the British Museum (Natural History) since 1945, has been appointed director of the Museum in succession to Sir Clive Forster-Cooper, who retires on October 1.

NATIONAL RESEARCH CORPORATION, Cambridge, Mass., in co-operation with the Division of Industrial and Engineering Chemistry, American Chemical Society, is arranging a symposium on "High Vacuum" to be held in Cambridge, Massachusetts, during October 30 and 31. Attendance will be restricted to technical and scientific personnel concerned with industrial applications of high vacuum. A report and the papers will be published in due course in *Industrial and Engineering Chemistry*. The secretary of the symposium is Mr. Stanley Heck, National Research Corporation, Cambridge 42, Massachusetts.

PUBLICATION No. 15 of Messrs. C. A. Parsons and Co., Ltd., Heaton Works, Newcastle-upon-Tyne 6, is an illustrated four-page pamphlet describing the Sir Howard Grubb, Parsons and Co.'s infra-red gas analyser, the operation of which depends on the fact that most of the common gases have strong absorption bands in the infra-red region of the spectrum. Each instrument is complete with one detecting unit filled with a particular gas, but additional units filled with other gases can be supplied and the replacement made by the user in a minute or two. Gases which can be estimated with the apparatus include carbon monoxide, carbon dioxide, methane, ethylene and other hydrocarbon gases.

WE regret to announce the following deaths:

Dr. John Parkinson, known for his geological work in various parts of Africa, Trinidad, India and Burma, on July 19, aged seventy-five.

Mr. R. I. Pocock, F.R.S., superintendent of the Zoological Society's Gardens, London, during 1904–23, on August 9, aged eighty-four.

Sir William Thomson, professor of mathematics in Victoria College, Stellenbosch, during 1883–95, principal of the University of the Witwatersrand, Johannesburg, during 1924–28, on August 6, aged ninety.

Prof. W. W. Watts, F.R.S., emeritus professor of geology in the Imperial College of Science and Technology, London, on July 30, aged eighty-seven.

Abnormal Flower Development in Barley Involving Sex Reversal

Reports have appeared in the press of widespread sterility in barley grown in East Anglia, and crop failure has been feared. The appearance of 'multiple ovaries' was noted by A. W. Punter, as reported by F. G. C. Fison[1]. Specimens of such abnormal ears were sent to us by Mr. Punter on July 10, which, on examination, disclosed the following facts.

About half the spikelets in the affected ears contained swelling grain and appeared to be normal. The sterile spikelets are easily distinguished from these by the widely opened glumes, exposing one or more undeveloped 'ovaries'. The presence of the rachilla indicates that not more than one flower is concerned. Supernumerary 'carpels' from one to three are present, and there is little doubt that these constitute the staminate whorl of the flower. In various flowers transitional stages were found between normal functional and fertile anthers and completely 'metamorphosed' stamens with many of the characteristics of carpellate structures. In Fig. 1 such a series is pictured. Fig. 1 (*a*) represents a stamen taken from a spikelet of normal aspect with swelling grain; the stamen when examined was nearly empty and had presumably produced fertile pollen. The peculiarity of the stamen is the appearance at the distal end of unusual simple hairs similar to those found normally on the carpel, and thus suggests the first stage of transition from a normal anther to a carpellate structure. In 1 (*b*) the stamen shown has, in addition to the unbranched hairs already referred to, 'stigmatic hairs' at the apex. In this stamen a few pollen grains were seen at the time of examination; but the flower was sterile and the glumes wide open. In 1 (*c*) the transition has proceeded further; there was here no sign of pollen, and the anther lobes are expanded as a white swollen tissue resembling that of the apical portion of a normal ovary. In all these cases the filament is long and thread-like as in the normal stamen, but in 1 (*d*) the filament is shortened and thickened. In 1 (*e*) the 'stamen' superficially resembles a normal ovary, but the ovary wall has not fused at the edges and is a hollow cylindrical sac without trace of an ovule: in no instance so far has any ovule been found in such a 'carpellate' stamen, though it is not absent from the accompanying ovary of the flower.

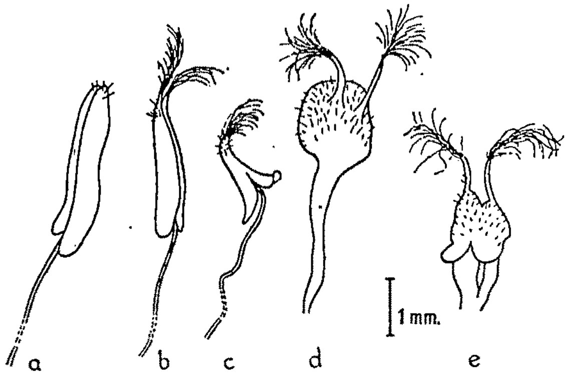

Fig. 1. A SERIES OF STAMENS SHOWING PROGRESSIVE TRANSFORMATION FROM NORMAL TO 'CARPELLOID' DEVELOPMENT

(*a*) Nearly normal stamen with a few simple hairs characteristic of the normal carpel. (*b*) Stamen with normal lobes bearing stigmatic hairs and simple hairs; some pollen formed. (*c*) Stamen with lobes distorted and hypertrophied; pollen absent. (*d*) Stamen with much-shortened and thickened filament and lobes replaced by a shapeless mass of tissue resembling the colourless tissue below the stigma of the normal ovary. (*e*) 'Carpelloid' stamen with flattened filament shortened to a hollow cylindrical sac resembling the ovary wall. Edges of 'filament' unfused

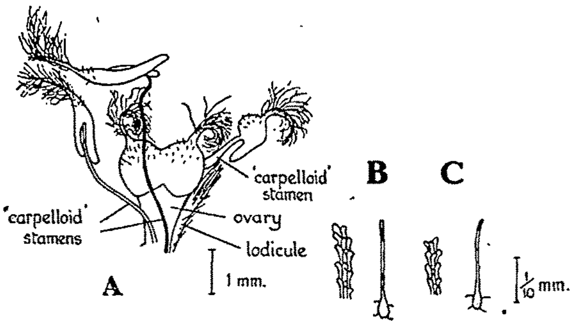

Fig. 2. *A*. COMPLETE ABNORMAL FLOWER SHOWING NORMAL OVARY, THREE CARPELLOID STAMENS AND ONE LODICULE. THE ORIENTATION OF THE STAMENS SHOWS THE ANTERIOR ANTHER TO BE MOST CARPELLATE IN FORM

B and *C*. SIMPLE AND STIGMATIC HAIRS FROM 'CARPELLOID' STAMEN AND OVARY

In Fig. 2 *A* is shown a complete abnormal flower with one of the lodicules, three 'metamorphosed' stamens, and a normal ovary. Fig. 2 *B* shows a 'stigmatic hair' and a simple hair from a carpelloid stamen, and, for comparison, in 2 *C*, similar hairs from the ovary. The identity of the hairs in the two cases emphasizes the resemblance between true ovary and the abnormal staminal structures. Considerable variation occurred in the relative development of the true and 'false' ovaries; in a few cases the structures were of equal size and then indistinguishable in external appearance.

The occurrence of these abnormal flowers was widespread in the barley fields of East Anglia, but similar abnormalities were also observed by Dr. H. K.

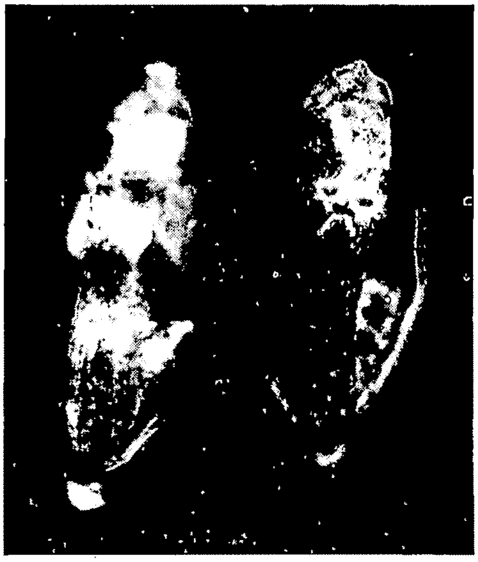

Fig. 3. SWELLING GRAIN TO WHICH IS ATTACHED THE ANTERIOR CARPELLOID STAMEN IN THE FORM OF A 'FALSE' OVARY' WITH WELL-DEVELOPED STIGMATIC SURFACE. (× 5)

Porter in experimental cultures of pure-line Spratt Archer grown at Rothamsted in connexion with other work of the Institute of Plant Physiology. Here the separation of the glumes was very marked, accompanied by bending over of the whole ear. The sterile spikelets were exactly like those described above; but in one open spikelet a normal swelling ovary was found accompanied by two small fruits which, however, contained no seed. Spikelets with swelling grain in abnormal ears showed in nearly every case some distortion of the stamens, some of which, however, must have been fertile.

During the past week, in company with Mr. Punter, one of us has examined the present state of the barley over a wide area of Suffolk. The amount of damage caused by the abnormal flower development was found to be quite small. Many of the sterile flowers have now died off but still show on examination remains of the 'carpelloid stamens'. In spikelets adjoining these, swelling grains were sometimes found in which one of the 'carpelloid stamens' persisted closely adpressed and partially fused with the swelling grain and with the white stigmatic tissue still very evident (Fig. 3). These supernumerary 'carpels' were all sterile, but must have responded to the growth stimulus of pollen which was found adhering to the 'stigmatic' hairs. Quite similar grains have been observed in the material from Rothamsted. It thus appears that if any pollen at all is produced in the spikelet, normal development of the ovary follows by self-fertilization and the glumes remain closed. In cases in which no fertile pollen at all is produced, swelling of the tissue below the stigma separates the glumes, and cross-pollination may be effected. The opening of the glumes, which undoubtedly first directed attention in the field to the abnormal floral structures, appears to be a secondary effect of failure of self-pollination, and not a direct effect of the abnormal floral development. That the ovaries of such abnormal flowers can be fertilized and produce normal grain is undoubted, and in consequence the pessimistic reports of the harvest prospects have fortunately proved in large measure groundless.

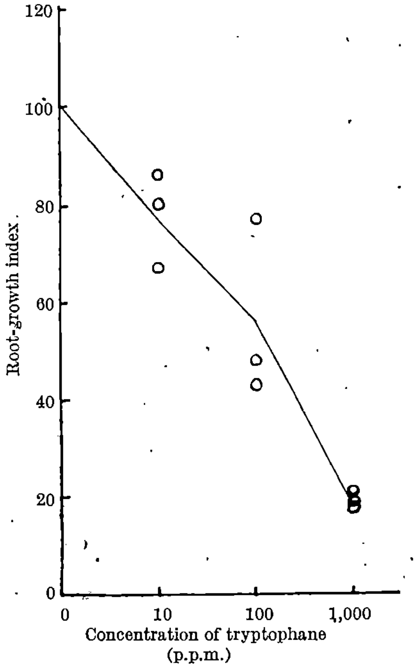
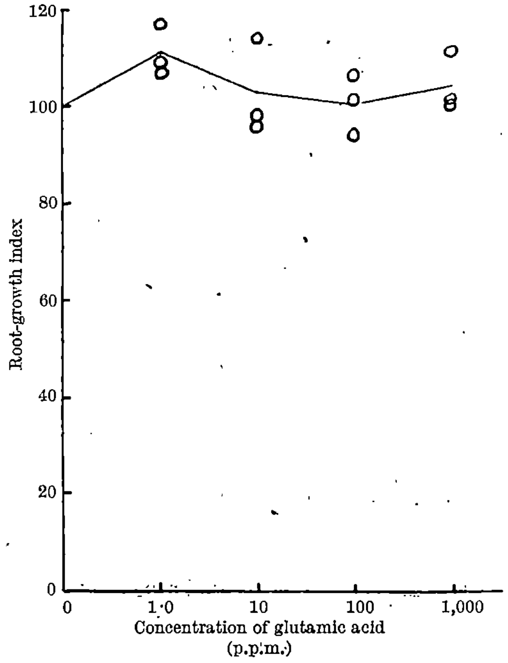
Toxic Effects of Amino-Acids and Amines on Seedling Growth

DURING the course of experiments on the effect of small concentrations of certain normal metabolites on seedling growth in sterile culture solutions, it has become apparent that a large number of amino-acids and amines have a distinct, and in some cases considerable, toxic action on the growth of cress roots. Experiments have been carried out using the technique described in a previous communication[1]. Sterile cress seeds were grown under rigidly sterile conditions in a range of concentrations of the compounds under consideration, together with controls in normal culture solutions. The various concentrations and controls were usually set up in triplicate, samples of 20 seeds being used in each tube. After a period of 7–10 days growth at 20–22° C. in artificial light (9 hours per day), percentage germination and total weight of roots produced were found for each concentration. From these values the root-growth index was determined. This is equal to

$$\frac{\text{Average weight of roots per seedling in presence of inhibitor}}{\text{Average weight of roots per control seedling}} \times 100$$

and gives a direct indication of the degree of inhibition. Graphs were afterwards constructed relating these values to the concentrations of the substances under consideration.





Two such graphs of root-growth index plotted against a logarithmic scale of increasing concentrations of glutamic acid and tryptophane are given in the accompanying figures. From these graphs it will be seen that glutamic acid exerts no toxic action on root growth up to the highest concentration of 1,000 parts per million. There is even the suggestion of a stimulation at the lowest concentration of 1 part per million. Tryptophane, on the other hand, is definitely toxic at 10 parts per million, the inhibition reaching a value of 80 per cent at the highest concentration of 1,000 parts per million. From graphs such as these, estimations of the relative powers of inhibition of a fairly comprehensive selection of compounds have been obtained and appear in the accompanying table.

Substance	Concentration at which inhibition is detectable (in p.p.m.)	% inhibition of root growth at a concentration of 1,000 p.p.m.
dl-α-Alanine	> 1,000	0
l-Glutamic acid	> 1,000	0
Glycine	100	50
Benzoyl glycine	> 1,000	0
l-Aspartic acid	100	15
dl-Proline	100–1,000	30
d-Arginine	100	30
p-Aminobenzoic acid	100	65
p-Acetylaminobenzoic acid	1,000	14
o-Aminobenzoic acid	10	94
o-Acetylaminobenzoic acid	100	81
p-Aminophenylacetic acid	100	75
p-Aminophenylbutyric acid	100	35
l-Tryptophane	< 10	80
Tryptamine (β-indole-ethylamine)	10	51
Nicotinic acid	10	40
Nicotinamide	10–100	35
Urea	100	75

The following points of special interest are apparent from this table.

(1) The only two normal metabolites so far investigated and mentioned in the table that have no detectable inhibitive action on root growth up to a concentration of 1,000 parts per million are α alanine and *l*-glutamic acid.

It is very suggestive that these two acids are highly active in transaminase systems[2,3]. It is not impossible that other amino-compounds may effect their inhibitions on root growth by competitive interference in the normal transaminase systems of the plant. Further experiments are being undertaken with these possibilities in mind.

(2) Glycine, surprisingly, shows a considerable inhibitive action, but this disappears entirely in the substituted benzoyl glycine (hippuric acid), suggesting that the $-NH_2$ group is essentially concerned in the inhibitive action.

(3) This latter suggestion is partially borne out by results from the amino-benzoic acid series of compounds, where the acetylamino-compounds are seen to be definitely less toxic than the parent amino-compounds. There is a possibility that some hydrolysis may have taken place in the solutions of the acetylated compounds, and that the toxic action observed is due to small amounts of the amino-benzoic acids thus produced.

(4) Tryptophane and tryptamine are known to produce certain physiological actions on plants similar to those produced by the auxins[4,5]. It has always been assumed that these effects are due to the formation from these substances of β-indoleacetic acid (heteroauxin) in the plant tissues subject to their action. In our experiments commercial preparations of tryptophane were used, and it is therefore possible that the observed inhibitions may be due partially to impurities in the form of β-indoleacetic acid. On the other hand, it is most likely that the molecules themselves have a considerable toxicity quite apart from the action of any such impurities that may be present.

(5) It is of much interest that molecules such as urea and nicotinic acid have relatively strong inhibitive effects on seedling growth. Conceivably this is connected with the presence of basic groups in the molecules.

To summarize, a most important feature of these results is the fact that many of the inhibiting compounds are normal plant metabolites. This illustrates the complexity of the problems centred around the nitrogen nutrition of the plant. How far these phenomena will enter into questions concerning organic manuring and the specific effects on plants of organic nitrogen molecules in the soil is a subject for future research.

Flowering Responses in a Strain of *Orobanche minor*

AN interesting case of the dependence of flowering on length of day has been found in *Orobanche minor* growing on red clover. In the first place, data obtained by one of us (P. S. N.) suggested that the time of flowering of this parasitic plant was synchronous with that of the host plant, and was to a large extent independent of the sowing date of the parasite. Late-flowering Montgomeryshire red clover seed was sown at six-weekly intervals from November 1945 until June 1946; *Orobanche* seed was added, through glass tubes already in position in the soil, in some treatments concurrently with the clover seed and in others at each subsequent six weeks interval. The November-, January- and February-sown clovers all flowered in early August, the *Orobanche* appearing in August, September and October, almost independently of the time of sowing of the parasite. The April-, May- and June-sown clovers flowered September to October, and the *Orobanche* attached to them appeared at about the same times.

Clover is a long-day plant, and if it is sown either in spring or the previous autumn it normally flowers in July, August and September, according to the earliness of the variety. In order to study the possible influence of day-length on the flowering of the *Orobanche* an experiment was set up (by M. H.) in 1946, in which pots of clover and *Orobanche* sown in February were exposed to 11 and 16½ hours of controlled day-length. The *Orobanche* was planted at a depth of 2 in. in the soil and was not, therefore, itself exposed to alternating light and darkness.

In short days the clover plants remained vegetative throughout the experiment and were compact and small-leaved. In long days they soon became tall and lax with long petioles, and came into flower in July after 106 days of treatment. *Orobanche* inflorescences appeared only in sets exposed to the long days, the first spike after 134 days exposure and two others later. The experiment was terminated on August 15, when the total number of *Orobanche* plants found in each treatment, by washing the clover roots free of soil, was 23 in short and 21 in long days. In short-day treatments none of the *Orobanche* plants displayed any signs of flowering on dissection of the growing apices; but of those from long days, in addition to the three already mentioned, seven plants were found to have flower primordia present.

In 1947 a second experiment entirely confirmed these results. It was further observed that the time of germination of the seed and parasitization by the *Orobanche* were independent of day-length. It thus appears that the *Orobanche* on clover does not initiate flowers unless the host is also in the flowering condition.

The times of flowering recorded in the British Flora of Bentham and Hooker for other members of the Orobanchaceæ are consistent with the view that they, too, are synchronous with their host plants in their time of flowering. This relation, however, cannot be postulated for all parasitic flowering plants, for we have shown that *Cuscuta europœa*, L. and *C. gronovii* Willd. flower independently of day-length and independently of the flowering of the host.

On the assumption that flower initiation in the host is controlled by a specific flowering hormone, this is produced only in long-day treatments, must be present in the root, and either it or a precursor appears to be transferred to the tissues of *Orobanche minor*, in which flowering is induced.

A full account of these experiments is being published elsewhere, and studies of *Orobanche* in controlled day-lengths are being continued.

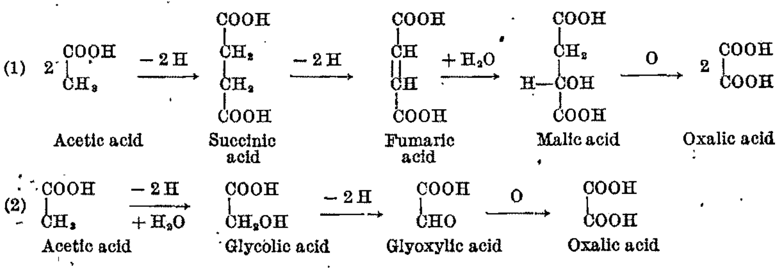
Enzyme Studies on the Mechanism of Wood Decay

Previous studies of the metabolic activities of a group of wood-destroying moulds (*Merulius niveus*, *M. tremellosus*, *M. confluens* and *Fomes annosus*) established the formation of ethyl alcohol, acetaldehyde, acetic and succinic acids by their action on cellulose, glucose and/or xylose[1]. Inasmuch as acetic acid has been shown to be the last breakdown product which can be isolated of the carbohydrate metabolism of these fungi, it was thought of interest to investigate the dissimilation of acetic acid, in the form of sodium acetate, to elaborate the complete phase sequence of wood-cellulose degradation by these moulds.

It was found that oxalic acid is the terminal product of the action of these organisms on acetic acid. The formation of oxalic acid from acetic acid being established, it remained to clarify the pathway of its origin. The discoloration of resazurin when incorporated in the acetate medium, together with a positive test for succinic acid, while pointing to an oxidation of the latter to give rise to oxalic acid, did not exclude the possible simultaneous formation of the acid through another route, since glycolic acid could also be regarded as a dehydrogenation product of acetic acid. Consequently, it was assumed that the discoloration of resazurin indicated a dehydrogenation of acetic acid resulting either in succinic acid, glycolic acid, or both. It would be conceivable, therefore, that *two* pathways can be taken during the formation of oxalic acid from acetic acid, namely:



The action of the *Merulii* and *Fomes annosus* on the following acids was studied: acetic, glycolic, lactic, pyruvic, succinic, fumaric, malic, dimethyl succinic and dimethyl fumaric acids. With the exception of *Merulius confluens*, the organisms were able to produce oxalic acid from all of the acids. It appears, therefore, that the phase sequence of acetate → oxalate transformation proceeds along the pathways outlined above.

Since the same metabolic products (ethyl alcohol and acetic acid) have been obtained from cellulose, glucose and/or xylose by the action of these organisms, we venture to postulate a mechanism for the breakdown of the cellulosic fraction of wood by the action of these moulds. Accordingly the following represents a picture of the sequence of the degradation of cellulose of wood when attacked by these fungi:

Cellulose → Glucose → Ethyl alcohol → Acetic acid → Oxalic acid.

Another mould, *Lentinus lepideus*, also was found to attack wood[2]. On the other hand, we observed that glucose and xylose, too, give rise to methyl-*p*-methoxycinnamate as a metabolic product besides ethyl alcohol during the utilization by this fungus. These findings corroborate the concept of the degradation of the cellulose of wood *via* an introductory hydrolysis when it is decomposed by micro-organisms, since it is only through such a split of the cellulose that glucose can arise as a primary dissimilation product. Then by further action of this mould the synthetic product is formed *via* the free hexose. The facts that xylose (a pentose) also gives rise to the ester, and that ethyl alcohol, obtainable from both glucose and xylose, is rapidly dehydrogenated, prompts the consideration of the transient formation of a C–2 compound in this synthesis which was found to be acetaldehyde. Experiments in which the further transformation of the acetaldehyde was prevented by trapping failed to give rise to the cinnamate.

The similarity between the structure of methyl-*p*-methoxy cinnamate and certain breakdown units of lignin[3] emphasizes the significance of the enzymatic synthesis of the former from acetaldehyde, for the better understanding of the mechanism of lignin formation from carbohydrates in wood, and in the overall progress of lignification.

The best pictures of bacterial nuclei, regardless of whether ribonuclease or hydrochloric acid is used for their demonstration, are obtained with very young cultures, still in the lag phase or at the beginning of the logarithmic phase of growth. At this stage the cells are of maximal size; the nuclei, too, are very large but difficult to demonstrate without pre-treatment because the young cells are very rich in ribonucleic acid and hence intensely basophilic. By contrast, the cells of old cultures are far less strongly basophilic and their nuclei can often be stained directly without the help of any pre-treatment, a fact already utilized by Peshkoff[6]. A possible explanation of the changed staining properties of cells from old cultures may be simply the fact that many bacteria contain a very active ribonuclease, but lack appreciable amounts of desoxy-ribonuclease. For example, a ribonuclease from *Bact. coli*, which we have been able to extract and purify, has proved an entirely satisfactory substitute for pancreas ribonuclease in the demonstration of bacterial nuclei. Thus it may well be that in old cultures, where the majority of cells are dead, bacterial ribonuclease has destroyed the greater part of the ribonucleic acid in the dead cells, leaving the nucleus practically intact. However, this effect is not found in all bacteria, and there are great species variations in ribonuclease content. Thus, *B. anthracis* and the staphylococci contain much less ribonuclease than *Bact. coli*.

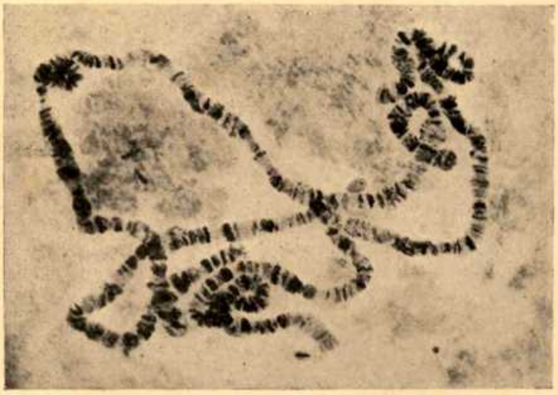
Salivary Gland Chromosomes of *Anopheles*

AN investigation of the salivary gland chromosomes of *Anopheles maculipennis* var. *atroparvus* was begun with the aim of finding out: (1) whether a technique could be produced giving preparations of salivary gland chromosomes, of this and other species, sufficiently detailed for a proper cytological analysis; and (2) if this was possible, whether natural populations exhibit variation in the salivary gland chromosome patterns, and hence comparative karyology might supply an additional tool in the study of geographical, ecological and physiological variation in the genus *Anopheles*.

The first aim was successfully achieved after realizing that a main cause of past failure in obtaining good preparations lay in the conditions (especially nutritional) under which the larvæ were reared. The addition of certain growth factors in the medium proved decisive; the larvæ are now supplied with yeast and *Vorticellæ* in spring water corrected for salinity and *p*H (constant temperature 20–21° C.). The salivary gland chromosome preparations obtained after rearing the larvæ in this way are so clear that a 'map' for *Anopheles maculipennis* var. *atroparvus* has already been drawn. Encouraging results have also been obtained in the second aim, namely, that of variation in the salivary gland chromosome patterns in natural populations. In five instances differences have been found.



PHOTOMICROGRAPH OF SALIVARY GLAND CHROMOSOMES OF *Anopheles maculipennis* VAR. *atroparvus*

Mitotic metaphase plates of *A. maculipennis* var. *atroparvus* show three pairs of chromosomes: two V-shaped and one, the sex chromosomes, rod-shaped. In the females the two rod-shaped chromosomes appear to be connected with two small heterochromatic dots. In the males the heterochromatic dot is smaller in one of the two sex chromosomes, which can therefore be assumed to be the *Y*-chromosome. It is interesting, in this connexion, that Stevens[1] found in *A. punctipennis* four pairs of chromosomes, one of which consisted of heterochromatic material.

The salivary glands of *A. maculipennis* var. *atroparvus* are divided into two lobes. There are about 65 cells in the distal lobe and 21 in the proximal one, the latter giving the best cytological preparations. The salivary gland cells show five chromosome elements connected by a chromocentre. The first of the two V-shaped chromosomes consists of a 'right' arm (II*D*) measuring 96 μ, and a 'left' arm (II*S*) measuring 102 μ; in both arms there are two well-defined zones easily recognizable, besides the two free ends. The second V-shaped chromosome consists of a 'right' arm (III*D*) measuring 116 μ and a 'left' arm (III*S*) measuring 78 μ; there are five easily recognizable zones, two in the III*D* and three in the III*S*, besides the two free ends. The sex chromosome measures 46 μ, and intercalary heterochromatic regions are probably present. This *X*-chromosome appears thicker and better defined in salivary glands of larvæ of females than in larvæ of males. The two heterochromatic dots present in the mitotic chromosomes cannot be identified in the salivary chromosomes.

The five chromosome elements have been carefully mapped, and such maps have made it possible to compare different races of *A. maculipennis*. The analysis of the salivary gland chromosomes of hybrid larvæ derived from crosses between different races could not be carried out during the winter, but is now in progress. Direct comparisons of the salivary gland patterns of *A. maculipennis* var. *atroparvus* with those of the varieties *elutus* and *tipicus* (from Rovigo Province) and *messeæ* (from Pavia Province), all having identical mitotic chromosomes and larval

Detailed accounts of these studies will appear in due course in the *Archives of Biochemistry*.

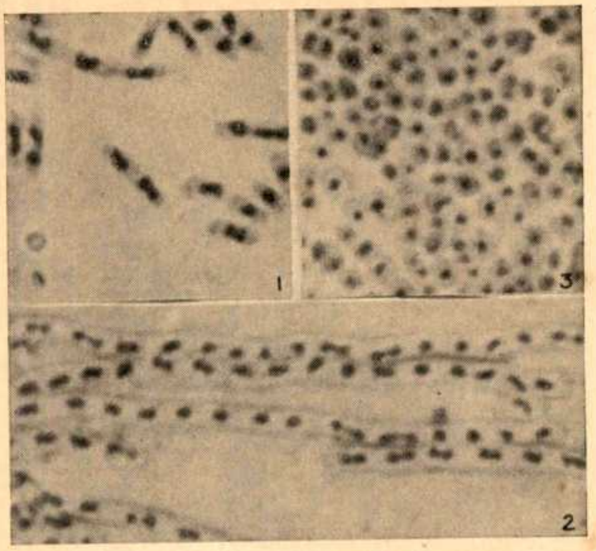
Demonstration of Bacterial Nuclei with Ribonuclease

As part of a general programme of research on the biological significance of nucleic acids in micro-organisms, we have investigated, under the direction of Prof. Boivin, the exact localization of ribo- and desoxyribo-nucleic acid in bacterial cells. Cytological observations of the last decade have furnished convincing evidence of discrete nuclei in many species of bacteria. A method that has been much used to differentiate the nuclear structures from the strongly basophilic cytoplasm consists in treating suitably fixed bacteria with warm hydrochloric acid, followed by staining with Giemsa solution[1]. Using chemical methods on bacteria in bulk, one of us demonstrated[2] that the success of the hydrochloric acid – Giemsa method is due to the fact that ribonucleic acid is removed more rapidly from the cells by hydrochloric acid than the desoxy compound. In view of this result, and of what is known about the distribution of the two types of nucleic acid in the cells of higher organisms, it is plausible to assume that in bacteria, too, ribonucleic acid is located in the cytoplasm, the desoxy acid in the nucleus, and that the high ribonucleic acid content of bacteria (10–15 per cent in cells from the end of the lag phase and the beginning of the logarithmic phase[3]) is responsible for the strongly basophilic character of young bacterial cells and the difficulties encountered in demonstrating their nuclei by conventional staining methods.

We have put this hypothesis to the test by studying the action of ribonuclease on bacteria[4]. By treating fixed bacteria with purified preparations of ribonuclease it is possible to suppress the affinity for basic dyes shown by the bacterial cell as a whole, leaving in its interior a chromophilic body which presents various aspects of constriction and division and is obviously the nucleus already seen by the earlier workers. (More recently, we have found that it is possible to suppress the affinity for basic dyes of not only the cytoplasm but also the nuclei by the successive action of ribo- and desoxy-ribonuclease.) The localization of ribonucleic acid in the bacterial cytoplasm is thus established, and the method gives, in addition, very convincing pictures of bacterial nuclei. The choice of the fixative proved very important in obtaining clear-cut results of enzyme action. Alcohol alone has given us poor results, formalin alone much better ones; in the end we decided in favour of Chabaud's[5] mixture of alcohol 80 per cent (60 ml.), phenol (15 gm.), formalin (5 ml.) and acetic acid (2 ml.), which has given consistently good results with a variety of materials. Osmium tetroxide, excellent as a fixative in connexion with the hydrochloric acid – Giemsa method, cannot be employed for preparations which are to be treated with ribonuclease, since osmium interferes with the action of the enzyme. The ribonuclease which we used was prepared from pancreas with slight modifications of the techniques of Kunitz and Dubos. Heating this preparation to 100° C. removes all traces of the heat-labile desoxy-ribonuclease but leaves the activity of the ribonuclease unimpaired.



NUCLEI IN *Bact. coli* (FIG. 1), *B. anthracis* (FIG. 2 AND *N. gonorrhœæ* (FIG. 3) STAINED WITH GIEMSA SOLUTION AFTER PRE-TREATMENT WITH RIBONUCLEASE. Mag. × *c.* 3,000

To demonstrate nuclei, fixed films of bacteria were treated for several minutes with a 2 per cent solution of ribonuclease at 60° C., rinsed with water, stained with Giemsa solution and examined after drying.

Extraction with ribonuclease has enabled us to demonstrate nuclei in various stages of division very clearly in many different strains of *Bact. coli* (Fig. 1). In agreement with earlier workers we found single, central nuclei in some of the cells, regularly spaced groups and chains of nuclei in others. Very clear pictures of nuclei were also obtained after ribonuclease treatment of vegetative cells of *B. anthracis* (Fig. 2). In *C. diphtheriæ*, of which we examined a strain distinguished by the almost complete absence of metachromatic granulations, we met with a bewildering variety of nuclear configurations. We are now trying to ascertain whether any correlation exists between the different cytological appearances and the growth-cycle of this organism. We have also seen well-defined nuclei in enzyme-treated gonococci in pus and in pure culture preparations (Fig. 3). Pyogenic staphylococci proved very resistant towards ribonuclease and extraction with hydrochloric acid, although the chemical analyses carried out by one of us[2] show that staphylococci contain large amounts of the same ribo- and desoxy-ribonucleic acids that are found in other bacteria. To explain this unexpected result we must perhaps assume that in these organisms there exist special compounds of ribonucleic acid with the proteins of the cytoplasm, and that ribonuclease can only attack the free but not the bound nucleic acid. We are now experimenting with various pre-treatments (alkali, etc.) with the view of preparing resistant organisms for the action of ribonuclease, and have already obtained some encouraging results.

and imaginal characters, show that: (1) *elutus* has two inversions, a small one in the *X*-chromosome and a larger one in the left arm of chromosome III; (2) *tipicus* has a large inversion in the right arm of chromosome III; (3) *messeæ* has a small translocation and a small inversion in the X-chromosome, and a large inversion in the right arm of chromosome III. All these arrangements are homozygous in each variety.

A comparative analysis is at present in progress with *A. bifurcatus*, the mitotic chromosomes (two V-shaped and one dot) of which differ from those of *maculipennis*. In the gangliar cells and in the resting stage of the germ cells of *bifurcatus* the heterochromatin is almost lacking. The salivary chromosomes of *bifurcatus* are different from those of *maculipennis*, though some similarity of pattern can be recognized in certain regions near the tips. It seems possible that the total or partial sterility of the inter-racial hybrids within the *maculipennis* species is correlated with the chromosomal rearrangements described here, and that the *bifurcatus* salivary chromosome pattern is derived from one similar to that now represented in *maculipennis*.

Histamine as a Physiological Activator of the Reticulo-Endothelial System

MY investigations since 1940 have led to the conclusion that histamine plays the decisive part in the phenomenon of phagocytosis. My experimental work has shown that histamine is able to transform resting endothelial cells into active phagocytes. It is histamine which, as the physiological activator, induces phagocytic activity of the whole reticulo-endothelial system.

If, for example, a histamine solution is painted on the skin of rats and Indian ink then injected into their blood, the smeared areas show grey spots; one can indeed 'write' with histamine on the skin. Through its influence the endothelial cells, especially in the small veins, are transformed to phagocytes and adsorb and accumulate the Indian ink just as reticulo-endothelial cells do. Injected histamine has a general 'activating' effect, for example, in mice, rats and guinea pigs, changing the endothelium of the small veins in all the striated muscles and in the wall of the duodenum into reticulo-endothelium.

This effect of histamine on the endothelial cells can be inhibited by: (1) increasing the tolerance of the animals to histamine, which in mice and rats is easily accomplished by daily repeated histamine injections (rising to 5–10 mgm. subcutaneous doses); (2) preliminary treatment with an anti-histamine agent, for example, Meier and Bucher's antistine[1] (2-(N-phenyl-N-benzyl-aminomethyl)-imidazolin), the specific effect of which is histamine-antagonism.

My experiments with this anti-histamine substance prove that the same characteristic activating effect of histamine keeps the actual reticulo-endothelial system in continuous activity. In the living animal the antistine vigorously curbs, or even stops, the phagocytic activity of the reticulo-endothelial cells. I have demonstrated the inhibiting effect by a new method, worked out with L. Szalay, for the continuous quantitative determination of the activity of the macrophage system.

We injected mice and rats intravenously with Indian ink stabilized with gelatine, which circulates in the blood without a decrease in dispersion as long as the phagocytes accumulate it quantitatively. From a cut at the end of the tail we took 2–3 drops of blood every five minutes, absorbing it on filter paper so that it formed spots about 1 cm. in diameter. After drying, these pieces of filter paper were immersed in slightly alkaline water, in which the blood pigment dissolves, while the Indian ink remains adsorbed in the tissue of the paper. Thus we get a series of gradually paler black-grey homogeneous spots which clearly show the progressive elimination of the Indian ink. We determined the darkness of the Indian ink spots by objective photometric determination of the light reflected by the spot on to a rubidium photocell and measuring the photocurrent by means of a string electrometer. Thus we can calculate the percentage of the light reflected by the clean paper absorbed by the stained spots, and these numerical values represent precisely the process of Indian ink elimination. From data from animals pretreated with large doses of antistine, it appeared that the anti-histamine vigorously hindered, indeed temporarily almost entirely stopped, the Indian ink phagocytosis and greatly extended the elimination time.

That the cause of this inhibition by antistine is really a competitive antagonism between histamine and antistine in the reticulo-endothelial cells themselves was proved by experiments on surviving rat-livers, through which colloidal gold or Indian ink was perfused in 38° C. in Ringer–Locke solution containing 6 per cent human blood serum. While in the control experiments the Kupffer cells filled up in 50 minutes with the accumulated colloid, the antistine in 1 : 2,500 concentration so completely paralysed the phagocytes that they remained empty. The simultaneous addition of histamine to the same concentration, however, overcomes the antistine-inhibition and restores the Kupffer cells to their normal activity. I interpret these experiments as meaning that the two compounds of related structure compete on a mass action basis for one and the same receptor of the mesenchyme cell, the receptor to which histamine has to be bound to produce the phagocytic function. The reticulo-endothelial cells work under the constant influence of histamine, the place of origin of which is unknown.

My investigations indicate that, as the actual agent of phagocytosis, histamine—that is, its liberation—has a central role in the defensive and recuperative reactions of the organism. Its role in inflammation is primarily explained by its phagocyte-activating effect. The liberation of the latent histamine in the tissues through different physical and chemical influences is a purposeful process: in consequence of its effect the place of the lesion is immediately surrounded by an active reticulo-endothelial zone. Mechanical injury or substances causing inflammation, for example, allylisothiocyanate, also change the endothelium of the vessels into reticulo-endothelium. These indirect activating effects can also be inhibited by desensibilizing histamine treatment or by a previous antistine injection.

A detailed description of these investigations will be published elsewhere.

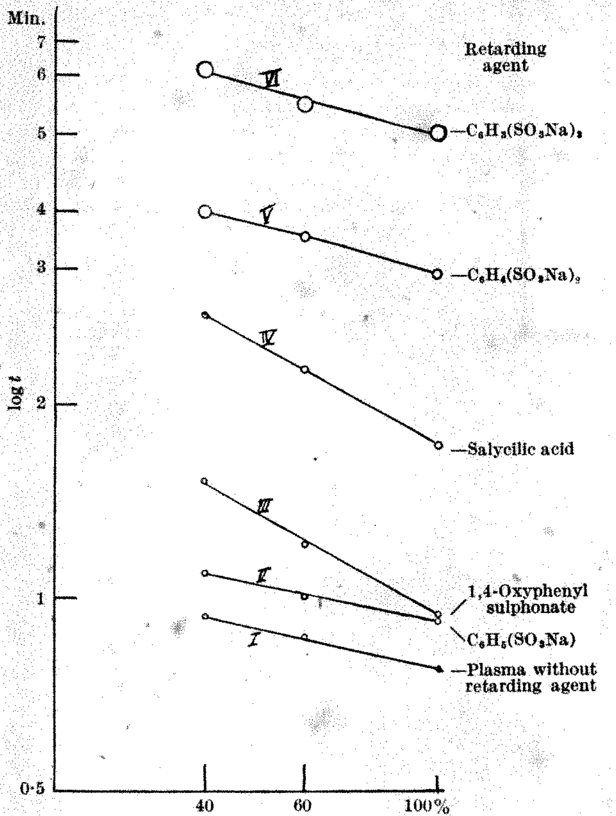
Influence of Hydrotropic Substances on the Sol/Gel Transformation of Blood Plasma *in vitro*

JORPES[1], studying the chemistry of heparin, and, before him, Demole[2] and Fischer[3], have insisted upon the importance of the —SO_3H group for the inhibition of blood-clotting. Link *et al.*[4] have proved that salycilates have an antiprothrombinæmic effect, which is about twenty times weaker than the equivalent dose of 'Dicumarol' (Quick[5], McKennie[6]). In order to get comparable data between the retarding influence on blood-clotting and the chemical constitution, we have measured the effect of the following hydrotropic substances *in vitro*: the sodium salts of phenyl-sulphonic acid, 1,4-oxy-phenyl-sulphonic acid, salycilic acid, 1,3-phenyl-disulphonic acid, 1,3,5-phenyl-trisulphonic acid. The method consists in mixing in small test-tubes 0·1 ml. of normal oxalated blood-plasma (human) with 0·1 ml. of a mixture of phosphate buffer and hydrotropic substance, and 0·2 ml. 'Thromboplastin' (Hoffmann-LaRoche, Basle). The phosphate buffer consists of $M/30$ potassium dihydrogen phosphate and disodium hydrogen phosphate, so as to give a pH of 7·2. It contains, further, sufficient hydrotropic substance to make it one third molar.

Series of four test-tubes containing analogous mixtures are placed in a water-bath at 30° C. After two minutes 0·2 ml. of $M/40$ calcium chloride are added (time 0) and carefully mixed. Thus the volume of the final mixture is 0·6 ml. and the concentration of the retarding substance therein is $M/18$. The four test-tubes are then mechanically waved (not shaken) in the thermostat at 30° C., up to the time when the solution moves no longer as a liquid but becomes a firm gel. The moment when the sol/gel transformation is complete is sharply defined and takes place within 3–4 sec. for all the four test-tubes. In order to test the reproducibility, we have repeated the four-tube series three times. We found a variation of times within $\pm$ 1·5 sec. so long as the sol/gel transformation takes place in less than 2 min., and $\pm$ 2·5 sec. when the process takes longer. Besides the times for undiluted plasma we have also measured plasma-dilutions with saline of 60, 50 and 40 per cent. If we plot the logarithmic values of these dilutions (c) against the logarithmic values of the times (t) measured, the results give a straight line, the equation of which is

$$t = k \times c^{-a} \text{ (compare Legler}^{7}\text{).}$$

The lowest line (I) is obtained without addition of a retarding substance. If we compare the time gained with undiluted plasma with the times retarded by addition of $C_6H_5SO_3Na$ (II), $C_6H_4\,(SO_3Na)_2$ (V) and $C_6H_3\,(SO_3Na)_3$ (VI), we find a proportion of 1 : 1·23 : 4·37 : 7·56. The retarding effect of two SO_3Na-groups instead of one is, therefore, 3·14, and the effect of three such groups instead of two is 3·19. The three sulphonates which were tested have a different parameter k but the same exponential factor a, as their lines have the same angle with the base line. It is noteworthy that both the lines of 1,4-oxyphenyl-sulphonate (III) and of salycilic acid (IV) have a different k and a from the three sulphonated products. The retarding effect of the five hydrotropic substances which were evaluated increases in the same order as the substances as listed above. Our results are a new proof that the more SO_3Na-groups are present in the molecule of an aromatic substance the more efficient they become in retarding the clotting process of blood plasma *in vitro*. Their action, insignificant *in vivo*, is ascribed to the very small molecular weight, compared with those of heparin and the different synthetic polysulphuric acid esters. Therefore, their concentration in the blood-stream is diminishing too rapidly.



TIME OF PLASMA SOL/GEL TRANSFORMATION

The radius of the circles gives the precision with which the time of the plasma sol/gel transformation can be reproduced. With increased prolongation of the clotting process, the reproducibility tends to become less exact

The measurement of the sol/gel transformation time with 1,4-oxyphenylsulphonate as a retarding agent is of such precision that we have founded upon it a routine procedure for the clinical laboratory. Details of results are in the press and will be published elsewhere.

Cushion Cells in Retinal Pre-capillaries and Capillaries

I HAVE observed large cells of the intimal layer of retinal arterioles, capillaries and venules situated mostly at vessel branches. These cells reduce the lumen to a narrow slit or occlude it completely. The protoplasm of these cells is granular and gives them an appearance different from that of the other intimal cells. These cushion cells are best visible unstained in glycerine-cleared retina with reduced illumination.

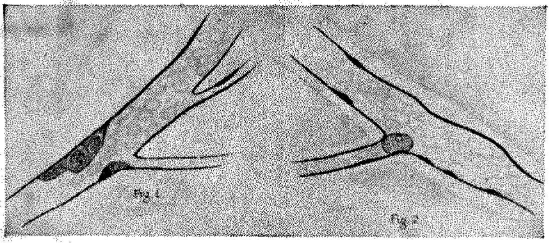

Fig. 1. CUSHION CELLS IN A RETINAL VENULE. UNSTAINED. × 225

Fig. 2. CUSHION CELL IN AN ARTERIAL BRANCH. UNSTAINED. × 225 RETINA IN BULK, CLEARED

They have been stained with azo-eosin in bulk. I was unable to discover them in stained paraffin sections. The dehydrating process seems to cause a shrinkage, which makes the cushion cells indistinguishable from other intimal cells. It is probable that these cushion cells regulate the retinal blood stream within the fine branches according to need.

Unusual Flame Gases

HYDROGEN–AIR mixtures containing less than about 20 per cent hydrogen when burnt at an orifice undergo two highly contrasted modes of combustion which result in flame gases of very different types. In our experiments well-mixed mixtures of hydrogen and air contained in a tank were supplied to a burner in the form of a long narrow slit, the width of which was 1/16 in. The temperatures attained by very fine platinum–rhodium wires (0·0005 in. diameter) and by quartz-covered platinum wires (0·0005 in. overall diameter) were measured at some two hundred points in the flame gases. A contour map of the platinum wire temperatures in the lower portion of the flame gases resulting from the combustion of a 14 per cent mixture is shown in Fig. 1. These results are summarized in Fig. 2 and extended to a flame height twice that shown in Fig. 1. The temperatures measured by the quartz wire were almost exactly the same as those measured by the platinum wire, except in the early stages after combustion at the sides of the combustion zone (see dotted curves, Fig. 2).

From Fig. 2 it will be seen that after a prolonged interval (which decreases as the mixture strength is increased) the wire temperature attains a steady value, indicating that the flame gases have attained a state of equilibrium. The steady temperature is some 130° C. below the calculated temperature (1,140° C.), and, as the radiation losses are known to be small, this suggests that the flame gases in this state contain in very stable fashion an unreleased energy[1,2] amounting to at least 10 per cent of the heat of combustion.

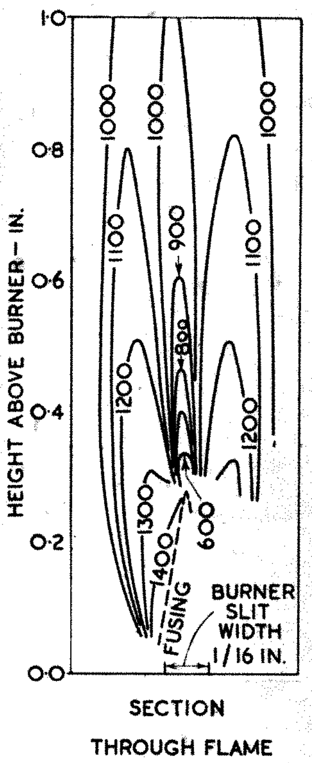

Fig. 1

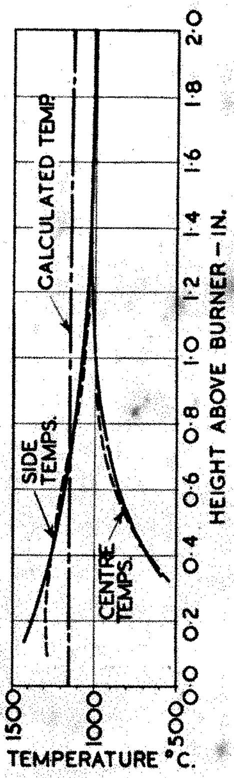

Fig. 2

But we wish to direct attention especially to the state of the flame gases during the interval before the attainment of equilibrium. First take the central gases. It will be seen that immediately above the peak of the combustion zone the temperature measured by both the platinum and the quartz wires is less than 600° C. (which is more than 500° C. below the calculated temperature). This temperature gradually increases until the steady temperature of 1010° C. is reached. Flame photographs show that little, if any, luminosity (or ultra-violet radiation) is emitted by these gases, or indeed by the peak portion of the combustion zone from which they emerge. (We could only infer the position of the peak portion by the fusing of the platinum wire, as a result of surface combustion, as it was brought down into the unburnt gaseous mixture—see dotted curve, Fig. 1.) It seems possible that the cause of this curious type of combustion is a pre-treatment of the unburnt mixture during its travel upwards between the two intense side combustion zones (see below). The low temperature of the flame gases does not seem to be due to the formation of hydrogen peroxide, and we suggest tentatively that it may be due to temporary linkages of water molecules (as in the case of superheated steam near the saturation temperature).

In the case of the side flame gases, the platinum wire temperature is as much as 200° C. greater than the calculated temperature, and, very surprisingly, the temperature attained by the quartz wire is just as great—except in the very early stages after combustion. These gases and the intense side combustion zones are readily photographed. If it may be assumed that atomic oxygen, unlike atomic hydrogen, combines equally efficiently on quartz as on platinum, it would seem clear that large quantities of atomic hydrogen are present in the flame gases as they leave the combustion zone, and that these react with oxygen to form atomic oxygen ($H + O_2 = OH + O$). Accepting this hypothesis, other experiments indicate that this reaction proceeds more slowly in flame gases at lower temperatures and more rapidly in flame gases at higher temperatures.

It is of interest to add that the wire temperature map is completely changed when some of the hydrogen in the hydrogen – air mixtures is replaced by carbon monoxide, and also when hydrogen is substituted for the excess oxygen present in the hydrogen – air mixture.

Second-Order Raman Spectra of Crystals

USING the smaller Hilger quartz spectrograph and the λ 2536·5 radiations of the mercury arc as exciter, tests were made to determine the minimum exposure times required to bring out the various features observed in a fully exposed Raman spectrum of diamond. The line with a frequency shift of 1332 cm.$^{-1}$ appeared on the plate with an exposure of only five seconds. Half a minute was needed to record the Brillouin doublet centred about the exciting radiation, the latter itself being filtered out by a mercury vapour screen. An exposure of half an hour sufficed to record the second-order Raman spectrum, while the anti-Stokes frequency shift of 1332 cm.$^{-1}$ appeared after forty-five minutes. An exposure of three hours results in heavily over-exposing the second-order Raman spectrum, but is useful in bringing out clearly the weak terminal line having a frequency shift 2015 cm.$^{-1}$, which is liable to be overlooked with smaller exposures. (This line and its more intense neighbour at 2176 cm.$^{-1}$ are of special interest as they appear with great intensity in the infra-red absorption spectrum of diamond.) Longer exposures up to ten hours reveal no new features. It is very significant that no hint or trace of the continuous spectrum of elastic vibrations forming the so-called 'acoustic branches' of the lattice spectrum of the crystal appears on the plate even with the longest exposures. This will be evident from a comparison of Fig. 1 (*a*) and 1 (*b*), the former being the spectrum of the mercury arc and the latter the spectrum of diamond recorded with six hours exposure.

The great disparity of behaviour which these observations disclose between the parts of the vibration spectrum in the upper and lower ranges of frequency is intelligible only when we recognize the fundamental difference in their nature. The acoustic spectrum has its origin in the propagation of elastic waves through the crystal from end to end, while the infra-red vibrations are evidently not 'waves' but eigen-vibrations of the individual units of the crystal structure. The experimental facts recorded here, and the discrete line structure of the second-order spectrum illustrated in an earlier communication[1]) (see also the accompanying photomicrometer record (Fig. 2)), are in my opinion conclusive evidence of the correctness of the theory of the vibration spectra of crystals put forward by Sir C. V. Raman[2].

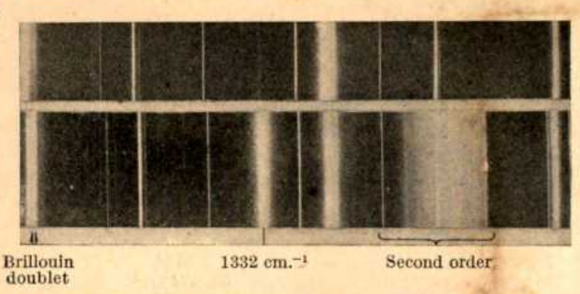

Fig. 1. ABOVE, FILTERED MERCURY SPECTRUM; BELOW, HEAVILY EXPOSED RAMAN SPECTRUM OF DIAMOND

The alkali halides are much less suitable than diamond as material for investigations in this field, for their vibration frequencies are much lower and are also broadened out by thermal agitation; by reason of the ionic nature of the crystal, they also appear much more feebly in the second-order Raman effect. Hence the difficulty of obtaining adequately exposed and well-resolved spectrograms free from the effects of false illumination is far greater. Nevertheless, the results I have obtained with rock-salt[3] are clear enough and should convince those with practical experience of spectroscopic research in this field. The experimental difficulties in recording satisfactory results are even greater in the case of potassium chloride and potassium bromide than in the case of rock-salt, since the vibration frequencies are still lower. A comparison of the spectrogram of potassium chloride I have obtained[4] with that reproduced in a recent note in *Nature*[5] indicates that

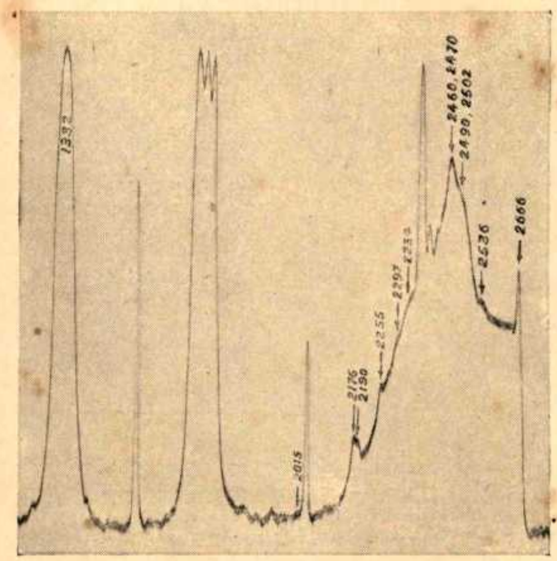

Fig. 2. PHOTOMICROMETRIC RECORD OF THE RAMAN SPECTRUM OF DIAMOND TAKEN WITH MEDIUM-SIZE SPECTROGRAPH

the latter has been vitiated by parasitic illumination in the spectrograph.

Adsorption Isotherm of a Photographic Emulsion for Uranyl and Lead Ions

RADIOACTIVE track count methods with photographic plates can be applied to the determination of nuclear reaction cross-sections, of nuclear particle fluxes, of decay constants and of small concentrations of certain elements[1]. The reactive nuclei can be introduced into the emulsion by the 'drop method', in which a drop of a suitable solution is spread on the surface of the emulsion, and left to penetrate into it, and to dry. This method uses the full quantity of the nuclei contained in the drop; however, the penetration into the emulsion is not uniform, so that an average track count must be derived from a survey of the whole area covered by the drop, or of a representative section of this area. In the alternative 'immersion method', the plate is left to imbibe the material from a solution in which the plate is totally immersed. Thus, the distribution of the dissolved substance over the emulsion must be uniform at least in the horizontal plane, but the fraction of the solute taken up by the emulsion depends on conditions and must be determined specially by conventional analytical or by radioactive methods. The uptake of uranium by Ilford Concentrated Half-Tone Plates and its dependence on time of immersion, conditions of rinsing after immersion, concentration of uranyl ion, pH and presence of other salts has been examined[1]. It seems desirable now to report the results of tests where the concentration was varied more widely, and where besides uranyl ions lead ions were employed.

The Ilford plates were handled as before[1], but the area of each field of view under the microscope was now only about 7×10^{-5} cm.^{2}. In Fig. 1 the uptake of uranium by the emulsion is plotted against time of immersion (in minutes) for four solutions of uranium in 5 per cent (by volume) acetic acid. The ordinates give the track counts (T) per field of view and 24 hours exposure, and are multiplied by factors of 1, 12, 40 and 60. The rate of uptake decreases rapidly with time, and the shape of the curves at all concentrations is similar. In Fig. 2 (based on more experiments than Fig. 1) the track count per 24 hours exposure following immersion of standard duration (1,000 min.) is shown (logarithmically, for clarity) as a function of the concentration c. In spite of the lack of saturation and the blocking of part of the volume of the emulsion by silver salt, the absolute values of the uptake exceed the values calculated from the volume of the (dry) emulsion; for example, the track counts of the $1{\cdot}2 \times 10^{-1}$ and the $5{\cdot}5 \times 10^{-5}$ M solutions would correspond to $1{\cdot}1 \times 10^{-10}$ and of $3{\cdot}5 \times 10^{-13}$ gram-atoms of uranium, respectively, in the cylindrical volume defined by one field of view (7×10^{-5} cm.^{2} area and the depth due to the thickness of the emulsion before fixing, namely, 2×10^{-3} cm.), and hence to concentrations in the emulsion of $0{\cdot}78$ and $2{\cdot}5 \times 10^{-3}$ M; these concentrations are larger than those in the solutions by factors of 6·5 and 45. The excess must be explained mainly through adsorption; the temporary expansion of the emulsion during impregnation through swelling is insufficient. Therefore, the uptake function of uranium (Fig. 2) can be described as an 'adsorption isotherm'. At saturation the adsorption isotherm will be of similar shape, as the ratio of the uptakes with different concentrations at 1,000 min. can scarcely differ from that at saturation (cf. Fig. 1). The uranium isotherm in Fig. 2 is well represented by a linear equation

$$\log T = \log A + f \log c,$$

with A as a numerical constant, and can be rewritten in the familiar form

$$T = Ac^f.$$

The exponent f has the value 0·80.

In tests with uranium the concentration cannot be decreased beyond certain limits if unreasonably long times of exposure are to be avoided. To cover a more extensive range of concentration some tests were carried out with the lead isotope thorium B, which can be diluted with inactive lead at will. In this way the radioactivity per unit volume of solution was kept constant, while the total concentration of

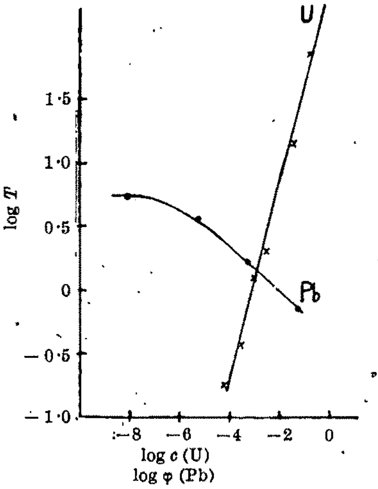

Fig. 2

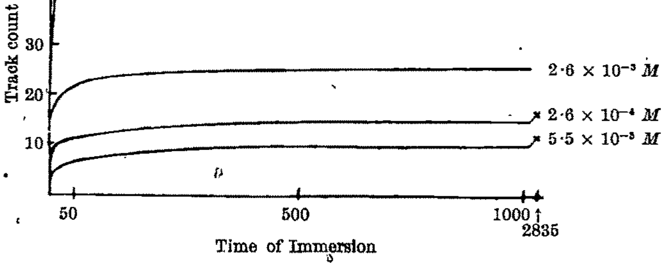

Fig. 1

lead was changed. Thorium B itself emits only β-rays, which are not registered by the plate, but every disintegration is followed quickly by α-decay of either thorium C or C′, so that the total track count (thorium C and C′ tracks combined) still gives the number of decayed thorium B nuclei. Four thorium B solutions (of the order of 10^{-2} micro-curies/c.c.) in 5 per cent acetic acid were used, in which the total concentrations of lead were made $5{\cdot}3 \times 10^{-2}$, $5{\cdot}3 \times 10^{-4}$, $5{\cdot}3 \times 10^{-6}$ and $6{\cdot}8 \times 10^{-9}$ molar. The time of immersion was 30 min. In Fig. 2 the logarithm of the track count is plotted against the logarithm of the concentration (φ) of inactive lead. Here, in the evaluation of the adsorption isotherm from the graph, the 'invisible' adsorption of inactive lead must be taken account of by replacing T and c by f_cT and φ.[1] The concentration c of the radio-lead remains constant. At the higher concentrations the results fit again a straight line. Hence

$$\log T = \log B + g \log \varphi,$$

that is,

$$(f_cT) = B'\varphi^{g+1} = B'\varphi^{f}.$$

In the linear portion the value of f is 0·83, but at concentrations below about 10^{-6} the uptake increases more rapidly with concentration.

It will be interesting to compare by this sensitive method the adsorbability in standard conditions of chemically different α-active isotopes down to very small concentrations. From a practical point of view the knowledge of the adsorption isotherms will assist in the assay by track count methods of traces of α-ray emitters.

Mercury Tube Effect

By anodic polarization of the dropping mercury electrode, the drops have been made to form at the end of an apparent 'mercury tube or thread', namely, a semi-solid tube or thread of mercury, or a mercury compound, suspended from the capillary tube.

The dropping mercury electrode was polarized from the mains with the aid of a potential divider. A platinum electrode functioned as an anode, both for the dropping mercury electrode and in a supplementary circuit containing a 2-volt accumulator for the cathodic polarization of a layer of mercury at the bottom of the cell (used in the purification of the solution by pre-polarization). The dropping mercury electrode was first polarized cathodically at a current-strength of 10^{-1} amp. At this current bubbles were generated at the end of the tip and dropping ceased. The applied potential was now decreased to zero, thus connecting the dropping mercury electrode with the platinum anode and anodically polarizing it with respect to the cathodic mercury pool at the bottom of the cell. A few seconds after the commencement of anodic polarization, darkened drops appeared, which, upon falling from the capillary, left behind them a black tube. After the formation of the tube, the drops grew at its end and fell therefrom, largely as if from the capillary. In some experiments, after an indefinite time from the commencement of formation of the tube, a sudden extension in its length took place; this seemed to occur when the drop size was at its maximum. The potential of the dropping mercury electrode was about + 1·7 volts on the hydrogen scale at the commencement of the phenomenon, and seemed generally to fall to a potential between about + 0·8 and + 1·3 volts when the phenomenon ceased.

The black thread was collected in a cup operated from outside the cell. The collected substance appeared to decompose rapidly to mercury when removed from the solution, thus making its analysis difficult.

It seems probable that the anodic evolution of chlorine at the electrode in the above experiment forms a thin film of a chloride of mercury and that it is an elongated skin of this which forms the tube. It is possible that the sudden increase in length of the tube sometimes observed is due to the completion of a layer of a different chloride formed during the continued anodic polarization.

An investigation of the phenomenon is in progress.

Spiral Cracks in Glass Tubing

To the examples cited by Dr. J. J. Hopfield and Messrs. B. N. Clack and N. L. Harris on this subject,[1] I should like to add a further rather unusual example. This was in $X8$ soda-glass tubing of 6–7 mm. diameter and 0·15–0·25 mm. wall-thickness. Large quantities of this tubing were being handled, and frequently, when it was being cut into lengths, a spiral or rather helical crack would fly along the piece. The cracks were of 5–7 mm. pitch, and produced springy lengths of up to 12 in.

With such a thin wall the strain 'through the wall', which caused such cracks as those previously cited, would scarcely at first sight be expected. However, the tubing was being produced by machine-drawing at a very high rate, some 1,000 ft. per minute, so that the rush through the air and the resulting rapid cooling of the outer skin, while the inner was kept hot by the hot air-blast through the mandrel, could very well have produced this strain. In the very thin section this strain was naturally difficult to detect.

BRITISH IRON AND STEEL RESEARCH ASSOCIATION

THE manifold demands made by a live industry on its research association are well illustrated by some of the current activities of the British Iron and Steel Research Association. Co-operative research lends itself readily to organised investigation into the background problems of industrial processes. Sometimes these are indicated by the failure of an unproved technique; sometimes by new demands on the part of the user which call for extension of knowledge and technique on the part of the supplying industry; but most often the process is dictated by the natural desire of the industry concerned to improve its processes, qualities and general economy.

An example of investigations stimulated by the failure of a technique insufficiently understood is the work which has been done on brittle fracture in mild steel plates. The welding in certain ships made in foreign countries during the War failed, and representatives of all British organisations interested—governmental and Service departments, other research associations, the universities, Lloyd's and numerous industrial laboratories—carried out various investigations culminating in a conference in October 1945. As a result of intensive discussion under the chairmanship of Dr. (now Sir Andrew) McCance, who is chairman of the council of the British Iron and Steel Research Association, the lines of research necessary for ascertaining the cause and cure of the phenomenon of brittle fracture were indicated.

Subsequent researches at the works of Colvilles Ltd., and at the University of Cambridge, established that brittle fracture was related to manganese content, plate thickness and the rate of cooling, the effect of the first factor being by far the greatest. Further work at Colvilles on small, closely controlled casts of steel made by the high-frequency process has now established that for a given tensile strength an increase in the manganese – carbon ratio of mild steel has the desired effect of lowering the temperature range below which one must go before brittle fracture may take place. This effect is related to the fact that the increased ratio also tends to give a fine-grain steel. The latest work on this subject is able to conclude with a practical recommendation that for shipbuilding steels the manganese – carbon ratio should not be less than 3·0.

The results to date of this extensive series of experiments have been distributed to the members of the Association and participants in the original conference, and are shortly to be made available to a wider public through the technical press.

Another project also bears on embrittlement, but in this case at high temperatures. The brittle constituent (sigma phase) of the iron – chromium and the iron–chromium–nickel systems is being studied at the National Physical Laboratory for the Association, as the appearance of this constituent during service at elevated temperatures can cause serious embrittlement in certain commercial alloys. Limits in composition to avoid the appearance of the sigma phase are now being defined for pure ternary alloys, and eventually the effect of other elements upon the systems will be investigated. A related and rather more extensive research deals with the influence of alloying elements on the properties of ferrite.

These latter projects may be taken as examples of investigations with the object of meeting new demands, in this case made by the designers of gas turbines and other high-duty engines. The successes met with by the works laboratories, working in competition, are well known, and may be said to be approaching their limits within the bounds of the available 'background' knowledge. It is the natural task of the research association to organise the pooling of information to the necessary extent, and to widen our background knowledge, thus enabling the industrial laboratories to proceed once more in healthy rivalry. This is a continuing process, which an alert industry will demand of its research association without intermission.

The great bulk of the work of the British Iron and Steel Research Association, however, originates from the discussions of the voluntary panels and committees which supervise and canalize the Association's activities. These committees are widely drawn from the iron and steel industry, the universities of Great Britain, Government research laboratories, steel users, etc. They are kept small, the total membership numbering about 450 for nearly sixty committees. The Association's work is organised in six divisions, corresponding to the main divisions in the industry, each being controlled on a largely decentralized basis by a panel. There are also three, so to speak, 'horizontal' departments (physics, chemistry and engineering) which carry out more fundamental work and work common to a number of divisions, and incidentally play a useful part in maintaining liaison between the six divisions.

Some three hundred projects are in hand, covering the industry's production cycle from the blast furnace and its raw materials to the rolling mill, draw-bench and final application. These projects range from the severely practical to the 'purely' theoretical.

The modern blast furnace is highly efficient from a thermal point of view. Improvement is sought, however, in output, smooth working, high-grade production, requirements of special coke and in general operational economy. A considerable volume of work goes on in attempts to determine the best conditions and proportions of the constituents of the burden, the best methods of distribution and the extent of heat and gas penetration into various types and sizes of ore. Consideration is also being given to the use of gas turbines for blowing. The Association has an experimental blast furnace with a 1 ft. 9 in. hearth at Stoke-on-Trent where much of this work is carried out. This 'baby' is believed to be the smallest working blast furnace in existence.

At Stoke-on-Trent the Association has in addition a model open-hearth furnace, which for the last two years has afforded information of great importance on the design and operation of such furnaces. Also at the steel-making stage the factors affecting sulphur removal are being studied both in the plant and in the laboratory. Most of the latter work is done at the universities. The subjects of instrumentation and heat measurement receive their share of attention, and the new problems raised in the extensive programme of converting open-hearth furnaces to oil firing lend particular importance to these investigations. The Physics Department has constructed a black-body furnace with a 3-in. aperture for calibrating pyrometers up to 1,700° C., and is also investigating problems in connexion with quick immersion thermocouples.

It is part of the task of the Chemistry Department to work in close collaboration with the British Refractories Research Association, and one of the big problems in this field is at present the development of the all-basic open-hearth furnace. This should have many advantages over the normal type with a silica roof, and its higher operating temperature should result in increased output.

In the field of steel castings, a thorough investigation is being made into foundry moulding materials and the fundamental mechanism whereby they are bonded together. The allied problems of hot tearing and the rate and direction of heat abstraction on solidification are being examined, as also are methods of controlling the melting process by spectroscopic inspection of the flame of Tropenas converters during steel-melting.

Work going forward nearer the finishing end of the industry includes research on coating, rolling and drawing. At the Association's new laboratories in South Wales (see *Nature*, July 19, p. 100), work goes on concerned with the distribution, thickness and porosity of tin, zinc and non-metallic coatings, and with further projects on the geometrical characteristics of metal surfaces.

In the investigations into drawing problems, the Physics Department has assisted in devising an instrument for measuring the tension in wire as it is drawn, the variations in oscillation under varying tensions being used for this purpose. Theoretical and practical work on plastic deformation in rolling goes forward at the Universities of Cambridge and Sheffield.

The engineering problems that face the iron and steel industry are sometimes insufficiently regarded as being suitable objects of scientific approach. Here the Association's Plant Engineering Division has a wide field, and has done much useful work in organising conferences and other means of exchanging knowledge—a function of immediate importance in the industry's modernization plans. This Division also methodically studies steel-works transport, design and operation problems, and is responsible for a wide range of research on fuel problems.

This very brief summary suffices to show the immensely wide field an industrial research association has to cover. The work ranges from the most 'purely' theoretical study of the thermodynamic and chemical aspects of the steel-making process, to the most severely practical investigation into engineering problems. All this is comprehended in the mutual aim of science and industry to ensure that the methods and discoveries of the one shall be with the least delay at the service of the other.

BOTANY OF THE WILD AND CULTIVATED RICES

By Dr. D. CHATTERJEE

The Herbarium, Royal Botanic Gardens, Kew

ALTHOUGH much work has been done on the widely cultivated species of rice (*Oryza sativa* Linn.) for its improvement as an agricultural crop, it must be admitted that our knowledge of its morphology and taxonomy and its relationship to other wild species of the genus is comparatively meagre. The term 'wild rice' as employed here is used to indicate all other species which conform by their technical characters to the generic definition of *Oryza*, and which grow spontaneously in a wild state. The two cultivated species are the well-known *Oryza sativa* Linn. and the less known *Oryza glaberrima* Steud. (cultivated in west tropical Africa). In tropical countries where these species are extensively cultivated, it is unfortunate that a comprehensive account of the rice plant with a proper interpretation of all the structures, its evolution and domestication by man is not generally given in text-books on botany and tropical agriculture. This omission makes its study uninteresting and often vague. The aim of this note is to put together some of these much-needed data with a suitable list for further reference.

Domestication of 'Wild Rice' by Man

The history of cultivated rice goes so far back into the distant past that it could be associated with the early history of man. It has been said that man has passed through three successive stages of civilization, that is, the hunting, pastoral, and agricultural. In the early stage men hunted in packs the wild animals of the grassland. The women also hunted with the men and equally shared the products of the chase. The cares of maternity and increased attachment to their homes often made it necessary for the women to drop out from the band for a time. Gradually women found it necessary to supplement their diet with nuts, berries and grains of grasses at times when the food supplies brought by their men-folk ran out. Homes were established near the seashore and banks of lakes and rivers. Fishes and molluscs were also gathered from these sources to supplement the food. Domestication of cattle began at this stage of pastoral life. The idea of growing grains of wild grasses by actual cultivation of land came later, and the exact circumstances are not known but are subject to various speculations.

Recent discoveries in India at Mohenjo-daro in Sind and at Harappa in the Punjab have shown that civilization entered the country as early as 3000–2500 B.C. It appears that the people who came to the Indus Valley at that time from the west had a knowledge of wheat cultivation and they readily adopted the wild rice which they found in that part of India. There is also reason for believing that the people of Mohenjo-daro had trade relations with the Sumerian cities of Mesopotamia, and both wheat and rice might have constituted the articles for trade. Between 400–300 B.C. rice was cultivated beyond the western limits of India and later it was grown in Babylonia, Bacterina and lower Syria. During the early period of the Christian era cultivation was started in Persia and Egypt. In China and Indo-China rice was in cultivation for a long time and no definite account is available how these countries received the art of rice cultivation from the Indus Valley. A possible suggestion is by way of the Hindu Kush, Tibet and Mongolia. The cultivation has spread to Malaysia, Africa and America in recent years. Knowledge of rice cultivation came to south-eastern Europe through the Arabs, who also introduced its cultivation in Spain after their conquest of that country.

The wild rice of India, which may be regarded as the ancestor of the cultivated rice, is found throughout India, Burma and Malaysia. It resembles the ordinary cultivated rice very much but has deciduous spikelets, 3–10 cm. long awns, and a dark red spot between the apex of the *lemma* and the awn. Having taken this plant into domestication, early man, consciously or unconsciously, effected a general trend of improvement by selecting those plants which possessed certain desirable and stable characteristics. These might have been: (1) tufted growth and production of tillers, (2) a height of 3–4 ft., (3) suitability of living in still and shallow water, (4) production at the end of about six months of starchy grains which are not shed, and (5) when the husked grains are boiled they give a pleasant appearance and do not adhere to each other. From this theoretical line, it must be admitted that variations due to mutation and hybridization must have taken place which have given rise to the several hundreds of forms and varieties. The main important change, introduced by domestication, to the wild rice, is the loss of its power to shed the mature spikelets. The power to shed the mature grains is an essential character connected with the dispersal of the seed and ensuring the continuity of the species in all wild plants. This loss of power to shed grains has indeed been a gain on the part of the cultivator; he can now get all the spikelets for the use of mankind from his crop without the fear of losing a large quantity on the field.

Botanists like Chevalier[1] and Backer[2] have considered that the name of this wild rice should be *Oryza fatua* Koen. This name was also followed by Burkill[3] in his discussion of the origin of the cultivated rice. Unfortunately, for technical reasons this name could not be accepted, as this was not validly published with a suitable specific description (*Mem. Acad. Sc. Petersb.*, Ser. 6, 5, pt. 2, 177; 1840). The same plant was described by Prain[4] under the name *Oryza sativa* Linn. var. *fatua* Prain, and this name may be provisionally retained to designate the wild rice of south-east Asia. It is preferable that the wild rice should be separated specifically from the cultivated species of *O. sativa* Linn., since this will be more convenient from the point of view of agricultural workers and other practical considerations. The varietal name given by Prain has to be given up when the specific name of this wild rice is determined by a monographer of the genus. The choice will probably depend on one of the three names *O. montana* Lour. (1790), *O. aristata* Blanco (1837), and *O. rufipogon* Griffith (1851). The type sheets of none of these species are available to me, and so I have left the point undecided and provisionally accepted Prain's varietal name. A good description of this wild rice is given by Bor[17], Backer[2] (under *O. fatua* Koen.) and Watt[18] (under *O. sativa* Linn. var. *bengalensis* Watt).

The cultivated rice *O. sativa* Linn. embraces wide variations in forms, and in all probability it is a composite species of polyphyletic origin. Griffith says, "It has always appeared to me that the union of all the different kinds of rice into one *O. sativa* Linn. was arbitrary. Roschevicz[5] says, "Our cultivated rice is of polyphyletic origin and that its different groups and varieties may have arisen from different species of wild rice belonging to the section *Sativa* Roschev., or from hybrids between the wild rices of this section and cultivated ones". Roschevicz also admits that *O. sativa* Linn. represents in all probability a complex of small independent species.

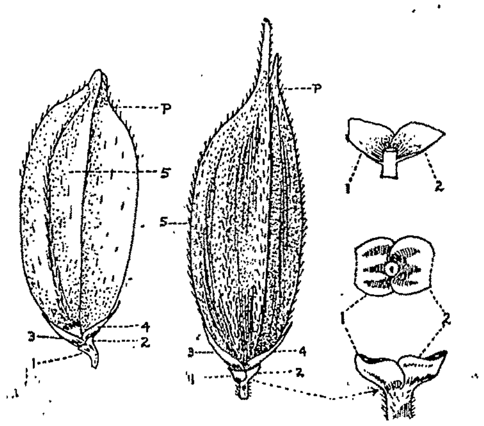
In Africa, some varieties of a cultivated rice approach *O. breviligulata* A. Chev. et Roehr. by the characters of ligule, the thickness of panicle, the strong thick awn, and Chevalier[1] rightly thinks that this wild species should be regarded as the ancestor of *O. glaberrima* Steud. which is largely cultivated in west tropical Africa along with *O. sativa* Linn.

The Rice Spikelet

The development of a large number of spikelets in the panicle is no doubt the primary cause of the reduction of some of the floral and extra-floral parts which has made the morphology of the rice spikelet a subject of special interest to botanists. The commonly known interpretation which is also found in some of the text-books is that the rice spikelet has four scales, of which the lower two are considered as non-flowering and the third large boat-shaped structure as the flowering scale (or lemma). In the axil of the lemma and between it and a similar structure, the palea, the flower is borne. There are two other very minute and extremely reduced scales at the tip of the pedicel which have been treated by many botanists as mere outgrowths. But the fact that these are constantly present and often distinct and better developed in some species shows that these are significant structures and have to be interpreted.

In 1900, Stapf[6] suggested that the rice spikelet theoretically or normally consists of six scales, of which the two lowest are very minute and more or less confluent with the tip of the pedicel and rarely discernible except with the use of a high-powered lens. The spikelet is therefore only apparently articulate with the pedicel, the real articulation being above these two rudimentary glumes. The two following structures, also empty, are usually small and one or rarely both are sometimes suppressed. The next one is the flowering scale (fertile lemma) and the uppermost the palea. The palea is very anomalous, being three-nerved and as coriaceous as the fertile lemma. In 1908, Cooke[7] arrived at the same interpretation and described the spikelet of the genus *Oryza* as having six scale-like structures. In his description of *O. coarctata* Roxb. he referred to the lowest pair of these scales as "two opposite minute appressed rounded or truncate thick scales, one attached lower than the other". Later Graham[8] made a particular study of the upper end of the pedicel of rice spikelet, and concluded that the enlargement at the tip is generally annular and in many varieties this structure becomes scale-like. Both Cooke and Graham admitted the presence of two scaly structures at the tip of the pedicel. These scales, although somewhat reduced in *O. sativa* Linn., are better developed in *O. ridleyi* Hook.f., while they are relatively large, clearly defined and well developed in *O. australiensis* Domin.

Other supporters of Stapf's view are Arber[9], Hubbard[10] and Michaud[11]. Arber made serial sections through a young rice spikelet which convinced her that the apical outgrowth at the tip of the pedicel really represented two outer glumes in an extremely reduced form. Hubbard, in his discussion, confirmed Stapf's interpretation, and also showed with a very ably executed drawing that this particular pair of glumes was exceptionally well developed as two distinct semi-oblate structures. Lastly, Michaud's discovery of abnormal florets in the axils of the pair of scales commonly considered as non-flowering indicates that these should be considered as flowering scales (or lemmas), although they are usually sterile. This naturally suggests that the spikelet of rice is theoretically three-flowered and consists of six scales and one flower as stated by Stapf. This view may be regarded as the best interpretation of the rice spikelet and is shown in Fig. 1. The lowest pair of scales should be considered as the glumes (true), the next pair of scales as sterile lemmas and lastly the fertile lemma enclosing a flower between it and the usual coriaceous palea.



O. sativa Linn. *O. australiensis* Domin
1, 2, glumes ; 3, 4, sterile lemmas ; 5, fertile lemma ; *P*, palea.

Fig. 1

Stapf arrived at his interpretation of the rice spikelet only after careful examination of considerable herbarium and fresh material. His supporters, too, examined the spikelet from different points of view and came to the same conclusion. The present writer has also examined all the species of *Oryza* and agrees with Stapf and others. But Backer[3] has recently opposed this interpretation, and pleaded for a reversion to the older theory of regarding the lower pair of scales as mere cupular outgrowths of the pedicel tip and the sterile lemmas as the glumes. It is not known whether he examined the materials of species like *O. australiensis* Domin and *O. ridleyi* Hook.f. or whether he consulted the publications of Arber, Hubbard and Michaud (loc. cit.). In any event, he did not say so in his discussion. Backer has also erred in describing Stapf's view as merely theoretical, whereas his own might equally well be so described, since he compares the pedicel tip of *Oryza* with true examples of cupular structures from *Asthenochloa*, a genus belonging to a very different and distinct tribe of grasses. An examination of the spikelet of *O. australiensis* Domin would show quite clearly that these two scales are placed one *above* the other and not in the form of a cup, as is commonly imagined, and as is found in *Asthenochloa*.

Peterson[12] and Parodi[13] independently advanced a somewhat different view on the structure of the rice spikelet. Their views involve certain bold assumptions with which I cannot agree. According to them the rice spikelet essentially represents the union of two florets, in which the paleas of both and the pistil of one have disappeared. The two large scales enclosing the flower are then considered as two fertile lemmas. If we accept their view that the so-called palea is really a lemma of the theoretical second flower, then in a serial section this would appear after the point of insertion of the first flower is well passed. But Rossberg[14] has shown that this is not the case and that the so-called palea appears to originate beneath the first flower. This reduces the second fertile lemma of Peterson and Parodi to the status of a palea. The present writer has no doubt that this structure is truly a palea, as in a mature caryopsis. the hilum points towards it. Incidentally, Rossberg has also tried to explain the unusual three-nerved palea of rice. According to him the palea evolves in a grass spikelet by the intergrowth of two originally separate leaves or leaf-primordia. These primordia have one or two nerves each and we get a two- or four-nerved palea by their lateral fusion. It has been reasonably suggested that the three-nerved palea is derived from a four-nerved one by the union or coalition of the two inner nerves or by the replacement of the inner two by a single nerve.

The Genus *Oryza*

The genus *Oryza* belongs to the Oryzeæ tribe of grasses. This tribe is characterized in having plants which are usually hygrophilous or aquatic and having small similar or dissimilar one–three-flowered spikelets, reduced scale-like sterile lemmas and minute glumes below, disarticulating rachilla, three–nine-nerved lemma and palea and usually six (rarely three, two or one) stamens. In the old world, genera like *Leersia*, *Potamophila*, *Oryza* and *Hygroryza* are well developed, while in America these are counterbalanced by the development of genera like *Luziola*, *Zizaniopsis* and *Hydrochloa*. The genus *Lygeum*, which was originally considered to belong to the tribe Oryzeæ, has now been separated out on account of its characteristic chromosomes. Genera like *Anomochloa* and *Reynaudia* are also now excluded from this tribe for other obvious reasons. The tribe Oryzeæ is subdivided into two groups, Oryzineæ and Zizaninæ, on the basis of hermaphrodite and unisexual flowers. A general account of these genera with suitable keys has been given by Prodoehl[15] and Bews[16]. The genus *Oryza* is undoubtedly the most important in the tribe and should be re-defined along the lines of Stapf's view discussed above. It consists of twenty-three species distributed in the warmer parts of Asia, Africa, Australia and America. Fig. 2 shows the general distribution of the species.

The species which I accept as good species and are referred to in the map are as follows: 1, *O. alta* Swallen; 2, *O. australiensis* Domin; 3, *O. brachyantha* A. Cheval. et Roehr.; 4, *O. breviligulata* A. Cheval. et Roehr.; 5, *O. coarctata* Roxb.; 6, *O. eichingeri* Peter; 7, *O. glaberrima* Steud.; 8, *O. grandiglumis* (Doell) Prodoehl; 9, *O. granulata* Nees et Arn. ex Hook.f.; 10, *O. latifolia* Desv.; 11, *O. meyeriana* (Zoll. et Mor.) Baill.; 12, *O. minuta* Presl; 13, *O. officinalis* Wall. ex Watt; 14, *O. perennis* Moench; 15, *O.*

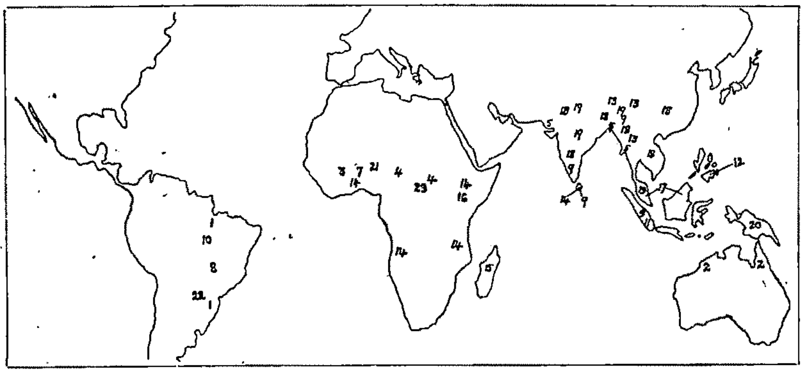


Fig. 2. DISTRIBUTION OF WILD AND CULTIVATED RICES

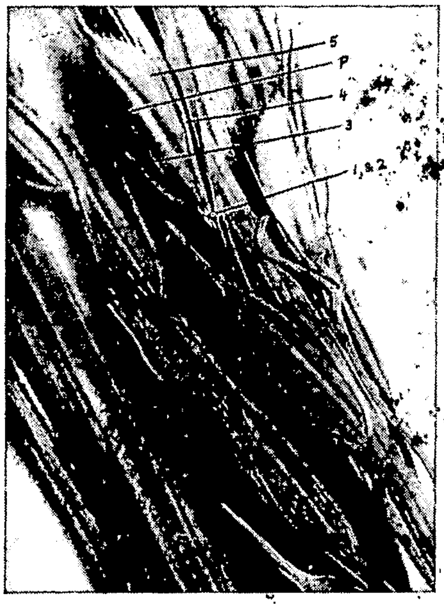

Fig. 3
O. ridleyi Hook.f.

perrieri A. Camus; 16, *O. punctata* Kotschy; 17, *O. ridleyi* Hook.f. (Fig. 3); 18, *O. sativa* Linn.; 19, *O. sativa* Linn. var. *fatua* Prain; 20, *O. schlechteri* Pilger; 21, *O. stapfii* Roschev.; 22, *O. subulata* Nees; 23, *O. tisseranti* A. Cheval.

The cultivated area of *O. sativa* Linn. is not shown in the map. It is cultivated throughout south-east Asia, China, New Guinea, Persia, Egypt, east, central, and west tropical Africa, Italy, Spain, and Central and South America.

A fuller account, with a key to the species and their synonymy, will be published elsewhere.

I am indebted to Dr. S. D. Chaudhury, Economic Botanist, Assam, for directing my attention to the subject, and also to my colleague, Mr. C. E. Hubbard, for valuable help in the preparation of this article.

ANIMAL DISEASES AND HUMAN WELFARE

IN March, 1946, the Section of Biology of the New York Academy of Sciences held a conference on the "Relation of Diseases of the Lower Animals to Human Welfare", and the nine papers read before this conference have been published in the *Annals* of the Academy (48, Art. 6, pp. 351–576; 1947). These papers, each of which is contributed by an expert, deal with rabies, equine encephalomyelitis, psittacosis and diseases related to it, brucellosis, plague, tuberculosis, anthrax, swine erysipelas and various animal parasites transmissible to man. In his introductory address, W. A. Hagan points out that the authors of the various papers consider primarily diseases of animals which are more or less directly transmissible to man, but that these diseases also affect the welfare of mankind by their economic effects. Obviously, for example, they affect our food supplies and, in addition, many people depend for their livelihood upon the rearing of farm animals.

The statistics given by Hagan of the losses inflicted by disease upon farm animals in the United States certainly bring home to us, especially just now when world food supplies are so difficult, the very great importance of the study of animal diseases. Nearly half the pigs born in the United States die before they reach marketable age. To this loss must be added the loss of the grain fed to them and also the increased cost of the products derived from the pigs which do survive. About a quarter of the 'adult chickens' die from disease each year in the United States, and one cow out of every four or five contracts inflammation of the udder (mastitis), with a consequent serious reduction of the milk supply and an increase in its price. The total losses from animal diseases in the United States are, Mr. Hagan thinks, probably smaller than they are in any other major country. Rightly he calculates not only the losses due to actual deaths, which represent only a fraction of the total loss, but also the effects of various kinds of parasitic animals which reduce the vitality of farm stock and render them more liable to diseases caused by other agents. As Mr. Hagan puts it, losses due to morbidity are much greater than those due to mortality.

A table of losses in 1942 due to various causes, which was compiled by the United States Bureau of Animal Industry, places the total losses due to parasitic animals alone at 290 million dollars, which is 69 per cent of the total animal loss of 418 million dollars. Chronic infectious diseases accounted for a loss of 70 million dollars. Acute fatal diseases, on the other hand, caused only 15 per cent of the total loss, and more than three quarters of this amount was due to a single disease—hog cholera. These figures, startling as they are, are considered by Mr. Hagan to be far too low. He would place the total annual loss at more than a thousand million dollars.

There is, however, a brighter side to this grave picture. The table given also shows that some of the great scourges of farm stock in other countries have been eliminated, or nearly eliminated, from the United States. Tuberculosis of cattle, for example, which is still a serious scourge of Britain and other countries, has been almost eradicated from the United States; and rinderpest, foot-and-mouth disease, bovine piroplasmosis and contagious pleuropneumonia have also been wiped out.

These are great achievements. Their value in terms of the relief of animal suffering is incalculable. Their economic value to man can be gauged by reference to the figures given above. Nor must we forget that many of the major diseases of farm stock are communicable to man, tuberculosis being in the forefront of these. It would seem, indeed, that, if the achievements recorded in this series of papers could be repeated in all the great food-producing countries of the world, the present urgent problem of the world's food-supplies would either disappear or would be very much less difficult to solve. How much is being done in various countries is evident in the articles which appear in this important publication. Unhappily evident also, however, is the gravity of the menace of the diseases which still remain to be overcome. The conquest of these may take time; but it cannot long resist the kind of spirit and effort which veterinarians all over the world, and the medical men who work with them, are contributing to the international service of mankind.

G. Lapage

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Speech Therapist—The County Medical Officer, County Hall, Hertford (August 23).

University Fellowship in Engineering, University Post-graduate Studentships (*a*) Kitchener (Engineering), (*b*) David Rew (Electrical Engineering), (*c*) Joseph and Lucy Chadwick (Engineering), —The Registrar, The University, Liverpool (August 23).

Assistant Professor of Mining, and an Assistant Professor of Geology, at the Faculty of Engineering, Fouad I University, Giza, Egypt—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (August 31).

Senior Lectureship in Accounting at the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (August 31).

Professor of Oceanography (biological, physical, or both) in Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (August 31).

Edward A. Deeds Fellowship in University College, Dundee, for research in Physical Science, viz., Engineering, Metallurgy, Chemistry, Physics, Mathematical Physics, or any cognate subject—The Secretary, University College, Dundee (August 31).

Demonstrator in Botany—The Registrar, Wye College, Wye, Kent (September 1).

Readership in Colonial Administration tenable at the London School of Economics—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 4).

Assistant Lecturer in Applied Mathematics—The Registrar, University College, Hull (September 6).

Technician in the Anatomy Department—The Warden and Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London, W.C.1 (September 6).

Lecturer (Grade I) in the Physiological Department (Lecturer in Histology)—The Secretary, The University, Edmund Street, Birmingham 3 (September 6).

Lecturer or an Assistant Lecturer (Grade II or III) in Botany—The Secretary and Registrar, The University, Bristol (September 10).

Senior Principal Scientific Officer or Principal Scientific Officer in the Armament Research Department of the Ministry of Supply in London—The Secretary, Civil Service Commission, Scientific Adviser's Branch, 27 Grosvenor Square, London, W.1, quoting No. 1961 (September 18).

Lecturer in Anatomy, preferably with some experience in Histology—The Secretary, The University, Aberdeen (September 18).

Vice-Chancellor, and a Senior Lecturer in Geology, at the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 30).

Professor of Celtic Languages and Literature—The Secretary, Queen's University, Belfast (September 30).

Senior Plant Breeder and a Senior Plant Physiologist under a Cocoa Research Scheme for the West Indies—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2 (October 1).

Professorship of Sociology at the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (October 14).

Lecturers (3) in Physics in the University of Queensland—The Agent-General for Queensland, 409 Strand, London, W.C.2, or The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Brisbane, October 18).

Alan Johnston, Lawrence and Moseley Research Fellowship into the problems of human and animal health and diseases and the biological field related thereto—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (November 1).

Foulerton Research Fellowship in Medicine—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (November 1).

Demonstrator in the Department of Physiology—The Registrar, University College, Nottingham.

Senior Laboratory Technician (with extensive experience in pathology, bacteriology and haematology)—The Dean, Ophthalmic Institute, Moorfields Eye Hospital, City Road, London, E.C.1.

Lecturer in Physics—The Acting Principal, Royal Technical College, Peel Park, Salford 5.

Lecturer in Geology and Biology, a Lecturer in Physics and Chemistry, and Lecturers (2) in Mathematics—The Principal, Derby Technical College, Normanton Road, Derby.

Assistant Lecturer in Agricultural Chemistry (Insecticides and Fungicides)—The Registrar, The University, Reading.

Assistant Lecturer in the Department of Engineering—The Registrar, University College, Singleton Park, Swansea.

Medical Biochemist (male or female)—The General Superintendent and Secretary, Salford Royal Hospital, Salford.

Scientific Assistant—The Director, Imperial Bureau of Dairy Science, Shinfield, Reading, Berks.

Lecturer (*a*) in Physics, and (*b*) in Biology, at the Queen Aliya Institute—The Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7.

Senior Physics Technician at the biological research unit being established at the Atomic Energy Research Establishment, Harwell—The Medical Director, Medical Research Council Unit, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Assistant Masters (*a*) in General Science and Chemistry, and (*b*) in History and Geography, at the King Faisal College—The Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7.

Research Assistants (2) to investigate insect and nematode pests of sugar beet—The Secretary, School of Agriculture, Cambridge.

Professor of Psychology, a Professor of Education, a Professor of Mathematics, a Professor of Chemistry, a Professor of Social Sciences, a Professor of Physics, a Professor of English Language and Literature, and a Lecturer in Physics, at the Higher Teachers' Training College, Baghdad—The Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7.

Secretary to the University—The Secretary, The University, Edinburgh.

Professor of Physics, a Professor of Mechanical Engineering, a Professor of Electrical Engineering, a Professor of Civil Engineering, a Lecturer in Physics, a Lecturer in Mechanical Engineering, a Lecturer in Mathematics (Descriptive Geometry), a Lecturer in Civil Engineering, a Lecturer in Electrical Engineering, and a Lecturer in Architecture, at the Engineering College, Baghdad—The Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7.

RECRUITMENT AND EFFICIENCY IN THE CIVIL SERVICE

THE Prime Minister, in a statement on the Civil Service on June 24 in the House of Commons, paid a well-deserved tribute to the Service as a whole. This praise was timely, for much current criticism of the Civil Service has been both unfounded and unfair, and has been directed against officials when it should rightly have been directed against those responsible for the policies which the Civil Service is called upon to execute. Mr. Attlee was right to repudiate the fashion of slighting the Civil Service, and to point out that we shall neither get the best out of the Service nor be able to recruit to it the energetic and able young men and women it needs if the practice of depreciating its work continues.

Much less satisfactory, however, was that part of the statement dealing with the future plans for reducing the size of the Civil Service. The Prime Minister gave four main reasons for not expecting large reductions at the present time. There is still much work to be done arising out of war conditions, such as work on war damage and re-settlement. While shortages compel the retention of rationing and other controls, a considerable staff is required for such work, amounting to 44,000 of the Civil servants employed on temporary work. Then, measures approved by the House, such as those dealing with the social services, education and civil aviation, cannot be implemented without such staff; and finally, there are the large staffs who, without substantially changing their duties, will shortly be transferred from outside the Civil Service to the Ministries of Agriculture and of National Insurance.

Up to a point, these are valid reasons; but they make it the more imperative that there should be a radical reconsideration of the systems of controls and of the internal organisation of the Civil Service from the point of view of the most efficient use of available man-power. Apart from the efficiency of a particular system of control, there may come a point when retention of the control does not justify the expenditure of man-power on its continuance. The same man-power expended on productive purposes might, even where an imported commodity is concerned, more than offset the drawback of increased import to supply a reasonable demand and prevent scarcity. If it is to be accepted, as the Prime Minister said, that the size of the Civil Service depends mainly on the jobs it is given to do, it is an over-riding imperative in the present man-power situation that the Government should see that these jobs are held in such constant review that all non-essentials are eliminated as conditions change. It is equally important in such a review that the effect on the national efficiency and economy as a whole should be kept in mind. The Prime Minister's statement referred to the 258,000 out of a total of 722,000 non-industrial Civil servants who are in the Post Office. The repeated criticism of the recent curtailment of postal services suggests that the cutting down of staff has been dictated more by near-sighted economy than by a broad view of the importance and implications of an essential service. It is not too much to say that the restrictions have more than offset many of the improvements in speed of communication which applied science has brought, and given us in Britain to-day a postal service well below the standard of that of the nineties of last century.

Both these factors bear on the question of recruitment, to which the Prime Minister devoted the latter half of his statement. Unless a high standard of public service is maintained and administrative review continually eliminates redundant posts, the mere cessation of the attacks to which the Prime Minister referred will be of little avail. Recruits of the high standard required will neither be attracted to the Service nor remain with it unless they find in their work the satisfaction of genuine public service.

That was a point effectively made by Sir Oliver Franks in his lectures on "Central Planning and Control in War and Peace". The satisfaction of doing a job related in a direct and intelligible way to the national need should be an incentive which counts for more than a little in helping the Civil Service to recruit men and women of the type it needs. So far as recruitment to the Service is concerned, however, Sir Oliver did not discuss the aggregate size of the Service; he limited himself to insisting on the need for providing the Civil Service with more experts possessing both specialized training in the techniques of forecasting and estimating and knowledge of the world, and on the urgent need of relieving the chronic overwork of senior Civil servants, particularly those in departments dealing with economic affairs.

Sir Oliver made two suggestions here: first, the use of advisory groups of men drawn largely from industry and commerce, and secondly, the creation of additional posts of 'second secretary', free from departmental duties. From the point of view of organisation, it might well be argued that the latter suggestion does not go far enough, and that it would be sounder practice to separate the administrative and the planning or advisory responsibilities of the 'permanent secretaries' so that no one individual carries the responsibility for running a large department and for planning and advising the Minister on policy. The essence of both suggestions, however, is not merely to provide the senior Civil servant with that degree of leisure upon which sound judgment in planning depends, but still more the association with the Civil Service of men with a wider outlook, experience and training than at present.

This is one of the main points made in a recent broadsheet entitled "Recruiting Civil Servants" issued by Political and Economic Planning (No. 266. May 23, 1947). The main purpose of this broadsheet, which is a preliminary study prepared by the P.E.P. Manpower Group, is to examine the extent to which the principles and methods of recruitment and training affect the way in which jobs are done. It is pointed out that since the jobs entrusted to Civil servants are the result of policy decisions taken at the political level, it is only in the way they do the jobs given them that Civil servants can legitimately be criticized. The broadsheet considers in turn the main classes of the Home Civil Service and then the Foreign and Colonial Services, but the administrative class is discussed at greatest length.

Hitherto, the administrative class has probably been weakest on questions of organisation and management, as was indicated in the Sixteenth Report from the Select Committee on National Expenditure for the Session 1941–42; and the report of the Assheton Committee on the Training of Civil Servants has since formed the basis for a serious effort to give Civil servants a systematized professional training. A director of training and education was appointed at the Treasury in January 1945, with responsibility, in association with the joint Whitley Council on Training, for exercising general control and guidance over training policy throughout the Service and for conducting training courses where this can be done better centrally than in each department. All the larger departments have now organised schemes of training, giving particular attention to making proper arrangements for receiving the new entrant and helping him to understand the enormous organisation he has joined.

The administrative class needs, however, a wider variety of talent than it has had in the past. The kind of men likely to improve defects in the organisation of the Service are those who would make good business executives: men of good intelligence and with outstanding qualities of personality—imagination, drive and balanced judgment. The P.E.P. Broadsheet urges that a proportion of the new entrants should be chosen primarily on these grounds. It is intended to restore the normal competitions not later than 1949. The majority of the entrants will then be selected by the pre-war method; but a proportion will be taken from people with at least a good second-class honours degree, who will be judged on their previous careers, coupled with an interview and a few written tests of a general character. This is a major change in the principle and method of recruitment to the administrative class, and if it is to be successful it is vital that the right qualities should be sought and that they should be satisfactorily assessed. Methods normally used by interview boards, and consequently the decisions reached, are not entirely reliable; and the experience of the armed forces in selecting officers during the War showed that better results were obtained when the interview was supplemented by practical 'situation' tests, particularly group tests. Further experiment and some modification of the methods may be required; but the technique undoubtedly offers one of the most promising approaches yet devised for assessing personal qualities, and should be adopted for selecting candidates who are to be chosen mainly on personality.

For all these encouraging signs of change, there are two features which suggest that the recommendations of the Select Committee on National Expenditure five years ago have as yet had little effect. The establishment work of the Civil Service still appears to compare most unfavourably with that of the best large firms; the re-allocation of staff lags far behind changes in the volume of work, and the allocation of individual officers often takes little account of particular qualities or of personal preferences. Such failings will not be rectified until establishment work is regarded as of the first importance and is therefore assigned to officers of the highest ability. Courses of training in modern methods of personnel and business management would be a useful supplement, and in this field at least the suggested Administrative Staff College might well make a valuable contribution towards increasing the efficiency of the Civil Service.

On the professional, scientific and technical classes of the Civil Service, Political and Economic Planning in this broadsheet merely observes that the method of selection, designed primarily to assess a candidate's professional ability, seems to be adequate, and that conditions of service and salaries for scientific workers are now attracting many men and women who might otherwise have taken up academic appointments, So, too, of the Colonial Service, the broadsheet sees no reason to doubt that the courses of training. comprehensive and imaginative in scope, which have been entrusted to the universities, will be well conducted; and suggests that the Foreign Service should devote equal care to planning the training of new recruits, including suitable courses at universities in Great Britain and abroad. In particular, the six months training which it is already proposed should be spent in the study of economic, industrial and social questions will require very careful planning. It will not be enough for officers merely to tour Government departments and industrial concerns. Such visits should be the practical complement of an academic course.

The two final conclusions of this broadsheet bring us right back to the Prime Minister's statement. First, there is the warning against sacrificing training schemes to a desire to cut staff. Training makes for a more efficient staff, and an efficient staff can do the same amount of work with fewer workers than an inefficient one. Whatever decisions of policy the Government may take which affect the amount of work required of the Civil Service, the man-power of the country as a whole demands that the most efficient use shall be made of everyone who enters the Civil Service at whatever level, and that no one shall be retained who is unsuitable for his or her work or engaged in duties that are no longer indispensable.

For the same reason, the second conclusion is vital. Methods of recruitment and training should be reviewed from time to time in order that they may be adapted to changes in the national system of education and in the functions of the Civil Service. That, however, is only a small part of that long-neglected recommendation of the Tomlin Commission concerning surveys forming part of a systematic and periodic overhaul of the machinery of Government, to which the Select Committee directed attention. There is no suggestion in the Prime Minister's recent statement that any importance is attached to such efficiency audits at any level, and yet they are at least as essential as when the Select Committee reported in 1942.

It is idle for the Government to call so loudly for increased efficiency in production unless it insists on its own departments, such as the Post Office, making serious efforts to relate the loss of productive efficiency in the country caused by delays in essential services with the man-power savings in the staff reductions that have been made. It may be that all the possibilities of re-organisation and other factors in the General Post Office have been considered and correctly weighed; but the public is entitled to be told, and all the more for the overwhelming amount of goodwill towards this department which was manifest in the recent debate. The existence of such goodwill is one vital factor in obtaining the right kind of staff in any part of the Civil Service, and in maintaining its keenness and efficiency when recruited. No amount of care expended on recruitment or training can compensate for mistakes in policy and administration by the Government itself, which dissipate public goodwill and also the incentive inside the Service coming from the satisfaction of a visible public need and its generous appreciation.

BIOCHEMISTRY OF CANCER

Biochemistry of Cancer

By Jesse P. Greenstein. Pp. viii+389. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1947.) 7.80 dollars.

THE deficiency in books on laboratory cancer research is particularly unfortunate since so many new workers are turning their attention to the problems of malignant disease. The present volume is therefore assured of a wide welcome, representing as it does a valuable, indeed indispensable, addition to the cancer literature. The fact that this book follows so soon after K. Stern and R. Willheim's "The Biochemistry of Malignant Tissues", which was published in New York in 1943, illustrates the great attention now being given to biochemistry in relation to cancer in the United States, where it is widely felt that the more dynamic approach to the problems of normal and malignant growth which biochemistry supplies should be fully developed to supplement and reinforce the well-tried methods of classical histology.

It is instructive to compare these two recent books, both of which are good of their kind though entirely different in content and in mode of thought. Stern and Willheim set out to write a conventionally planned systematic work of reference, classified under tissue components and seeking completeness, and therefore largely uncritical in the selection of data. Dr. Greenstein, on the other hand, has exercised much discrimination in what he includes, and the whole book is strongly flavoured with a vigorous and critical personality and a decidedly individual outlook. His choice of material will not please everyone, and the emphasis which he puts on very recent work (the book is fully up to date) sometimes leads to the exclusion of older and more basic investigations and may thus give some readers an unbalanced view of the subject. For this reason a combination of the study of these two books has much to recommend it. Dr. Greenstein's numerous tabulations of a wide variety of numerical data are particularly useful, and his method of approach undoubtedly possesses the great advantage of avoiding that tedious chronicle of confirmatory, and alas of contradictory, observations which are characteristic of most books on cancer. In this subject the temptation to jump ahead of the available data is only to be resisted by the strongest self-control, and in this respect the modern worker ought to be in a much better position than his predecessors, many of whom were obliged to restrict their experiments to a few mice. One of the great merits of the National Cancer Institute at Bethesda, of which Dr. Greenstein is head biochemist, is that it possesses facilities and staff covering the whole range of scientific activities needed for cancer research. How great a contribution this large-scale organisation of research has made to the biochemistry of cancer is made abundantly clear in this book, though the author is under no illusion that new discovery, as distinct from the application of known principles, can ever be mass-produced (see p. 375).

After a brief introductory chapter on the origin, transmissibility, and general nature of cancer, the three main sections deal with induction of tumours (108 pp.), controlling factors (34 pp.), and properties (200 pp.). In the first of these, the extrinsic factors, including the known chemical and physical carcinogens, are described; a rather brief account of the pioneer investigations of E. L. Kennaway, J. W. Cook, and their colleagues at the Cancer Hospital being followed by a somewhat more detailed description of the subsequent American work. This is succeeded by a useful section on the metabolism of the carcinogens in the animal body, a matter which may help to explain the differences in carcinogenic power found in different species. The reviewer may perhaps mention that the explanation suggested for the loss of carcinogenic power of benzpyrene when dissolved in solvents containing phospholipins (see p. 63) does not hold for experiments in which the amount of benzpyrene actually injected was determined by analysis (F. Dickens and H. Weil Malherbe, *Cancer Research*, 2, 560 (1942); 4, 425 (1944); 6, 161, 171 (1946)).

Under the heading "Intrinsic Factors" is a useful account of the influence of sex-hormones and of the mammary tumour inciter, the milk-borne factor discovered by J. J. Bittner in 1939, which renders certain strains of mice liable to breast cancer when they become older. Although no evidence yet indicates that this observation applies to other species, probably most cancer workers would attribute to it higher importance than Dr. Greenstein gives it here, if only because of its remarkable theoretical significance. The same applies to the interesting observation, now fully confirmed, that cancer can be induced in mice by suitable extracts of human tissues. Although the activity of such extracts is rather feeble, and it is not yet proved that the carcinogenic properties do not arise through alteration of the extracted substances during the manipulations, it seems to be going too far to suggest (p. 134) "that the results merely demonstrate the relative susceptibility of mice to carcinogenic agents of most any and all sorts (*vide infra*)". One has the impression that much of this book was hastily written, for example, the frequent use of *vide infra* for references to earlier pages, the occurrence of uncorrected printing errors, and the occasionally confusing English, as on p. 260, where the account of the cytochrome system is difficult to follow. This is a pity, for the excellent material deserves a more careful presentation.

The final chapters on the properties of tumours contain the most comprehensive account of the enzymic distribution in cancer tissue which has yet been written, and coming from one who has himself made valuable contributions to this subject, this authoritative section would alone have justified the publication of the book. As in the other chapters, full bibliographies are included, and there are author and subject indexes. The general conclusion is that the cancer cell is working with most of its enzymic machinery fully extended to meet the demands upon it, and has therefore less reserves of metabolic catalysts available than the normal cell possesses. This is an important generalization, and, if it stands up to further critical experiments, may perhaps form the basis of a future scientific therapy of cancer.

F. DICKENS.

DIET AND VITAMINS

The Nation's Food

A Survey of Scientific Data. Edited for the Society of Chemical Industry (Food Group) by A. L. Bacharach and Theodore Rendle. Pp. xvii+349. (London: Society of Chemical Industry, 1946.) 18*s*. net.

Vitamins and Hormones

Advances in Research and Applications. Edited by Prof. Robert S. Harris and Assoc. Prof. Kenneth V. Thimann. Vol. 4. Pp. xvii+406. (New York: Academic Press, Inc., 1946.) 6.80 dollars.

HERE are two volumes which no serious worker on nutrition can be without. In "The Nation's Food" will be found an authoritative summary of almost all that is at present known about the nutritive value, and the chemical and even physical properties, of British foods. The first section of the book deals with the egg as food, the second with the potato as food, the third with vegetables as food; and parts four, five, six and seven, respectively, with cereals, meat, fish and milk, all treated "as foods". Thus no important article of diet is omitted. Each of these seven sections is further subdivided, in a methodical manner, into a series of chapters, dealing in turn with such aspects as the biology of the food in question, its chemistry, nutritive value, production, effect of cooking, storage, and so on. These chapters—twenty-seven in all—are contributed by the leading experts in each field; and thus the book is bound to be useful both to the specialist, who will need it for reference and for study, and also to those whose interests are more general, including, no doubt, caterers, dietitians and food manufacturers.

The Food Group (and its Nutrition Panel), a constituent section of the Society of Chemical Industry, under whose auspices the papers published in this book were originally delivered as a series of lectures, are deserving of our warmest thanks. So also, assuredly, are the authors and the editors, who have gone to so much trouble in their work of extending, revising and editing their manuscripts since these lectures were first given, in order that we may now have their expert knowledge before us for our more permanent use.

"Vitamins and Hormones" is likewise an authoritative compilation by a number of experts; and volume IV, the latest to appear, will be as welcome as were the earlier numbers, and will be needed by all those departmental libraries which specialize in these branches of science. The plan here is somewhat different from that of the book first reviewed, for in "Vitamins and Hormones" contributions are published not in any logical sequence but in the necessarily more fortuitous order in which they could be commissioned and delivered. Thus volume IV is made up of the following contributions in order: "The Newer Hematopoietic Factors of the Vitamin B-Complex", by J. J. Pfiffner and Albert G. Hogan; "Nutrition and Resistance to Infection: the Strategic Situation", by Howard A. Schneider; "Manifestations of Nutritional Deficiency in Infants", by F. W. Clements; "Effect of B Vitamins on the Endocrinological Aspects of Reproduction", by Roy Hertz; "Nutritional Therapy of Endocrine Disturbances", by Morton S. Biskind; "The Thyroid and Diabetes", by Bernardo A. Houssay; "Thyro-active Iodinated Proteins", by E. P. Reineke; "The Protein Anabolic Effects of Steroid-Hormones", by Charles D. Kochakian; "Methods of Bioassay of Animal Hormones", by Sidney A. Thayer.

The style and standard of the contributions vary considerably: some of them are relatively exhaustive in scope, some less so; some are in the form of critical appraisals of the present outlook, whereas others are more in the nature of a collection of abstracts. A useful feature is the system of headings, sub-headings, and sub-sub-headings, which appear both in the table of contents, and in the actual review article itself. This makes for ease in consultation. For example, in the review on "Methods of Bioassay of Animal Hormones", by Sidney A. Thayer, "Section IX" of the review is concerned with "Bioassay of Adrenal Cortical Hormones", "Section IX: 2" with "Bioassay of Adrenal Cortical Hormones: Deposition of Glycogen in Fasting Adrenalectomized Rats", "Section IX: 2, a" with "Bioassay of Adrenal Cortical Hormones: Deposition of Glycogen in Fasting Adrenalectomized Rats, Experimental", and "Section IX: 2, a-γ" with "Bioassay of Adrenal Cortical Hormones: Deposition of Glycogen in Fasting Adrenalectomized Rats, Experimental—Final Assay Procedure".

Not very many workers on vitamins are active in the field of hormones, or *vice versa*, and some readers may have questioned the practical advantage of joining the two subjects together in the one periodical. In their preface to the present volume, the Editors take up this very point. They refer to the "increasing interrelationship between vitamin and hormone research", which as they say is "exemplified in three articles in the present review". They therefore conclude that this "justifies the Editors' initial feeling that the bringing of reviews of these two fields under one cover would prove realistic and helpful". LESLIE J. HARRIS

GEOLOGICAL GUIDE-BOOK OF OXFORD

The Geology of Oxford

By Dr. W. J. Arkell. Pp. viii+268+6 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1947.) 20*s.* net.

NEARLY eighty years ago there issued from the Clarendon Press Phillips' "Geology of Oxford and the Valley of the Thames", a classic among geological guide-books. Here, from the same Press, with a shortened title and reduced bulk, appears another. Stratigraphers who possess, and perpetually consult, Dr. Arkell's "Jurassic System" will not need to be assured that "The Geology of Oxford" is an erudite, documented and yet readable book. Although the area dealt with in detail is comprised within a ring of some thirty miles radius around Oxford, comments and comparisons range over Europe and beyond, so that the book provides a sketch of Mesozoic and later stratigraphy in which one small portion is elaborated. It is essentially a book for students, but for students everywhere.

A concise first chapter introduces the Palæozoic platform on and about which the main subject-matter is to accumulate. The contrast between "Palæo-Europe" (on which Oxford stands) and "Meso-Europe" (which is attached to it along the south side of the Mendip–Ardennes line) explains the diversity of the post-Triassic sedimentary history of the area.

The remaining seventeen chapters treat of the deposition, classification, deformation and disposition of the rocks of the successive periods. It is refreshing to find in their headings the good old English names that nowadays are so often lost in the intricacies of zonal nomenclature. There is nothing old-fashioned in the chapters themselves. Each starts with an uncompromising list of the zones, followed by a summary of the local and regional characteristics of each. Then come the local details; there can be few exposures within the chosen area that are not analysed with meticulous care. It is a testimony to the author's style that even these purely descriptive paragraphs, lists of fossils and all, make interesting reading.

The first ten chapters constitute an amplification, with slight revision, of the corresponding parts of the author's "Jurassic System". Such modifications in classification as appear in this newer account result, on the whole, in simplification. In the chapters dealing with the Cretaceous and Tertiary systems there seems to be an increased reliance on the work of others; these chapters are summaries of diverse opinions rather than expressions of personal conviction. This in no way lessens their value to the student, nor does it exclude ingenious and provocative comments. The author seems to accept, with but little reservation, the latest heresies in respect of the Chalk, its origin and its flints. That the Chalk Sea was relatively shallow is as sound a deduction as that it was extremely wide; but it is hard to believe that an area of water covering most of Europe could have permitted desert conditions to prevail over the surviving patches of land. Coastal sand-dunes do not necessarily imply a Saharan hinterland. Again, the author is content to postpone the segregation of silica into flints until the Montian stage (with a second gathering in the late Miocene period). While it must be admitted that much flint has 'grown' in the Chalk since Cretaceous times (it may, indeed, be forming still), some of it must surely be contemporaneous. The unshrivelled form of the ectosarc of sponges, or the ampullae of Echinoids, to mention but two common occurrences in 'flint-fossils', must have received their 'petrifying' coating within a few hours of death.

The chapters on the Pleistocene recover the personal touch and provide much valuable information and correlation of local developments. Many of the interpretations may be debatable; but that is normal for the period.

The index is a model of its kind and ensures the value of the book as a work of reference. The text-figures are adequate and clear, the author's drawings of fossils being particularly good. The plates are perhaps less satisfactory, but they are few. It is strange to find as the frontispiece to a work on Oxford a touched-up aerial view of White Horse Hill, the 'Mecca' of the men of Berkshire. But it will be realized that if criticism is reduced to such trivial points, the real reaction to this book is one of unstinted welcome; every serious student of stratigraphy, whether he works near Oxford or not, will find its facts indispensable and its arguments stimulating. H. L. HAWKINS

STRUCTURE OF SPECTRAL LINES

High Resolution Spectroscopy
By Dr. S. Tolansky. Pp. xi+292+4 plates. (London: Methuen and Co., Ltd., 1947.) 21*s*. net.

THE author of this book has given an account of the experimental techniques used in the investigation of the structure of spectral lines; but he has not stated in the introduction whether it is intended to be primarily a historical account or to be a text-book giving a critical description of methods now in use, and the book suffers from a confusion of these points of view. On one hand, there is lacking an account of the work which has been done in the past with the methods described, and on the other hand, obsolete instruments are described in too much detail; and avoidable inaccuracies seriously reduce the value of the book from both of these points of view. In spite of the length of the book, important experimental details have been omitted, too much space having been devoted to academic theoretical considerations.

The first five chapters contain a detailed account of the light sources used for obtaining narrow spectral lines; but a summarized comparison of the advantages and limitations of the different methods is not given. The description of the hollow cathode tube is concerned too much with complicated and obsolete forms of this light source. In the account of the atomic beam the advantages of the method of observation in absorption have not been fully appreciated. For example, it is stated on p. 82, "it is therefore very easy to miss weak components . . .", while in fact it is one of the merits of this method (as of all absorption methods) that it is specially suited to the observation of weak components (the weak components in the potassium resonance lines, due to the rare isotope K41, have been found in absorption, whereas they are not observable in emission).

The last ten chapters are concerned with the optical instruments used for the examination of the structure of spectral lines. A comparison is made between four instruments, the Fabry–Perot etalon, the Lummer–Gehrcke parallel plate, the echelon grating and the ruled grating. The general superiority and greater scope of the etalon is rather understated, and a quantitative comparison of the intensity of the spectra given by these instruments should not have been omitted. The detailed description of two methods, sputtering and evaporation, for preparing the metallic layers for the plates of an etalon is misleading; the impression is given that the former is a method which would still be used, while it has, in fact, been rendered obsolete by the latter. Though very few, and contradictory, measurements are available concerning the reflecting power of transparent layers of silver and aluminium, this property is made the basis of six different graphs, thus giving a wrong idea of the facts. The most important part of all of these curves, that referring to dense layers as actually used, has been reproduced from data which do not pretend to a high degree of accuracy, and is unfortunately badly wrong. Thus as a consequence of conclusions drawn from the curve giving the relationship between the reflecting power of a layer of silver and the intensity of the maxima of the fringes, it is stated: "The curve has a steep fall in the important region of 0·85 upwards. It is significant to note that an increase in reflecting coefficient from 0·85 to 0·87 (only two per cent) leads to a 50 per cent reduction in intensity. . . . The region in the neighbourhood of the 0·85 reflecting coefficient is therefore highly critical and considered judgment is necessary in preparing such films." If the curve had been drawn correctly it would have shown that the rapid fall in intensity occurs when the reflecting power becomes greater than approximately 0·95. The use of silver layers of this higher reflecting power is of the greatest importance, since it involves an increase by a factor of three in the resolving power and a reduction by a factor of approximately ten in the intensity of the background. The production of evaporated layers of the correct density is necessary for obtaining high resolving power without loss of intensity, and this can be done without the need of "considered judgment" by photo-electric measurement of the density during the course of the evaporation (using the correct value for the reflecting power); but this method is not described.

In the chapter concerned with the compound etalon, too much space is given to theoretical calculations of the properties of this instrument; a description of some of the results which have been obtained and an account of the experimental details of the methods of adjustment would have been of more value. In the discussion of the limitations with regard to the intensity of the fringes and the strength of the subsidiary maxima, the value of this instrument is much underrated on account of the assumption of wrong values for the reflecting power of silver layers and the corresponding intensity of the fringes, taken from the incorrect curve referred to above. A reflecting power of 0·8 is assumed; in fact, a reflecting power of 0·9 can be used without serious loss of intensity; there is then a reduction of the intensity of the subsidiary maxima to a small fraction of that for a reflecting power of 0·8.

The description of the echelon grating lacks an account of the work which has been done with this instrument, and fails to emphasize the importance of its limitations due to the weakness of the spectra as a result of the need for an objective of very long focal length; the advantage of the simplest form of mounting which reduces loss of light are thus underestimated. The discussion of the aberration which would be introduced by this mounting if an objective of short focal length were used is irrelevant, since the limitations due to the grain of the photographic plate preclude the use of a short focal length.

The scope of the photographs at the end of the book is rather limited, since the author has not reproduced photographs made by other workers.

Although serious errors and omissions reduce its value, this book contains much information useful for workers in high-resolution spectroscopy concerning which no comprehensive treatise has hitherto been available. D. A. JACKSON

CENTENARY OF THE CHEMICAL SOCIETY

THE Chemical Society is entitled to be congratulated on the whole programme of events arranged in celebration of its centenary during July 15–17. There were receptions and a programme of visits, and three excellent lectures besides the centenary address, all appropriate and all well arranged, and many of them displaying the same leading ideas that marked the opening ceremony and the centenary address. The first official function was indeed the opening of an exhibition illustrating one hundred years of British chemistry at the Science Museum, South Kensington, by the president of the Society, Prof. C. N. Hinshelwood, on July 14. The Minister of Education, who took the chair at the opening ceremony, emphasized not merely the vital place of the learned societies in the cultural and educational life of the community and the landmarks in the progress of chemical science to be seen in the exhibition, but like Prof. C. N. Hinshelwood, the dependence of such achievements upon men of independent, vigorous and original minds in the past.

Prof. J. Read, in his lecture at the Institution of Civil Engineers on "Chemical Personalities a Century Ago" on July 16, took a longer look at some of the founders of modern chemistry, and Prof. E. K. Rideal, lecturing simultaneously at the Royal Institution on "The Work of the Royal Institution in Physical Chemistry in Great Britain", also paid tribute to many honoured names such as Humphry Davy, Faraday, Dewar, Sir William Bragg and Sir Henry Dale. Equally, Sir Robert Robinson, in the Faraday Lecture delivered in the Central Hall, Westminster, on the afternoon of July 16, on "The Development of Electrochemical Theories of the Course of Reactions of Carbon Compounds", linked modern ideas on the electrolytic dissociation of acids and the applications of these principles to the benzene ring and theory of partial valency with the work of Faraday, in whose laboratory at the Royal Institution during Faraday's active experimental life of some forty years, fifteen major investigations were undertaken, all of which had a profound effect on physical chemistry as we know it to-day.

The dominant impression left by Prof. Read's lecture was exactly that of the international unity and fellowship which was such a distinctive feature of the dignified and impressive opening ceremony of the celebrations in the Central Hall the previous day. Prof. Read showed how those chemists who founded the Society formed part of a movement which recognized national frontiers no more than the wandering scholars of the Middle Ages, and which even then was throwing up schools of chemistry which attracted men from all over the civilized world. The birth of the Chemical Society was the outcome of an intellectual ferment as international in character as the gathering which saluted its birth. Prof. Rideal's lecture, on the other hand, illustrated incidentally the reciprocal influence of the Chemical Society on other scientific societies and institutions. The Chemical Society, as Sir Robert Robinson pointed out, in conveying greetings to the Society from the Royal Society and the other learned societies of Great Britain, had not merely stimulated the formation of other bodies such as the Biochemical Society and the Faraday Society, but had also contributed to the advancement of knowledge in many diverse fields, as was illustrated by that with which the Society of Dyers and Colourists was concerned. The influence, as Prof. Rideal noted in commenting on the fact that five of the professors in the Royal Institution had been presidents of the Chemical Society, was reciprocal, and the Chemical Society owed much to the labours of other societies.

The names in the list of some forty societies and institutions in Great Britain on whose behalf Sir Robert Robinson offered felicitations to the Chemical Society testified to the ramifications of chemical science during the century and to the industries which had been stimulated or transformed by chemical enterprise, and the proceedings on the Tuesday, above all at the opening ceremony and the centenary address, seemed to epitomize the essential spirit of the celebrations. There was colour as well as dignity in the processional entry of the delegates representing overseas Societies, headed by the president, and preceded by the Society's mace-bearer. The president's words of welcome to the representatives of nearly thirty countries were well chosen, touching briefly on the unity of science. Prof. Raymond Delaby, speaking on behalf of these delegates, responded in French. The addresses formally presented by these delegates and by the representatives of British Societies were not read at the meeting but were displayed in the Society's rooms at Burlington House, where they were to be seen at the Royal Society's reception. Mention might be made here, however, of the Swedish glass vase bearing suitable inscriptions and illustrations of chemical equipment which contained the address of the Chemical Society of Stockholm.

If the centenary address of Prof. Hinshelwood on July 15 is given pride of place it is only because it gave fuller expression to the charm of manner and keenness of thought which marked his tenure of the presidential chair throughout the celebrations. If the founders of the Society might have found it beyond their wildest dreams to expect that the head of the Government of the day would honour the Society by his presence at the centenary dinner and that the fellows of the Society and the overseas delegates should enjoy Government hospitality at the luncheon on July 15 and the garden party at Lancaster House on July 17, the explanation is at least in part to be found in the president and those like him who have linked to their scientific attainments such charm and courtesy and organising ability. That much at least can be glimpsed in his centenary address, which will worthily commemorate the celebration long after the memory of the social events and festivities is dim.

Touching briefly on the philosophical questions raised by the celebration of the centenary not of a discovery or of a person, but of a Society, he reviewed in succession the chemical scene at the foundation of the Society and at successive intervals of a generation before, attempting to discern the essential trends to which great events and personalities are related more as occasions than as causes. Here Prof. Hinshelwood challenged thought about some of the central issues of our time and formulated our task of preventing an organised society from turning individuals into slaves with all the implications for the relation of the State to science, of industries to the universities, for the organisation of research laboratories and, indeed, for the relation of every scientific worker to the laboratory in which he works and to the science as a whole. Complete individualism means chaos, but it is still the individual who counts; but his problems are different, and at every level in every organisation where men engaged in scientific pursuits those in charge must continue to wrestle with the problems of combining liberty with order to the end of finding that course which is humanly as well as technically the most effective.

Pragmatic as well as suggestive, Prof. Hinshelwood was never doctrinaire, but he did not hesitate to follow his words of appreciation for the increasing number of scientific papers coming from chemical industry, with a warning of the dangers in which military security might involve us or against the restrictions on scientific publication imposed by paper stringency or to plead for adequate facilities for meetings, and in this address he returns in conclusion to the international character of the Society and to the fellowship of those who share the love of chemistry which was so manifest at the celebrations.

Welcome as may be the generous appreciation of the work of the Society manifest in the addresses of felicitation, the hospitality extended to its fellows and guests at the receptions, visits and social functions, it is to the spirit which pervades the centenary address that we must look chiefly for the firm assurance that the second century on which the Society has entered will be no less noteworthy than that celebrated in July 1947.

ELEVENTH INTERNATIONAL CONGRESS OF PURE AND APPLIED CHEMISTRY

THE Eleventh International Congress of Pure and Applied Chemistry was held in London during July 17–24, following immediately on the centenary celebrations of the Chemical Society. Some three thousand members and delegates, including many leading personalities in all branches of chemistry, and representing thirty different countries, took part in what must have been the largest international gathering of men of science since the end of the War. A crowded programme had been arranged, consisting of meetings for the reading and discussion of papers, lectures, visits to industrial laboratories and many social events.

More than 1,500 papers were submitted for presentation. For the purpose of reading the papers selected, the Congress met in fourteen sections, representing the various branches of pure and applied chemistry. Several sessions were held jointly between different sections, and the majority of contributions were in the nature of reviews of work already published, or in the process of publication, rather than entirely new material. It is obviously impossible to give more than a very brief indication of the vast amount of ground covered. Only a small fraction of individual contributions can be mentioned, but it will be useful to summarize the main topics of discussion as they provide an excellent indication of contemporary trends in chemistry.

In Section 1 (Inorganic and Geochemistry) the first session was devoted to reactions in solids and X-ray methods, and included a general review by J. A. Hedvall of progress in this field over the last thirty years, and an account by H. L. Riley on the X-ray crystallography of amorphous carbon. At a later session, entitled "Structural Chemistry of Metals and Inorganic Compounds", L. Pauling outlined a new theory of the metallic state. Treatment of interatomic forces in metals by the method of atomic orbitals provides a qualitative explanation of the special properties of the transition metals. Other speakers discussed recent work on the structure of mixed crystals (P. Niggli), molecular compounds (H. M. Powell) and electron-deficient molecules (R. P. Bell). Further sessions dealt with geochemistry and the structure of minerals, and with radiochemistry, and included papers on francium (element 87) (M. Perey), and on protactinium (G. Boussières and H. Haissinsky). The disappointing fact that any direct reference to subatomic phenomena was excluded, brought to mind the centenary address of the president of the Chemical Society in which he expressed the hope that "the whips of commercial secrecy would not be succeeded by the scorpions of military security" in preventing the publication of research.

In Section 2 (Physical Chemistry) there were symposia on polymers, catalysis and reaction-rates, and spectra. The latter was almost wholly concerned with the absorption spectroscopy of organic compounds. The striking developments in the technique and applications of measurements in the infra-red region were reviewed by J. Lecomte, G. B. B. M. Sutherland and H. W. Thompson. E. Clar discussed the ultra-violet light absorption of aromatic hydrocarbons, and J. M. Robertson the determination of bond-length by X-ray methods. In the session on polymers, held jointly with the Textile and Elastomers Sections, about an equal number of papers were devoted to structural and kinetic aspects. H. W. Melville described the synthesis and properties of a new branch-chain type of polymer built up from cruciform and star-shaped molecules and obtained by condensing together adipic acid, ethylene glycol and a small amount of a polyfunctional alcohol, such as penta-erythritol. Two papers by H. Mark dealt with the mechanism of polymerization reactions and the configuration of polymer molecules. The composition of a binary co-polymer is related to the electron-availability at the radical end of the growing chain and at the double bond of the monomer molecule, and can be predicted from the electronic character of the substituents. J. B. Speakman described the modification of the properties of natural fibres by chemical means, for example, by successively breaking and re-uniting the cysteine cross-linkages in keratin with reducing and oxidizing agents, and by physical means. Among the topics covered in other sessions were those of mass-spectrometry, magnetochemistry and polarography, and included papers on the measurement of the rate of electrode processes by oscillographic methods (J. Heyrovsky), the thermal and photo-oxidation of olefins (I. Bateman and J. L. Bolland) and the absolute velocity of contact catalysis (G. H. Schwab).

The programme of Section 3 (Organic Chemistry) covered general organic chemistry, heterocyclic compounds, antibiotics, vitamins and growth factors, and theoretical organic chemistry, and included many contributions of outstanding interest. Of special significance from the international point of view was an account by G. M. Dyson of his new system of notation for organic compounds, which has many advantages over the rather loose nomenclature at present in use. Any compound, however complicated, can be ciphered uniquely, the number of symbols required being on the average less than half of those used with the Geneva Convention, and the ciphers are admirably suited for mechanical indexing and sorting methods. Five papers on penicillin by H. C. Carrington, K. Folkers, Sir Ian Heilbron, D. Crowfoot Hodgkin and V. du Vigneaud, and their collaborators, provided a fascinating story of what is probably the greatest concerted effort yet made by organic chemists. Of the two rival thiazolidine-oxazolone and thiazolidine-β-lactam structures, the latter is now accepted, mainly on the basis of physical evidence; but the only definite synthesis so far achieved, though in minute yield, is based on the former. The synthesis of vitamin A, a goal which for so long defied the attempts of several groups of workers, was announced by D. A. van Dorp and J. F. Arens (see also *Nature* of August 9, p. 189), and by O. Isler. The determination of the constitution of streptomycin was outlined by K. Folkers. Sir Robert Robinson discussed recent work in the strychnine group of alkaloids. The isomerization of strychnine into neostrychnine has been recognized as a simple prototropic rearrangement, and leads to a new structural formulation. Other notable contributions included the synthesis of compounds related to the auxins (E. R. H. Jones) and to pyridoxin (vitamin B_6) (A. Cohen), degradative work on amyrin (L. Ruzicka), the potato eelworm hatching factor, ecleptic acid (A. R. Todd), and testosterone (P. A. Plattner), the constellation of many-membered ring ketones (V. Prelog), and of the configuration of the hydroxyl group in cholesterol (C. W. Shoppee), the synthesis of pyrimidines (F. H. S. Curd and F. L. Rose) and of xanthines (F. S. Spring), and addition reactions of nitro-olefins (J. D. Rose), and of halogen-containing compounds to olefins (M. S. Kharash). Theoretical organic chemistry was represented by papers on the kinetics and mechanism of aromatic nitration (C. K. Ingold) and halogenation (J. P. Wibaut), the mechanism of oxidation reactions (W. A. Waters), the X-ray analysis of cyclo-octatetrene (H. Mark), and others.

In Section 4 (Biochemistry) there were sessions on enzymes and enzyme action, macromolecules of biological interest, intermediary metabolism, and proteins and protein analysis. J. D. Bernal spoke on the structure of the protein molecule, a picture of which is now slowly emerging by the combined attack of electron microscopy, X-ray and chemical analysis. F. Sanger described a new method of estimating the length of polypeptide chains in proteins and of identifying individual amino-acids by reacting the free amino-groups with 2 : 4-dinitrophenylfluoride, and separating the coloured derivatives by partition chromatography. M. Stacey gave an account of bacterial polysaccharides and H. N. Rydon described studies which indicate that hydrogen-bonding may be an essential feature in the combination of bacterial enzymes with their substrates. The emphasis in metabolic studies was on the use of isotope tracers. V. du Vigneaud presented evidence that only the sulphur but not the carbon of methionine is used in the synthesis of cysteine in rats. Studies employing radioactive phosphorus and iron indicate that there is a rapid migration of phosphorus from the plasma into the red blood corpuscles, and that average lifetime of the latter is about one month in the hen and four months in man (G. von Hevesy). The fate of mustard gas in the animal body and the mode of action of B.A.L. (British anti-lewisite, 2 : 3-dimercaptopropanol) has been investigated using radioactive S^{35} (G. E. Frances and A. Wormall, L. Young). M. el Shahat announced the discovery of a new 'H'-lactation promoting factor which is not a tocopherol.

Sections 5 and 6 (Chemistry in Relation to Agriculture and Applied Botany, and to Applied Zoology and Veterinary Science) held symposia on soil fertility, plant nutrition and fertilizers, animal nutrition, composition and quality of milk, insecticides and fungicides, and the chemotherapy of protozoal infections. Several speakers, among them H. R. Marston, R. L. Mitchell, S. A. Waksman and E. J. Underwood dealt with the role of trace elements, such as copper, selenium and cobalt, a subject on which very diverse views are still held in different countries. J. H. Quastel described his recent work on the role of manganese in biological oxidation in the soil. S. J. Rowland reported a steady decline in the solid protein content of English milk, and seasonal variations in the composition of milk in Norway and India were discussed by G. Aas and K. C. Sen. H. Hurst attributed the mode of action of D.D.T. to the indirect blocking of the cytochrome oxidase and succinic dehydrogenase systems by the storage of insecticide in the phospholipoids of the cell membranes, while H. Martin directed attention to the parallelism between the ease of dehydrochlorination and insecticidal activity in D.D.T. analogues. The chemotherapeutic uses of amidines and of phenanthridinium compounds were reviewed by H. J. Barber and by L. P. Walls.

In Section 7 (Chemistry in Relation to Food and Nutrition) Sir Jack Drummond introduced a topical discussion on the effects of dietary restrictions in man. J. R. Marrack, in dealing with the question of how can we know whether our food is doing us good, considered that the most reliable answer was provided by functional tests, for example, the level of hæmoglobin and ascorbic acid in blood, and the height and weight of children, rather than by vital statistics. A. Neuberger introduced a discussion on the role of amino-acids in nutrition. Isotope tracer experiments have established the extraordinary speed of nitrogen exchange between proteins and the dietary supply. Experiments which establish the function of methionine as a source of labile methyl groups were described by V. du Vigneaud and by L. E. Glynn. D. P. Cuthbertson discussed the marked catabolism of body protein following traumatic injury as revealed by the losses of nitrogen and sulphur in the urine.

Section 8 (Chemistry in Relation to Medicine and Therapeutics) covered a wide range of topics. Sir Howard Florey introduced a symposium on antibiotics. The rapid developments in this field are exemplified by the isolation from actinomycete cultures of more than a dozen antibiotics besides streptomycin (S. A. Waksman), and the production of a variety of compounds effective against *M. tuberculosis* by *Fusaria* (A. H. Cook). In a session on industrial toxicology, B. C. Saunders reviewed the toxic properties of fluorine compounds such as the fluorophosphonates and fluorocarboxylic acids $F.(CH_2)_n.CO_2H$. The latter are harmless when n is even, but toxic when n is odd. R. A. Peters discussed the reactions of B.A.L., and R. Spence and A. G. Maddack outlined the design of a radiochemical laboratory in relation to the protection of the health of the staff. Two further sessions, entitled "Endocrinology and Carcinogenesis" and "Drugs and Chemotherapy", included papers on doisynolic acids (K. Miescher), œstrogens related to triphenylethylene (W. Tadros), carcinogenic agents of the *p*-aminostilbene type (G. A. R. Kon), the relation between physico-chemical properties and bacteriostatic properties of acridines (A. Albert) and the empirical and rational approach to chemotherapy, as exemplified by the work culminating in the discovery of the antimalarial paludrine (F. H. S. Curd and F. L. Rose).

In Section 9 (Chemistry in Relation to Fuel, Power and Transport) there were discussions on many aspects of the production of solid and liquid fuels, carbonization and gasification, and combustion. Among topics which attracted special attention were gas turbines and underground gasification. Sir Ernest Smith addressed a meeting on the training of chemists for the fuel industries. In Sections 10, 11 and 12 (Chemistry in Relation to Natural and Artificial Textiles, to Elastomers, Plastics, Glass and Ceramics, and to Metals) the predominant tendency was towards fundamental investigations as an aid to the solution of practical problems. The academic approach was typified by contributions on the properties of seaweed rayon (J. B. Speakman), deuterium exchange in cellulose (H. Mark), the theory of crystallization and plastic flow (Sir Lawrence Bragg), the intrinsic viscosity of polymer solutions (P. Debye), the effect of crystallization on the mechanical properties of high polymers (G. Gee), the network theory of rubber (W. Guth and H. M. James), sorption kinetics (R. M. Barrer), the thermodynamics of metallurgical extraction processes (H. J. T. Ellingham), and the electrochemical mechanism of corrosion (U. R. Evans). Section 13 (Chemical Engineering) held a symposium on educational aspects, as well as discussions on a variety of large-scale processes, including the production of hydrogen, oxygen, heavy water and toluene.

In addition to the section meetings, Congress lectures were delivered by L. Pauling on "Molecular Structure and Biological Specificity", Sir Henry Dale on "The Part of Chemistry in the New Therapeutics", P. Karrer on "Recent Advances in Organic Chemistry", A. Tiselius on "Recent Developments in Electrophoresis", L. Hackspill on "Calcium Carbide and its Reducing Properties", and by B. C. P. Jansen, who took as his subject "*Simplex non veri sigillum*".

The second, equally important function of the Congress, namely, to promote and extend the invaluable personal contacts between chemists of different countries, was well provided for. Delegates and members were entertained by the Government, the Royal Society, the Royal Institution, the Chemical Society, the Royal Institute of Chemistry, the University of London, Imperial Chemical Industries, the English Speaking Union and other bodies. There were two Congress dinners, one of which was attended by the Prime Minister and Mrs. Attlee. In proposing the toast of chemistry, Mr. Attlee said that the problem of the modern world was not how to make more advances in science, to which it owed so much, but rather, how to secure a world in which those advances could be made with safety. This indeed must have been the predominant thought of all those who took part in this Congress.

SEVENTEENTH INTERNATIONAL PHYSIOLOGICAL CONGRESS

THE Seventeenth International Physiological Congress was held in Oxford during July 21–25 under the presidency of Sir Henry Dale. It was attended by about 1,200 physiologists, including welcome delegates from the U.S.S.R. and China. The official programme was very heavy, for 350 communications, about seventy demonstrations and a number of films had to be compressed into three working days.

There were a number of excellent films, including one of hypothalamic stimulation by W. R. Hess, the isolation of a single nerve fibre by A. von Muralt, perfusion of the whole animal by I. de Burgh Daly, and colour films for teaching made with the help of Imperial Chemical Industries, Ltd., by J. H. Burn and F. R. Winton.

In earlier international congresses, it was intended that communications should be demonstrative and experimental, and memorable demonstrations have included one by Sherrington on the reciprocal innervations of antagonists, and another by Mering and Minkowski on the experimental production of diabetes. This year the demonstrations were interesting and competent, but not, perhaps, of the first importance.

For the communications, nine lecture theatres were in use simultaneously during the six sessions. This permitted the programme to be completed without trespassing on the time available for the all-important social activities, and their opportunities for personal contact.

A considerable number of communications arose from work undertaken with official encouragement in the War. Studies on respiration at high altitude, at high pressures of oxygen and carbon dioxide, explosive decompression, resistance to centrifugal force, resistance to high environmental temperature, all demonstrated the practical usefulness of physiological analysis.

Studies which were made possible by the development of new substances during the War, or which arose out of the care of war casualties, were on the whole of greater scientific importance. The application of di-isopropyl-fluorophosphonate to a variety of systems involving acetylcholine, and further controversy over the part played by acetylcholine in the transmission of the nerve impulse, the application of B.A.L. to the treatment of poisoning by arsenic and other metals, are good examples. Work on patients suffering from starvation, traumatic arterio-venous aneurysms and traumatic paraplegia has also been not unprofitable.

Perhaps the most important work reported, however, has been in independent research, in which, in Prof. E. G. T. Liddell's phrase, after seven years, members were showing an active post-inhibitory rebound. An outstanding paper was given by A. L. Hodgkin and A. F. Huxley, who suggested that during the rising phase of the action potential in nerve, the membrane becomes highly permeable to sodium ions, which then enter the cell. Potassium ions leave the cell during the falling phase and later restorative processes occur linked with energy-producing mechanisms. There was considerable indirect evidence in favour of this view. A theoretical treatment of the principal events in muscular contraction was put forward by A. Szent Györgyi, and provoked a vigorous discussion (see also p. 262).

The refinement of physical methods applicable to living organisms has progressed rapidly. Methods of measuring tissue fluid flow by radioactive helium, recording the contour of the heart by a precise radiographic and photo-electric method, continuous records of blood pressure in man by a condenser manometer, all provide powerful tools for work on the circulation. The clinical physiologists, A. Cournand, J. V. Warren, E. A. Stead, J. McMichael and E. P. Sharpey Schäfer, using cardiac catheterization, have demonstrated the similarities as well as the differences in the behaviour of the circulation in man and in anæsthetized animals.

The nature of the proteins of muscle and of the nucleus and its chromosomes has continued to occupy much attention. The central nervous system also was the subject of a large number of papers; but there were no outstanding advances in any of these fields.

The Congress accepted an invitation to Copenhagen for the Eighteenth International Congress, to be held in 1950, under the presidency of Prof. August Krogh.

On the last day, the University of Oxford conferred degrees of Doctor of Science on Profs. C. H. Best, H. S. Gasser, B. A. Houssay, August Krogh and A. Szent Györgyi.

GRASSLAND AND ANIMAL PRODUCTION

In July 1937 the International Grassland Conference was held in Great Britain, and the delegates examined closely the work and promise of the Aberystwyth nucleus, from which so much of the newer knowledge and philosophy of grassland management has spread. In the last week of June 1947, a further review of the activities of the Welsh Plant Breeding Station was made by members of the British Grassland Society and the Society of Animal Production at the first joint meeting of the two groups. This occasion, too, was given a minor international flavour by the representatives from countries overseas, who took the opportunity to refresh their contacts with workers in Britain; but, useful as this was, the greater significance of the meetings and visits lay in the interchanges of ideas and comments between those concerned on one hand with better grassland and, on the other, with better use of that grassland by the animal.

At first glance, there should be no divergence between the two aspects; clearly, however, there is. Moreover, there might appear to be a close parallel between the objectives of the animal husbandman and the agronomist: one aims to increase productivity by better nurture, better breeding, and a replacement of the less biologically efficient stock by those of greater and more reliable merit, the other at improving productivity of the plants by broadly similar means. Yet such a parallel would be deceptive as a representation of the past, and even present, courses of the two lines of endeavour.

During the last ten years great progress has been achieved in the development of plant-breeding methods and material. At all stages of the process, from the search for fresh material, its testing, experimental breeding, progeny-testing, and multiplication, to the treatment of seed, and the certification of stocks, as well as in the maintenance of proved stock plants or strains and in the trials of material from other sources in pure cultures and in mixtures, the techniques have advanced even under the difficulties occasioned by war-time shortages of personnel and equipment. The gardens and trial grounds of the Plant Breeding Station at Penglais, with the larger plots and field trials at Frongoch and the multiplication fields at Morfa Mawr, provided the background for a spectacular display by Prof. T. J. Jenkin and his colleagues of the use and application of the old and new methods—to the envy of the animal breeders, who, restricted by the numerical smallness, but physical largeness, of their material, have also to think in terms of populations.

The years of war have accelerated the spread of the selected Aberystwyth strains of grasses and of clovers into practical conditions of grassland establishment. The urge to increased production of British agriculture has given encouragement to ley farming, and the demand for seed of known origin has had repercussions in the seed trade, as well as on the administrative and routine activities of the staff of the Station. At the same time, the principles and methods of improving the swards of the higher and inherently poorer grazing lands, as developed at Llety-Evan-Hen and the Cahn Hill Improvement Scheme, have been given a wider extension to other hill areas, to the enhancement of stock production, as was described by Mr. Moses Griffith and Prof. W. Ellison at the separate meeting of the Society of Animal Production. The prospect of the early discontinuation of the Cahn Hill work is regarded with concern by both Societies, the members of which recognize the important role of the hill farming areas in the maintenance of a healthy and balanced stock-raising industry in Great Britain.

Though somewhat envious of the technical opportunities and material advantages offered to the plant breeders, the stock men were none the less comforted. They found themselves, for example, on familiar though not so clearly signposted country in noting such matters as the variation among the progeny from selected parents and strains, the differential responses of varieties and strains under a common environment and changed behaviour in other environments, the range in maturity, the effects of length of day on reproductive organs, the handiness of 'indicator' characters (but not of necessity their feasibility as measures of performance), change or 'degeneration' in the later generations of stocks grown on in other areas, or even the different potentialities and performances of 'pedigree' and 'commercial' strains. There should be much common ground here for future co-operation in study and discovery of principles, for example, in wedding the ecological approach to the genetical, to enlighten the limits of selection in one environment to meet the demands and suitabilities in another.

The present divergence of views occurs with regard to purpose and method. The emphasis in the grassland work appears, to the animal husbandman, to be on the sward, and its management to the benefit of the sward. The increased productivity of swards, as swards, which can emerge from suitable seeds mixtures, sown under favourable conditions of soils and cultivations, with appropriate fertilizer treatments and apt grazing and cutting, is clearly demonstrable and has, in fact, been often and well demonstrated.

The possible marked extension of the grazing season and the expanded opportunities for conservation of the surplus product of highly valuable protein foodstuff affords hope of a greatly enhanced, even revolutionary, level of animal production. Sir George Stapledon, in a noteworthy address, suggested a ten-year plan for more livestock to utilize his envisaged 9 million acres of leys and 4 million acres of permanent grass against the present 10 million permanent and 3 million leys—and asked for guidance as to numbers, kinds and quality for this target. Yet he, adding his emphasis to that offered by many of the demonstrations, recognizes the extraordinary niceties of reaction of the plant strains and mixtures to all points of management, and implied doubts whether a suitable technique of testing the absolute value of the pastures can be derived unless they are grazed at different intensities of grazing, and admitted that at times, for suitable conditions of conservation of surplus growth, drastic treatment by cutting has to be adopted.

The main use of grassland is for grazing—but that platitude over-simplifies many of the real issues. Experimentally it may justify using the grazing animal to measure pasture productivity in terms of live-weight increase or milk yield, which terms achieve an apparent validity since they are involved in economic or practical returns. However, it has also been clearly shown that grazing in itself is a powerful factor in altering the composition and 'utility' of the grazed pastures. Pasture management has long been realized to involve control of the biotic factor, but from the animal physiologist's point of view the nature of this complex influence is by no means sufficiently understood for it to be used as anything more than a very general and indirect measure of productivity. This is especially the case when there is a dearth of experimental evidence on the important question as to how far the very conditions of restraint, implied in using animals to graze small plots under trial conditions, themselves affect the animals' reactions, behaviour, growth, development and output, as of live-weight.

The ultimate purpose is to translate experimental results into farm practice. This introduces another set of, as yet, imponderable factors. The field is a unit only in so far as it is part of the farm; the grazing animal also is part of a herd or flock. For the farm as a whole—even for the country as a whole—the supply of winter feed is the limit to production; to widen this restriction, forage crops and conserved grassland in the form of silage or dried grass offer prospects of greater development. But a better and more efficient alternative in present circumstances, in Dr. John Hammond's view, might be to utilize the high production of the summer months for cheaper summer fattening, and to conserve and store the animal product rather than the grass. Again, the numbers of animals on a farm are relatively fixed over long periods; under practical conditions, especially in these days of self-contained dairy herds, the farmer cannot arrange the timing or intensity of grazing to meet those niceties of management which the grassland expert dictates as optima for the good of the sward. As Prof. W. C. Miller suggested, the complex situation of stocking and stock-management may require more complex mixtures of grazing constituents to provide pastures which can be practically mismanaged with safety, rather than a multiplicity of mixtures and treatments, each needing specific control to evoke their best response.

So long as conditions vary from farm to farm, field to field, and season to season, the principles of stock and grazing management must be allowed very flexible application. Even those of rotational grazing, with subdivision of the areas into smaller units, particularly in so far as it involves the human factor of judgment of pasture productivity, are not fully understood, as the plots at the College Farm at Nantcellan show. The formal and informal discussions at these meetings proved that a great deal of endeavour remains to be applied to the problems of the pastures we grow, the uses to which they can be put, and our methods of using them—and that any mutually exclusive interpretation of the results of experiment and observation by animal and grassland specialists is no longer admissible.

J. E. NICHOLS

THE RADIATIONS FROM THE EARTH'S ATMOSPHERE

IN the latitudes of London, Paris or Washington the appearance of an aurora borealis is somewhat infrequent and finds few investigators prepared with equipment for detailed observation. Most of the work on the location and spectra of aurora has therefore been done at such places as Tromsø, which are within the main auroral belt: our knowledge of the phenomenon is mainly due to Størmer and Vegard, and their collaborators. The principal progress has been achieved in the present century, and especially in the last ten or fifteen years. It has only been rendered possible by the rapid general advances in physical techniques and equipment.

During the first quarter of this century, it began to be recognized that at all latitudes the night sky is appreciably luminous even in the absence of the moon. This effect is partly due to radiation from the stars, both those individually visible and those much more numerous stars too faint to be detected by the unaided vision; the zodiacal light, which is of the nature of scattered sunlight, also makes a contribution. But the major part of the luminescence originates in the atmosphere itself: its spectrum shows a complex set of emission lines and bands against a continuous background. The intensity is very low, so the observational work is extremely difficult. Slipher, who was among the first to study the spectrum of the night sky light, discovered that a permanent component of it is the famous green line previously known to be prominent in the auroral spectra. Rayleigh, who used characteristically simple methods, devised and carried out, partly with the aid of observers overseas, a many-sided programme of observations. By means of filters he distinguished three different spectral regions and studied their geographical distribution and their temporal variations. He even measured the absolute intensity of the green line: the number of photons he found to be emitted in a square centimetre column of atmosphere is about 2×10^8 per sec. This remarkable pioneer work gave results of lasting value.

The problem of the identification of the green line was solved by McLennan and his colleagues who, in the years 1925–27, showed that it arose from atomic oxygen and is due to what is called a forbidden transition—that is, one that violates the normal selection rules and is only possible because of their approximate nature. Now the emission of the green-line radiation does not bring the oxygen atoms involved to their ground-state; it instead brings them to the lowest excited state. In final passage from this state, radiation may be emitted corresponding to certain red lines. These have now been found both in the night sky and auroral spectra. It is possible that the forbidden lines of atomic nitrogen are also present.

More recently, in 1938, there came from France the astonishing news that sodium occurs in the high atmosphere in the free atomic form. Proof for this was provided by the identification of its characteristic yellow line (or rather doublet).

In addition to the atomic lines a large number of bands appear. Those in the spectra of auroras can be ascribed mainly to neutral and singly ionized molecular nitrogen. Much work has yet to be done on the interpretation of the night sky spectrum; but it seems probable that the principal contribution to the visible region is from neutral molecular nitrogen, and the principal contribution to the ultra-violet region is from neutral molecular oxygen: the bands of singly ionized molecular nitrogen seem to be normally absent. An interesting discovery, made in 1942 by Herman, Herman and Gauzit, is a remarkably strong emission in the infra-red region: its identification is still in doubt.

A growing number of highly skilled observers have been drawn into this branch of research and have obtained many unexpected and varied results. These have aroused the interest of geophysicists, astrophysicists, laboratory spectroscopists, theoretical physicists, radio scientists, chemists, and mathematicians. One manifestation of this interest was an international conference on the "Emission Spectra of the Night Sky and Auroras" organised under the auspices of the Gassiot Committee of the Royal Society and held in the Society's rooms at Burlington House, London, during July 7–10.

The Gassiot Committee is charged with the supervision and planning of a long-term programme of research on the radiation in the atmosphere and on related phenomena. This commitment was undertaken at the request of the Air Ministry (on the advice of the Meteorological Research Committee). Financial aid is given by the Ministry. The initiative in proposing the conference was taken by Prof. H. S. W. Massey, chairman of one of the sub-committees appointed by the Gassiot Committee to deal with different sections of the general programme.

The conference was attended by guests from Belgium, France, Norway, Sweden and the United States, and by many from the British Isles. Russian scientific workers have done much work in the field concerned, but none was able to be present: the Embassy, however, sent an observer. The papers read at the conference will be published by the Physical Society in the next issue of its "Report on Progress in Physics". Here only an outline of the ground covered will be attempted.

The best recent observations of the night sky spectrum have been made in France and the United States. Papers describing the results were contributed by G. Dejardin, J. Dufay, Tcheng Mao-Lin, A. and E. Vassy, R. Grandmontagne, C. T. Elvey and E. O. Hulburt. There was considerable discussion of the altitude of the luminous region, which is still very uncertain. Much attention was given to the special character of the spectrum at twilight, when the negative bands of nitrogen, the red lines of oxygen, the yellow doublet of sodium and possibly other components are enhanced. A. Kastler described work by J. Bricard and himself on the polarization of the light of various atomic lines using a very simple polariscope due to Savart and improved by Lyot. The green oxygen line was found to show less than 3 per cent polarization—a result to be expected from theory, but contradicted by recent measurements in the U.S.S.R. D. Barbier, R. W. B. Pearse and others discussed the identification of the spectral components. A great deal of time was devoted to the complex and fascinating task of explaining the cause of the emission. D. R. Bates, H. S. W. Massey, and M. Nicolet contributed papers relating to this problem. It seems probable that the emission is due in part to the dispersion of the energy stored up by the dissociated oxygen (and perhaps also nitrogen) formed during the day: recombination of the charged particles in the ionosphere will play a minor part. Consideration has also to be given to the suggestion that incident particles may have to be invoked to explain such effects as the irregularity of the light. Much remains to be elucidated. P. M. S. Blackett presented an interesting paper on the possibility of cosmic rays making an observable contribution to the continuum through Cerenkov radiation.

Recent observational work on auroras was reported by G. Kvifte (on behalf of L. Vegard) and by R. Bernard. Confirmation was given to the suggestion that hydrogen and helium may be present. An important new analysis of the spectrum was given by M. Nicolet. K. G. Emeléus read a paper sent by J. Kaplan describing laboratory experiments on the reproduction of the characteristic emissions.

It is generally accepted that auroras are due to the action (direct or indirect) of charged particles guided pole-wards by the earth's magnetic field. However, the nature, origin and energy of these is still the subject of controversy. Widely different views were expounded in papers by H. Alfvén, S. Chapman, and F. Hoyle.

One session of the conference was devoted to a discussion, led by R. W. Ditchburn, on the instruments and techniques of observation. E. O. Hulburt gave a valuable account of the work being done in the United States on the exploration of the upper atmosphere by means of rockets.

D. R. BATES

OBITUARY

Prof. J. Perner

THE death occurred at Prague, on June 9, of Dr. Jaroslav Perner, professor of palæontology at the Charles University. Born at Tynec-nad-Labem on March 28, 1869, Perner claimed to be a pupil of the French geologist, Joachim Barrande (1799–1883), in whose footsteps he followed by continuing the investigation of the fossil fauna of the Silurian and Devonian rocks of middle Bohemia. His studies were incorporated in various publications, including "Système silurien du centre de la Bohême" and a work of four volumes entitled "Études sur les graptolites de Bohême". Most of his other publications were in Czech or German.

Early in life Perner came to England and spent a period in the 'nineties at Mason College (afterwards the University of Birmingham) working under the late Prof. Charles Lapworth. J. G. F. D.

NEWS and VIEWS

The Royal Society of Arts

H.R.H. THE PRINCESS ELIZABETH has graciously accepted the invitation of the Royal Society of Arts to become its president. The Royal Family has been closely connected with the Royal Society of Arts for more than a hundred years. Prince Albert became the Society's president in 1843, and in that capacity initiated the Great International Exhibition held in Hyde Park in 1851. Other Royal presidents have been Their Royal Highnesses the Prince of Wales (later King Edward VII), the Prince of Wales (later King George V) and the Duke of Connaught.

The British Museum (Natural History)

Sir Clive Forster-Cooper, F.R.S.

SIR CLIVE FORSTER-COOPER will retire from the post of director of the British Museum (Natural History) on September 30, after ten arduous years of office, and a much longer period spent in the service of museums and libraries. His active interest in museum problems goes back to the days when, as a young man, he studied in the American Museum of Natural History under the late Prof. H. F. Osborn; but he was not connected with a museum in an official capacity until some years later. In 1914 he became superintendent of the University Museum of Zoology, Cambridge, and immediately began a much-needed reorganisation. By dint of drastic pruning and rearrangement, he transformed an old-fashioned teaching collection into a modern museum well adapted to the changed conditions after the First World War. During this period, Mr. Forster-Cooper was elected a syndic of the FitzWilliam Museum, and also to the University Building Syndicate of which he ultimately became chairman. The scheme for a new university library had its origin in a suggestion which he made soon after his election to the latter body.

When the Principal Trustees appointed him director of the Natural History Museum in 1938 he began to replan the exhibition galleries, and here his long experience in Cambridge was of great value. For the first year all went well, and important experiments in exhibition technique were carried out; but the international situation gradually became more threatening, and early in 1939 all these plans had to give way to others for the evacuation of the collections and libraries, and to general precautionary work. These tasks were scarcely finished when air raids on London began. In quick succession the roofs were burnt off the Herbarium and the Shell Gallery, and further damage was done to the building by high-explosive bombs. All the time that the Director was dealing with the day-to-day hazards of war, he was laying his plans for the future. They were summarized in a memorandum which was adopted by the Trustees as a basis for future action, although any hopes of their immediate realization were dashed when a flying bomb, which exploded in the Cromwell Road in July 1944, wrecked almost the whole of the interior fittings in the front galleries of the Departments of Geology and Zoology. After the War he supervised the return of the libraries and collections, and the reopening of those parts of the ground-floor of the Museum still fit for use. His services received official recognition with the award of a knighthood in the New Year Honours of 1946.

Mr. N. B. Kinnear

MR. NORMAN BOYD KINNEAR, who has been appointed to succeed Sir Clive Forster-Cooper as from October 1, was educated at Edinburgh Academy and Trinity College, Glenalmond. After acting for two years as an assistant, on a voluntary basis, in the Royal Scottish Museum, he became for twelve years curator of the Bombay Natural History Museum and from 1908 until 1919 was assistant editor of the important Bombay Natural History Society's *Journal*. In 1920 he joined the staff of the British Museum as an assistant keeper, and after a period as deputy keeper was, in 1945, appointed to the keepership of the Department of Zoology.

Mr. Kinnear's time in India gave him the opportunity of much work in the field and of acquiring a wide knowledge as a field naturalist of the living fauna of the country in general in addition to his main line of work as an ornithologist. Most of his published work, chiefly in the *Ibis* and the *Journal of the Bombay Natural History Society*, deals with birds, especially the avifauna of the East, as, for example, the birds of the Eastern Ghats, of central south Arabia, Chinese Turkestan, north-east Burma, and south-east Tibet among others.

During the War, in addition to the struggle of keeping the Department of Zoology going under very adverse circumstances, he did signal service first in helping with the evacuation of the Museum's collections to safer places than London and then, after the War, in the complicated business of their return, unpacking and resettlement, work which is still in progress and in present circumstances requires much thought and planning. Mr. Kinnear in 1943 was elected president of the British Ornithologists' Union and is the present chairman of the British Section of the International Committee for Bird Protection.

Science in Scotland

UNDER the title "Science in Scotland", Dr. W. P. H. Wightman gives a very readable account of the development and work of the Rowett Research Institute in Animal Nutrition, the Macaulay Institute for Soil Research, the Moredun Institute of the Animal Diseases Research Association, the Institute of Animal Genetics, the Hannah Dairy Research Institute, the Torry Research Station for fishery research and the Scottish Society for Research in Plant Breeding ("Science in Scotland: the Work of the Scottish Research Institutions", by Dr. W. P. H. Wightman. Published for Scottish Convention. Pp. 56. Stirling: Eneas Mackay, 1947. 2*s*. net). Some of the achievements of these research institutions are indicated, while in a final chapter the foundation of the Seaweed Research Association is noted and the establishment of a Scottish Forest Products Research Station and of a Sea Loch Development Association is suggested. Dr. Wightman is not convinced as to the advisability of separate Scottish institutions for most manufacturing traditional industries, and suggests that the principles guiding the establishment of distinctive Scottish research institutions should be in the main the development of predominant Scottish resources; the special problems arising out of Scottish customs and conditions; the need for economy in time for consultation even at the cost of duplicating overhead charges; and the appeal to national enthusiasm and local interest.

Education in the Royal Air Force

The Secretary of State for Air has announced that the Air Council has decided to set up an Educational Advisory Council for the Royal Air Force with the following terms of reference: "To keep under review the educational policy for the Royal Air Force and to advise the Secretary of State for Air on such matters connected with education in the Royal Air Force as they think fit and upon any educational questions referred to them by him." The following will, in addition to representatives of the Ministry of Education, the Scottish Education Department, and the Ministry of Labour and National Service, serve on the Council: Dr. Keith A. H. Murray, rector, Lincoln College, Oxford (*chairman*); Mr. Harold E. Clay, president, Workers' Educational Association; Miss M. C. Glasgow, secretary-general, Arts Council of Great Britain; Mr. Ronald Gould, general secretary, National Union of Teachers; Miss V. Holmes, member of the Council of the Women's Employment Federation; Mr. J. C. Jones, director of education, the Polytechnic, Regent Street, London; Air Chief Marshal Sir Edgar Ludlow-Hewitt, R.A.F. (retired); Mr. H. Morris, chief education officer, Cambridgeshire; Mr. J. H. Nicholson, principal, University College, Hull; Dr. D. R. Pye, provost, University College, London; Mr. W. E. Williams, director, Bureau of Current Affairs; Mr. J. F. Wolfenden, headmaster, Shrewsbury School.

Science in the New India

The presidential address of D. N. Wadia at the thirteenth annual general meeting of the National Institute of Sciences of India, after referring to the ten-acre site which the Institute has acquired for its building and to the organisation and expansion of its secretariat and mentioning the formation of two strong committees to advise the Government on research in the Indian academies, institutes and universities, was devoted to a discussion of the role of science in building the new India. Science, in its comprehensive application to problems of human existence, is the one agency which, in the transition period through which India is passing, will lift the country out of its abnormal economic and industrial depression and put it on the high road to progress and human welfare. The first requisite is that India should align her scientific organisation with that of the progressive countries of the world, and Mr. Wadia welcomed the multiplying ties of India's leading men of science with representative men of science of Great Britain, the United States, the U.S.S.R. and the rest of Europe, referring in particular to the value of the United Nations Educational, Scientific and Cultural Organisation, of the international scientific liaison offices, and to the work of the Royal Society Empire Scientific Conference and of the Commonwealth Scientific Official Conference.

Discussing India's response to the latter Conference, he insisted that the unhealthy distinction between official and unofficial scientific workers must go, and that the universities, private research institutions and societies will more and more be the spearheads of scientific progress. Striking progress has been made in the last few years in irrigation and hydraulic research, and the Government during the last year has sanctioned large-scale operations on several hydro-electric power, irrigation and reservoir projects, giving high priority to three large projects connected with the harnessing of the Damodar, the Mahanadi, and the Kosi Rivers. A committee formed under the Board of Scientific and Industrial Research has drawn up a long-range programme of research in nuclear physics and artificial creation of atomic particles to be carried out at the Tata Institute of Fundamental Research and at the Palit Laboratory, University of Calcutta. In regard to minerals, the Government is taking steps to bring under Federal control those of strategic importance and was convening a Conference to formulate a mineral policy for India and to establish executive machinery for guiding production, conservation and utilization of the mineral products mined.

Winchester City Museums, 1847–1947

July 15 of this year marked the centenary of the Winchester City Museum, and the curator, Mr. Frank Cottrill, has appropriately marked the occasion with a short account of its history and growth. Established in 1847 as the Hampshire Museum, this institution set out to save for posterity collections illustrative of local history, antiquities and natural history which might otherwise have been "lost or disregarded, retained in private hands, or have found their way to distant exhibitions". For a time the Hampshire Museum flourished on private donations and subscriptions, but later, as has been the case in so many of the local museums founded during or near the same period, this form of support was not maintained. The nature of the collections, however, and the increased use of the Museum by the public, fully justified the upkeep of the institution. Accordingly, in 1851 it was transferred to the custody of the Winchester Town Council, under the government of which it remains at the present time. A Museum Committee was appointed, and the institution from then on became known as the City Museum. In this way was the safety of the Winchester collections safeguarded. Originally housed in the Hyde Abbey schoolroom, the collections were removed first to part of the old jail in Jewry Street, then to the top floor of the Guildhall, and finally, in 1903, to the present building in the Square. Prior to that, in 1898, the Museum was extended by the opening of the Westgate as a second museum. This was largely due to the interest and beneficence of Alderman W. H. Jacob, a keen local historian. A beautiful old building dating from the thirteenth century, but unfortunately overshadowed by modern constructions entirely out of keeping, Westgate to-day houses, among other things, the City's famous collection of weights and measures ranging in date from the twelfth to the eighteenth centuries. Here, also, is preserved the Winchester moot-horn of about A.D. 1200.

Mr. Cottrill's proposals for the reorganisation of the Collections concern mainly the very overcrowded City Museum, and he rightly stresses the need for the relegation to store of much of this material if the Museum is to illustrate effectively and teach the early history and subsequent development of the town and county. (Storage in this connexion does not mean that collections will become inaccessible to students and others specifically interested in them.) There is an ever-growing tendency for the smaller museums to specialize in the interests of their own particular region, and this, without doubt, is the only way in which the majority of them can become effective units in the community they serve. The curator of the Winchester Museums clearly wishes for development along similar lines, and if his plans are adopted the Winchester collections, already well known to students at home, should attract to "the capital city of Alfred and Canute" visitors from farther afield. In the reorganised Museum, he also points out the need for a printed guide and the maintenance of a small reference library. These are matters which are often overlooked by an authority responsible for an otherwise good museum service.

Diseases of Flax

In February 1943 the Minister of Agriculture (Eire) set up a Flax Development Board for the purpose of encouraging flax production. Owing to the stimulus of better prices and a guaranteed market for flax under war-time conditions, the area cropped in 1942 had already risen to 18,552 acres compared with only 4,123 acres in 1939. The Board's activities resulted in a further sharp rise in area under flax, the peak being reached in 1945 when just over 32,800 acres were grown. Such intensive cultivation inevitably introduced fresh problems, and diseases and pests became more prevalent and assumed greater significance. At the request of the Board, Dr. R. McKay has prepared a bulletin, "Flax Diseases" (price 5*s*.), which will meet a long-felt want. Though the information contained in this publication does not claim to be new, it has hitherto been so scattered in various scientific and agricultural journals as to be quite inaccessible to the ordinary farmer, flax inspector or mill-owner. The diseases are grouped according to the causative factor, whether it be fungus, parasitic flowering plant or non-parasitic agent, such as weather conditions. Insect pests are also included. The symptoms are clearly described and illustrated in each case and control measures suggested where possible. References are supplied for those who wish for more detailed information, and a useful glossary of scientific terms included.

Pacific Science

The University of Hawaii has long been an active centre for scientific investigations in the Islands, as has the Bishop Museum, Honolulu. This work will now be intensified as the result of the wise co-ordinating policy laid down by the National Research Council of the Pacific Science Conference at its meeting in Washington in June 1946. Partly as a result of this, the University has undertaken to sponsor a new quarterly journal, entitled *Pacific Science*, which is devoted to the furtherance of biological and physical sciences in the Pacific region. Two numbers of this publication, those for January and April, are now to hand and they are excellently printed, illustrated and produced. The personnel of the editorial board covers a wide range of subjects and, interestingly enough, the editor-in-chief is the head of the Department of English.

Each number consists of sixty-eight pages, very similar in size to *Nature*, and is provided with an attractive coloured cover on the inside of which are useful instructions to authors for the preparation of papers. The two numbers include papers on forestry, geology, ornithology, parasitology, mycology, botany, an apparatus for chloride and oxygen determination for pond waters in the field, and the Tsunami, that long-period gravity wave associated with volcanic disturbance, one of which in April 1946 created such havoc in the Islands. No. 1 contains, as a sort of appendix, the interesting recommendations of the National Research Council referred to above, and No. 2 similarly reviews the facilities for research in the Islands provided by more than twenty government or private institutions. The subscription to *Pacific Science* is 3.00 dollars per annum, payable to the Office of Publications, University of Hawaii, Honolulu 10, Hawaii. With the extraordinary wealth of material available not only in the Islands themselves but also in the rest of the Pacific group which will be included in its scope, the journal should have an assured future, and we wish it every success.

Royal Commission for the Exhibition of 1851

The report of the Board of Management, Royal Commission for the Exhibition of 1851, dated December 1946, covers the seven years since July 25, 1939 (from the Commission, 1 Lowther Gardens, London, S.W.7). The award of industrial bursaries was discontinued on the outbreak of war, and in July 1946 only seven of the twenty-nine bursars appointed in 1939 and none of those appointed earlier remained on the books. While the Board has already given 'rehabilitation' grants to a few bursars who wished to complete their industrial training and who have been unable to obtain assistance for this purpose under the regulations of the Ministry of Labour and National Service, the Board has resolved to suspend the scheme for the present and to re-examine the position when industry in Great Britain and its pattern of recruitment have acquired a more definite pattern. The Board has, however, increased to £500 a year the value of the post-graduate scholarship in naval architecture, and new regulations have been prepared which will open the field to candidates from all university institutions in the United Kingdom which have departments of naval architecture or engineering science. The scholarship will be tenable normally for two years, and the conditions have been designed to make it attractive to the trained research worker. Arrangements have also been made for the partial resumption of the activities of the British School at Rome, and discussions on the re-development plan for the South Kensington estate have been renewed. Certain modifications in the plan have become necessary in view of the urgent importance of extending the Fuel Technology Laboratory already on the site to the west of the Royal College of Music, and which the Imperial College of Science and Technology had originally proposed to relinquish.

The Board of Management also endorses the views expressed by the Science Scholarships Committee in a separate report covering the proceedings of the Committee since April 1939. The Committee, reviewing the working of the Science Research Scholarships Scheme between the two Wars, agrees that no major change is needed in the general principle of the overseas scheme, but recommends that the value of the scholarships should be increased to £350 a year with a £50 annual grant for fees, and that a second annual scholarship should be allocated to India. On the other hand, it recommends that the value of the senior studentships should be increased to £500 a year with a possible extra £50 for expenses, but that the number of annual awards should be reduced from five to four. The additional expense of giving effect to these recommendations is estimated at rather more than £3,000 a year. Particulars are included in the report of the appointments made for 1946 in accordance with these recommendations; although normally only ten overseas scholarships are awarded, an additional scholarship has this year been granted to New Zealand in view of the exceptional merits of the two candidates put forward.

Decay of Negative Mesons in Matter

A VERY drastic change in the present conception of the interaction of mesons with atomic nuclei was suggested by Fermi, Teller and Weisskopf[1] as a result of the experiments by Conversi, Pancini and Piccioni[2], who observed the behaviour of positive and of negative cosmic ray mesons coming to rest in iron or graphite. They find that in iron, disintegration electrons are observed only for positive mesons. According to Tomonaga and Araki[3], this is to be expected because negative mesons—in contrast to positive ones—after being slowed down can approach the nucleus and be absorbed by it in view of the strong interaction postulated by Yukawa to explain nuclear forces. In graphite, on the other hand, decay electrons were observed from both positive and negative mesons. Fermi *et al.* concluded that this was in sharp disagreement with expectation, because according to their estimate it takes only about 10^{-12} sec. until a negative meson in a solid reaches its lowest orbit, from which it should be captured by the nucleus in less than 10^{-18} sec. Since the natural decay time is only 10^{-6} sec., they conclude that from negative mesons no decay electrons should be expected, in contrast to the experimental evidence in graphite.

To calculate the slowing down of mesons with an energy below 2,000 eV. (that is, with smaller velocity than that of the electrons of the solid) these authors use a Fermi gas of free electrons as a model of the solid. I wish to point out that, for non-conductors in any event, this model does not seem to be adequate, and that a better model might be obtained in this case by using an assembly of electronic oscillators as a model of the solid. That this model leads to results entirely different from the free-electron model follows from the fact that a point charge e moving with constant velocity v transfers energy proportional to v^2 to free electrons, but proportional to exp $(-a\omega/v)$ to an oscillator (frequency $\omega/2\pi$, closest approach a) if $a\omega \gg v$. In this connexion a result obtained by Pelzer and me[4] may be of interest. A point charge moving with constant velocity v through a dielectric with dielectric constant ε having a proper frequency $\omega/2\pi$ transfers to it energy at a rate

$$\frac{\varepsilon - 1}{\varepsilon}\,\frac{e^2}{a_0}\,\omega\gamma e^{-2\gamma}, \text{ approximately,}$$

if $\gamma = a_0\omega/v \gg 1$. Here a_0 is of the order of the zero-point amplitude of the oscillators of which the dielectric is composed. Taking $e^2/a_0 = 10$ eV., $\omega = 10^{16}$ sec.$^{-1}$, $(\varepsilon - 1)/\varepsilon \simeq 1$, and $\gamma = 15\ (13)$ (= ratio of velocities of electrons and mesons of equal energy) yields a rate of loss of only 10^5 (10^7) eV. per sec.

No doubt this crude method of calculation requires considerable improvement to obtain quantitative results. It serves, however, to show (i) that the model of oscillators leads to times of slowing-down which are larger by many orders of magnitude than those of a free-electron model, and (ii) that the rate of loss of energy is a quantity which (in view of the exponential factor) is very sensitive towards variation of $a\omega/v$ and may lead to slowing-down times just above or below the decay time of mesons. It seems possible that even in metals a modification of the method used by Fermi *et al.* might be necessary, taking account of the screening of the charge of the moving meson.

Therefore it seems that the drastic change suggested by Fermi, Teller and Weisskopf[1] need not be contemplated at present, but that very detailed calculations will be required to make predictions about the slowing-down time of mesons.

I wish to express my thanks to my colleagues of this Laboratory for interesting discussions.

Definition of Nuclear Quadrupole Moments

THE quadrupole moment of a nucleus is usually defined[1] as "the quantity $(3z^2 - r^2)_{Av}$, where the average is taken over the nuclear charges for the state which has the maximum component of spin I in the z direction". This seems to imply that the average is taken over all the protons in the nucleus; but if this be so, it is impossible to reconcile the measured values of nuclear quadrupole moments quoted by Mattauch[2] with current ideas of nuclear size. Thus the quadrupole moment of tantalum is reported to be 6×10^{-24} cm.^{2}, which seems incompatible with a nuclear radius of about 9×10^{-13} cm. It seemed desirable, therefore, to examine carefully the derivation of the measured values.

All the quadrupole moments so far measured have been determined spectroscopically by analysing the deviation of the hyperfine structure from the interval rule. In all cases the calculation has depended ultimately on the theoretical work of Casimir[3]. Reference to Casimir's essay reveals that he defines the quadrupole moment as $Q = \int\rho(3z^2 - r^2)d\tau$, where ρe is the charge density of a volume element $d\tau$ and the integral is taken over the whole of the nucleus. Casimir calls this an average and writes it $\overline{(3z^2 - r^2)}$; but the use of the term 'average' in this context appears to have caused some confusion, for the following reason. If the quadrupole moment is regarded as due to a single proton, the remaining protons being assumed to have a spherically symmetrical distribution and therefore contributing nothing to the integral, then Q as so defined is the average value of $(3z^2 - r^2)$ for that proton. On the other hand, if each proton in the nucleus is regarded as contributing to the quadrupole moment, then the average value of $(3z^2 - r^2)$ over all protons is Q/Z, where Z is the total number of protons. Thus each of the quantities Q and Q/Z can, with some justification, be called an 'average' of $(3z^2 - r^2)$, depending on the system over which the average is taken. If one bears in mind that the quantities which have been measured experimentally are the values of Q, and not of Q/Z, they are seen to be of the expected order of magnitude.

It should be pointed out that whereas most writers on the subject adopt Casimir's convention in calling Q the 'average', this is not universally so. For example, Feather[4] explicitly defines the quadrupole moment (which he denotes by q) as the average over all protons, and in support of his definition states that the quadrupole field is proportional to Zq. However, the experimental values which he quotes are values of Q, so that these should be divided by Z to conform to his definition.

Probabilities of Magnetization

IN an earlier analysis of the B—H curves of polycrystalline iron it was shown that a simple 'trichotomy' of the steep part of the curves could lead to useful estimates of the quantitative distribution of operative lattice orientation along any given direction in polycrystalline sheet material[1]. Subsequent work was directed towards correlating such estimates with directional measurements of Young's modulus[2]; and it has been found that while the general trend of agreement is unmistakable, there is a consistent tendency for the trichotometrical method, when applied along the rolling direction, to yield a modest over-assessment of the operative percentage of [100] orientation.

The most likely causes of a systematic discrepancy of this kind would appear to be: (1) that there is a deficiency in the previously adopted conventional assumption that in the demagnetized state there will exist an equivolumetric distribution of domain magnetization along each of the six possible [100] crystal directions of easy magnetization; and (2) that the original approximation made no provision for the inevitable overlapping between the 'easy' reversals in one crystal-group and the 'hard' reversals in another.

An attempt has therefore been made to arrive at a sounder physical basis for the concept of trichotomy, and at the same time to gain further insight into the actual build-up of the technical magnetization curve, by postulating that the 180° reversal component of the steep part of the curve (for polycrystalline iron) will represent the summation of three probability-integrals, one for each of the idealized [100], [110] and [111] crystal-groups; and that each of these three integrals will satisfy a relationship of the form

$$\mu_d = \mu_{dm} \, . \exp\left[-b\left\{1 - (H/H_m)\right\}^2\right], \quad . \quad (1)$$

where μ_d is the differential permeability; μ_{dm} is the maximum value of μ_d; and b is a 'variance' factor or a 'distribution index' which will reflect, for any given crystal-group, the manner in which the achievement of 180° reversals is distributed about some characteristic 'mode' H_m of the critical field strength.

This revised treatment will clearly lead to a general relationship of the form

$$B = \mu_n H + \Sigma\mu_{dm} \int_0^{H \leqslant 2H_m} \exp\left[-b\left\{1 - (H/H_m)\right\}^2\right] dH, \quad (2)$$

where B is the externally measured magnetic induction, and μ_n is of the same order as the initial permeability μ_0. For iron and iron-silicon alloys, the summation term will comprise the areas generated by equation (1) for each of the three idealized crystal-groups. In equation (2), the $\mu_n H$ term will ordinarily be relatively small.

Investigation along these lines has indicated that this method of synthesis can lead to consistently improved and close agreement with observation up to the 'knee' region of the magnetization curve, that is, up to the point at which 180°-reversals are expected to be substantially completed[1]. A detailed discussion of its apparent applicability to a variety of experimentally induced conditions is in course of preparation for later publication, and the present communication is being submitted because the general picture which presents itself seems to provide an explanatory background for the peculiarly 'peaked' K_d curves recently recorded on certain types of ferromagnetic wire[3]. It will readily be seen that the summation term of equation (2) is fully competent to take charge of sharply segregated inhomogeneities of magnetization such as would result from the existence of markedly differing 'phases' in a ferromagnetic specimen; each phase will be expected to behave in accordance with its own 'probabilities', with resultant irregularities in the observed K_d curve. It is also clear that the physical basis of the treatment is in complete harmony with the expressed view that the irregularities observed "represent 180° reversals of demagnetized domain orientation of magnetization at values of H corresponding to the critical value of H_0 for different ferritic combinations."[3]

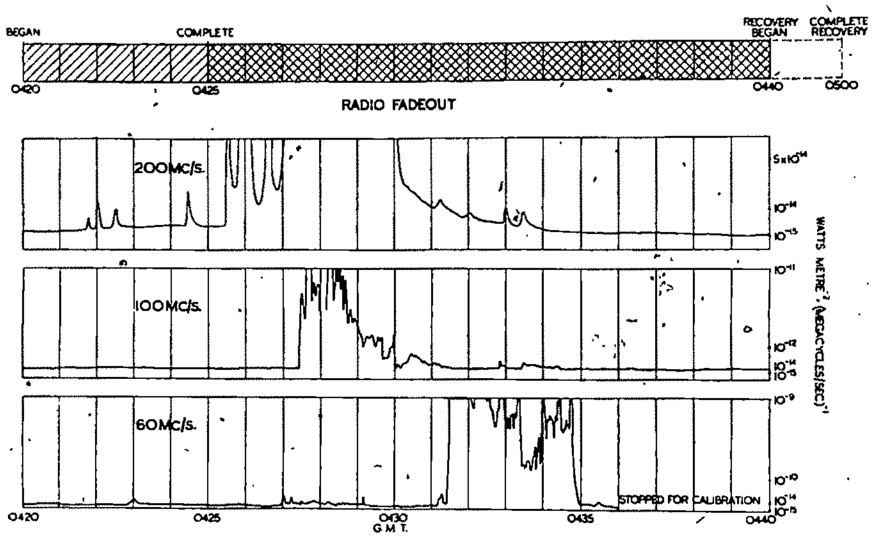
Relative Times of Arrival of Bursts of Solar Noise on Different Radio Frequencies

IT is becoming recognized that on metre wavelengths solar noise from the disturbed sun is characterized by the occurrence of sudden large increases in intensity of a duration of several seconds or minutes. Bowen[1], of this Laboratory, has reported that these increases of intensity are not necessarily coincident in time or shape when observed on different radio frequencies. The present communication describes observations, chiefly during July and August 1946, of the relative times of arrival of such bursts on 200, 75 and 60 Mc./s., with a few observations on 30 Mc./s. For each frequency a separate receiving system, actuating its own recording meter, was used. Loud-speakers were also connected giving aural confirmation of the recorded data.

Three main conclusions can be drawn from these observations:

1. *Lack of correlation between most bursts.* First and most important, the majority of the intensity variations, particularly the smaller ones, show no correlation with those on other frequencies. This supports a hypothesis that the noise on different



Large outburst of March 8, 1947

frequencies normally originates in widely separated levels in the sun's atmosphere, and that the disturbances do not generally extend over a wide range of heights.

2. *Correlation between many of the larger bursts.* Many of the larger bursts are similar in shape and nearly coincident in time. Bursts which are obviously associated in this way occur occasionally on all three frequencies, more often on the two closer ones. Presumably in these cases the disturbances extend through the requisite range of heights, either because the levels are closer or the disturbances of greater extent.

The majority of such associated bursts occur not simultaneously but in the sequence 200, 75, 60 Mc./s. The observed times of delay show considerable scatter; but, of sixty cases of such associated bursts on 75 and 60 Mc./s., the most common delay is 2 sec. That between 200 and 75 Mc./s. is of the same order, but the value is doubtful, owing to the few cases in which identification of corresponding bursts is possible. In the limited observations on 30 Mc./s., some bursts were observed which occurred a few seconds after similar bursts on 60 Mc./s. This time delay in the occurrence of bursts on different frequencies may be due to selective group retardation of the radiation in its passage through the ionized solar atmosphere, or to the excitation of radiation at successive levels by an agency travelling with finite velocity.

3. *Long time delays between some large outbursts.* Longer delays of several minutes duration have been observed occasionally between outbursts of exceptionally high intensity, in the same sequence 200, 75, 60 Mc./s. An outstanding example was the great outburst of noise on March 8, 1947, which was accompanied by a solar flare and a radio fade-out. On this occasion the recording frequencies were 200, 100 and 60 Mc./s. Our own 200 Mc./s. equipment was out of action, but a record was obtained by Mount Stromlo Observatory and is used here with their permission. There was a delay of 2 min. between the onset of the outburst on 200 and 100 Mc./s., and 4 min. between 100 and 60 Mc./s. The accompanying graph shows the time-sequence of events with the time of the radio fade-out. Observers at Mount Stromlo report that when optical observations commenced at 0440 a flare was in progress and already decreasing, and had disappeared by 0450. Incidentally, the noise intensity observed on 60 Mc./s. (off-scale at 10^{-9} watts/metre^2/megacycle band-width) is the greatest of which we have record.

The successive delays between the onset of the outburst on 200, 100 and 60 Mc./s. suggest that the outburst was related to some physical agency passing from high-frequency to lower-frequency levels. If we assume, following ideas suggested by Martyn[2], that the radiation at any frequency originates near the level where the coronal density reduces the refractive index to zero, we can derive a rough estimate of these heights from electron-density data given by Baumbach[3]. As the outburst showed no circular polarization on either 60 or 100 Mc./s., the ordinary ray has been considered. The electron densities and heights corresponding to the three frequencies are shown in the accompanying table, together with the velocity of the presumed disturbing agency.

Frequency (Mc./s.)	Electron density per c.c.	Height above base of corona (H) in km.	Delay of onset of outburst (ΔT)	Velocity$\left(\frac{\Delta H}{\Delta T}\right)$
200	5×10^8	0	2 min.	750 km./sec.
100	$1{\cdot}2 \times 10^8$	9×10^4	4 min.	500 km./sec.
60	$0{\cdot}4 \times 10^8$	20×10^4		

It is noteworthy that the derived velocities are of the same order as those of prominence material (some hundreds of kilometres per second) and of auroral particles (1,600 km. per second). An aurora was in fact observed in some parts of Australia on the evening of March 9, a little more than a day after the outburst.

This work is part of the research programme of the Council for Scientific and Industrial Research. We are indebted to the Commonwealth Astronomer for information on the solar flare and the 200 Mc./s. noise during the great outburst of March 8, and to the Overseas Telecommunications Commission (Australia) for information on the radio fade-out on the same date. Of our own colleagues we should particularly like to thank Dr. J. L. Pawsey for his interest and helpful discussions throughout all phases of the work.

Residual Lattice Strains in Plastically Deformed Metals

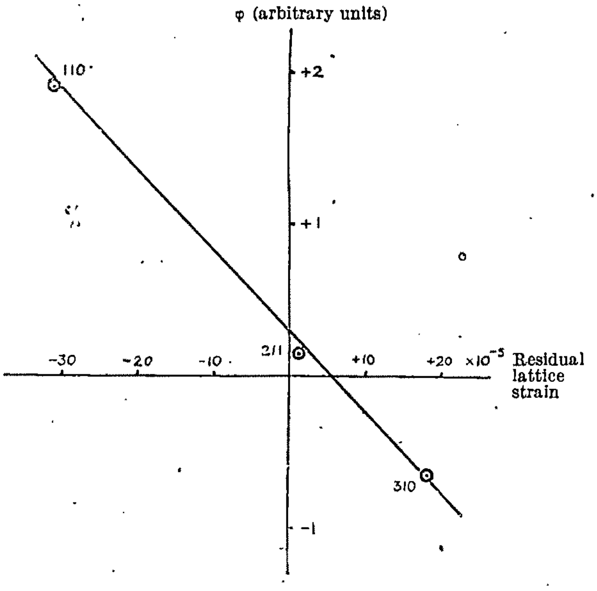
By measuring the change of the atomic interplanar spacing during a tensile (or compressive) test by means of X-ray diffraction methods, the 'lattice strain' can be plotted as a function of the stress. Such stress-*v*.-lattice strain curves, studied particularly by Smith and Wood[1], show that the lattice strain does not vanish when the applied stress is removed from the plastically deformed metal. This residual lattice strain must be due to microscopic residual stresses[2], and an investigation of the residual strains helps to clarify the origin and distribution of these.

In the present communication it is shown that the internal stresses arise mainly from the plastic anisotropy of the metal. The tensile stress required to cause glide in a given grain—the 'yield tension' of the grain—depends on the orientation of the glide planes and glide directions. In a polycrystalline aggregate deforming plastically under a tensile stress, grains with a high-yield tension will carry a greater stress than their neighbours, the orientations of which are such that they glide more easily. On removing the applied load a complicated stress system will arise in the aggregate; grains of high-yield tension will, in general, remain in tension, and those of low-yield tension will be in compression. The X-ray diffraction technique picks out grains of certain orientations, the normals to the reflecting planes being in a direction fixed geometrically by the X-ray beams. The 'residual lattice strain' found from a given X-ray reflexion is not the mean of the strains of all the grains, which is zero, but a mean of the strains of grains with particular orientations. This in general will not be zero; it must be expected to vary with the particular reflecting plane examined, and both positive and negative values should be found, depending on the choice of reflecting plane. On the other hand, an explanation of the residual lattice strain of the type proposed by Smith and Wood[1] would seem to demand that all reflexions should show approximately the same value.

Experimental work carried out to test the validity of the hypothesis outlined was as follows. Annealed metal wires of about 0·5 mm. diameter and extended plastically to the breaking point were photographed in a 19-cm. Bradley–Jay X-ray diffraction camera. Several characteristic X-radiations were used to obtain reflexions at high θ values for as many planes as possible. The strains for each reflecting plane were obtained by comparing the lattice spacings obtained from these photographs with those obtained from photographs taken of the same pieces of wire after re-annealing. The strains were always measured in a direction normal to that of the applied stress. In the results a residual lattice strain of sign opposite to the strain produced by the originally applied stress is denoted positive. Using this convention, the residual strains shown in the curves of Smith and Wood are always positive.

RESIDUAL LATTICE STRAINS FOR VARIOUS REFLECTING PLANES AFTER PLASTIC EXTENSION

Metal	Plane reflecting	Residual lattice strain
Iron	310	$+18 \times 10^{-5}$
	211	+1
	110	−31
Magnesium	$10\bar{1}5$	−3
	$12\bar{3}3$	+3
	$11\bar{2}4$	+2
	$20\bar{2}3$	0
	$10\bar{1}4$	−7
	$20\bar{2}5$	−3
	$12\bar{3}1$	+4
	0006	−5
	$30\bar{3}2$	+2
	$20\bar{2}4$	+3
	$30\bar{3}0$	+4



The table shows the results obtained for iron and for magnesium, the probable error of the residual lattice strains being about 1×10^{-5}.

For iron, a rough estimate of the average yield tension for grains of various orientations can be made from calculations performed for single crystals. If φ denotes the excess of the average yield tension for those grains contributing to a given reflexion over the mean value for all the grains in the aggregate, then it can be shown that a plot of the residual lattice strain against φ for various reflecting planes should be a straight line through the origin with a negative gradient. This graph is shown in the figure.

Similar results have been obtained with copper and aluminium, and it is considered that they afford confirmation of the hypothesis put forward.

The calculations of the yield tension indicate that this quantity varies rapidly with the angle between the applied stress and the reflecting normal. This angle is 90° in the experimental method used here, and about 80° for the usual back-reflexion camera technique; it is impossible to compare results obtained by the two methods. Further work is being undertaken to investigate the possible effect of specimen size and shape on the residual lattice strain.

This work has been carried out for the Royal Aircraft Establishment as part of a programme for the development of the X-ray method of measuring locked-up stresses in fabricated metal parts.

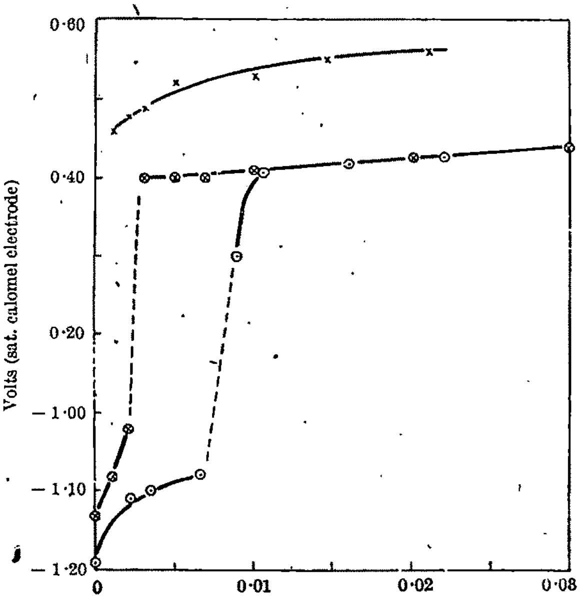
Anodic Behaviour of Mild Steel in Strongly Alkaline Solutions

In connexion with the well-known intercrystalline failure of mild steel in concentrated solutions of sodium hydroxide, it would appear that a study of the anodic behaviour of iron in such solutions might lead to results of considerable interest. A search of the literature soon reveals, however, that but little attention has been devoted to this matter. The work of Grube and Gmelin[1], who carried out a careful and extensive investigation in this field, is therefore of special importance. These workers obtained evidence that anodic dissolution takes place in two distinct potential stages: at low current densities electrolysis proceeds at a potential of about – 0·85 V. (hydrogen), whereas at higher values it changes suddenly to + 0·65 V., when oxygen evolution commences. The critical current density was found to increase rapidly with temperature. Evidence is adduced by Grube and Gmelin that the lower (more negative) potential stage is associated with the formation of ferrous ion, and the higher with oxidation to the hexavalent ion $Fe^{6\cdot}$; anionic complexes being formed having the probable compositions $(FeO_2)''$ and $(FeO_4)''$ respectively.

I have carried out a few exploratory experiments on similar lines, with special reference to the influence of the molality of the solution. I used unstirred solutions, with a vertical electrode, though the degree of agitation and the position of the electrode appear to have little influence in this case. Some results are represented in the accompanying figure. These refer to a dead soft mild steel (0·05 per cent carbon) and were obtained at 80° C. The curves of potential against the saturated calomel electrode are plotted to a base of apparent current density.



ANODIC ELECTROLYSIS OF MILD STEEL IN AQUEOUS SODIUM HYDROXIDE: ×, 1·5 *M*; ⊕, 6·2 *M*; ⊙, 12·9 *M*

A certain amount of instability of the lower potential stage was observed near the critical current density, especially at the lower molalities. Further work indicated that this effect was attributable to the influence of time, in that the electrode tended to become passive at a current density considerably below the supposed critical value, provided sufficient time were allowed; for example, in a 12·9 molar solution, in which the apparent critical current density was about 0·003 amp./cm.², the electrode became passive after 40 minutes at 0·001 amp./cm.², and after 10–12 minutes at 0·002 amp./cm.².

A simple and plausible explanation of the existence and quasi-stability of the lower potential stage seems possible on the following lines. As is customary in such work, and like Grube and Gmelin, I subjected the anode to a previous cathodic polarization in order to remove the air-formed oxide film on the metal. Now experiments in a somewhat different connexion have shown that hydrogen is occluded by iron when the latter is cathodized in strongly alkaline solutions in quantities which increase rapidly with the strength of the solution. It seems probable, therefore, that during the initial stages of anodic polarization this occluded hydrogen will effectively prevent the formation of an adherent oxide film and consequent onset of passivity[2].

It is hoped to supplement these initial results and to publish a fuller account of this work later.

X-Ray Diffraction Studies of Yielding in Mild Steel

SIMILAR results to those described by J. M. Cowley and M. S. Paterson in their communication in *Nature*[1] concerning the examination of 'Hartmann's lines' (also known as 'Lüders' lines') in steel using X-ray diffraction methods were reported by me in 1927 [2], and again in 1937 [3] in consequence of a fuller investigation of steel and 'duralumin'. That was the first time the result of X-ray diffraction studies of 'Hartmann's lines' was published, so far as I am aware. Researches on the subject of 'Hartmann's lines' in steel, including a study of their properties, and of which my first memoir was a part, were carried out in the Department of Metallurgy of the University of Birmingham by Mr. T. Henry Turner, Dr. J. D. Jevons and myself, being under the supervision of the first-named.

A noteworthy disclosure in Messrs. Cowley and Paterson's communication is the presence of a considerable proportion of diffuse spots (indicating distorted crystals) with respect to the metal near a 'Hartmann's line' near the centre of a region of 'Hartmann's lines' but not actually forming any part of a 'Hartmann's line' (see their Fig. 1 and Fig. 2 *d*), whereas almost all the spots are diffuse if the part under examination is all part of a 'Hartmann's line'. Further X-ray diffraction studies of such distortion near 'Hartmann's lines' would be of much interest.

Smears of Titanium Metal

A REMARKABLE phenomenon is shown by metallic titanium when rubbed against many hard surfaces. If a piece of the metal with a rounded end, of radius of curvature about 1 mm., is pressed firmly on to a hard surface and drawn across it, the metal is left behind in the form of a silvery smear. Smears are obtained with greater difficulty on some substances than on others, but only one crystalline material has been found on which no smear is produced (see accompanying table). The titanium metal may be removed by treatment with hot concentrated hydrochloric or sulphuric acids for about half an hour, or by treatment with cold commercial hydrofluoric acid for a few seconds. Some surfaces which were originally smooth and shiny are seen to have lost their polish after the titanium has been dissolved away. In this way, for example, it is possible to remove the polished surface of glass by rubbing with titanium and then dissolving the metallic smear in hydrochloric acid. The table gives a summary of the results obtained on a number of crystalline materials and on glass.

On Moh's scale the hardness of titanium is less than 5, since it is scratched by apatite but not by fluorspar. It will be seen that in the first place we have the result that a material of hardness 5 can destroy the surface of a crystal of hardness 8, namely, topaz[1]. Among the oxides the surface smoothness is affected only with difficulty or not at all, whereas all the silicates except beryl are readily attacked.

Chemical reaction brought about by rubbing two materials together is well known, and these effects may be due to some chemical reaction of the titanium with the materials on which it is rubbed. The readiness with which silicates react suggests that the titanium may enter into the lattice.

The practical applications of the smears may be (*a*) to coat materials with a metallic layer, (*b*) to etch glass without hydrofluoric acid, and (*c*) to form high resistances of the order of 10^{11} ohms; lines drawn on glass form such resistances, and although not stable against all changes of atmospheric conditions, they are sufficiently stable to be useful.

This investigation arose from a suggestion of Mr. J. B. Nelson and was made possible by a gift of a piece of titanium from Mr. H. F. Kay; we gratefully acknowledge this help. We are indebted to the Department of Mineralogy and Petrology for access to the mineral specimens on which the tests were made.

Furansulphonamides

As a recent issue of *Chemical Abstracts* contains an account of the preparation of the sodium and barium salts of furan-2-sulphonic acid[1], by the direct sulphonation of furan, the following report on the indirect production, from pyromucic acid, of simple sulphonation derivatives of furan may be of interest.

The diamide of pyromucic-5-sulphonic acid was prepared, by the method of Hill and Palmer[2], and converted, with barium hydroxide, to furan-2-carboxylic acid-5-sulphonamide

$$C_4H_2O(CONH_2)SO_2NH_2 \longrightarrow C_4H_2O(COOH)SO_2NH_2.$$

Substituted sulphonamido acids were obtained from the dichloride of pyromucic-5-sulphonic acid, as indicated schematically below.

$$C_4H_2O(COCl)SO_2Cl \xrightarrow{CH_3OH} C_4H_2O(COOCH_3)SO_2Cl \xrightarrow{R_1R_2NH} C_4H_2O(COOCH_3)SO_2NR_1R_2 \xrightarrow{NaOH} C_4H_2O(COONa)SO_2NR_1R_2.$$

The above acids were decarboxylated by the method of Gilman and Wright[3].

$$C_4H_2O(COONa)SO_2NH_2(R_2) \xrightarrow{HgCl_2} C_4H_2O(HgCl)SO_2NH_2(R_2) \xrightarrow{HCl} C_4H_3O.SO_2NH_2(R_2).$$

Furan-2-sulphonamide (m.p. 122–123·5°), furan-2-sulphonyl methyl anilide (m.p. 95–98°) and furan-2-sulphonyl-diethylamine, a liquid, were thus prepared.

Furan-3-sulphonic acid and its derivatives were obtained as follows: Pyromucic acid was brominated to the 5-bromo acid, which was sulphonated and the carboxylic group replaced by bromine, as described by Hill and Palmer[4]. The barium 2-5: dibromofuransulphonate thus obtained was treated with zinc and ammonium hydroxide, which replaced the bromine atoms by hydrogen, giving barium furan-3-sulphonate. From this salt was prepared the *p*-toluidine salt (m.p. 172–173°), and the free acid, an oily liquid, which was reconverted into the barium salt, and the *p*-toluidine salt. The impure sodium salt was obtained, in the usual way, and converted into the sulphonic chloride, from which furan-3-sulphonamide (m.p. 106–108°) and furan-3-sulphonylmethylanilide (m.p. 95–97°) were prepared.

A detailed account of this investigation will appear shortly.

Identification of Creatine by Partition Chromatography

IN a study of creatinine metabolism in the rat, to be published elsewhere, creatinine has been identified qualitatively by means of the technique of partition chromatography on paper strips developed by Consden, Gordon and Martin[1]. The apparatus described by Dent[2] has been used, with the further refinement of accurate temperature control obtained by immersing the outer glass container in a water thermostat at 15 ± 0·05° C. Solutions containing *c.* 20–30 γ of creatinine were pipetted on to the paper strips, and after treatment with an appropriate solvent, for example, collidine for 24 hours, the creatinine bands were located by spraying with alkaline sodium picrate.

Some rat urines examined in this manner showed, in addition to a creatinine band, a further Jaffé positive band corresponding to a substance of lower R_f value than creatinine. The second band has since been shown to arise from the creatine, present in the urine, which had undergone movement in the solvent and which had been dehydrated to creatinine during the drying of the paper strips. By means of acid treatment of the strips it is possible to convert creatine more completely to its anhydride *in situ*, and in this way to determine R_f values for creatine.

Further, this procedure affords a method for determining creatine qualitatively in the presence of creatinine, the method adopted being as follows: the test material is pipetted on to the strip and is treated with the appropriate solvent. The strip is dried at 100° C., sprayed with 0·5 N sulphuric acid and again heated at 100° C. for 1 hour. Creatine is located on the strip as creatinine by spraying with alkaline sodium picrate. R_f values determined at 15° C. for creatine and creatinine (solvent collidine) both in pure solutions and in rat urine are given in the accompanying table.

	Pure solution	Rat urine
Creatine	0·19	0·15
Creatinine	0·47	0·57

Each figure represents an average of at least six values, the maximum variation obtained being 9 per cent. The R_f values for creatine are sufficiently far removed from those of creatinine to enable clear-cut separation of these substances, and it is therefore possible to identify creatine qualitatively in the presence of considerable amounts of its anhydride.

Further solvents giving suitable R_f values for these two substances are being tried. Creatine and creatinine in phenol move as fast as the solvent. Creatinine shows no movement in amyl alcohol, but has a low R_f value in n-butyl alcohol (creatinine in pure solution: 0·20; creatinine in rat urine: 0·25).

Enzymatic Hydrolysis of Cellulose by *Coniophora cerebella*

DURING the course of the investigation of the enzymatic activities of wood-destroying moulds[1], an attempt was made to depict the phase sequence of the degradation of the cellulosic fraction of wood; cellulose itself, in the forms of filter paper and surgical cotton, was utilized. *Coniophora cerebella* was found to degrade both forms of cellulose to oxalic acid. Inasmuch as traces of reducing material were found to be formed, and oxalic acid was also obtained by the action of the fungus on glucose, it appeared that an introductory hydrolysis was a necessary prerequisite for the formation of oxalic acid.

A hydrolytic action being involved, it was found useful to examine the residual cellulosic material to determine whether there was an increase or decrease in reducing power. If one were to assume that a hydrolysis similar to that by acids took place, then there would be an increase in reducing power due to the formation of new reducing groups. On the other hand, a split of semi-acetal bonds, the existence of which was first surmised by Tollens, might take place, with the result that the residual material would show a lower reducing value.

Some experiments by Hiller and Pacsu[2] indicated that an *initial* rapid acid hydrolysis of cellulose causes a split of semi-acetal bonds, permitting a *decrease* in reducing power. Consequently, speculation arose whether an enzymatic degradation of cellulose would follow such a pattern, or whether the mould effects a split of 1,4-glycosidic bonds to give rise to new reducing groups.

Surgical cotton which was degraded by *Coniophora cerebella* over a period of sixty days was examined at certain intervals, employing the analytical technique of Hiller and Pacsu, which requires the use of dilute acidic permanganate solution for the determination of reducing power. An inspection of the values recorded in the accompanying table indicates an *increase* in reducing power of the residual cellulose as the oxalic acid content increases:

DISSIMILATION OF SURGICAL COTTON BY *Coniophora cerebella*

Incubation period Days	Oxalic acid (mgm.)	Milli-equivalents oxygen used up
0	0	0·0500
13	2·35	0·1201
30	6·30	0·2612
60	6·40	0·2668

Values expressed per 1 gm. samples of surgical cotton.

It would appear that the *enzymatic* degradation of cellulose effects a split of 1,4-glycosidic bonds rather than, or concomitant with, a split of semi-acetal linkages.

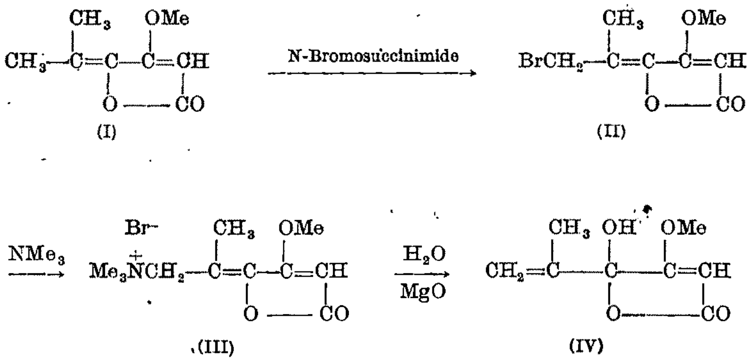
Synthesis of the Antibiotic, Penicillic Acid

PENICILLIC acid, first isolated by Alsberg and Black[1] from *Penicillium puberulum* Bainier and later by Birkinshaw, Oxford and Raistrick[2] from *Penicillium cyclopium* Westling, was shown to possess the structure (IV) by the latter authors. Later it was observed that the compound was a powerful antibacterial agent, and Oxford[3] has determined that it is much more active than penicillin against Gram-negative organisms.

Penicillic acid has now been synthesized from the lactone (I)[4] as follows:



Treatment of (I) with N-bromosuccinimide gives the bromolactone (II) which, on warming with aqueous trimethylamine, yields the quaternary bromide (III). On boiling an aqueous solution of (III) with excess magnesium oxide, trimethylamine is evolved and penicillic acid (IV) is produced directly. The yields in all the above stages are substantially quantitative.

The mechanism of the last step is formulated thus. The quaternary bromide is first converted to the quaternary hydroxide, which then undergoes the rearrangement already encountered in this field[4]. This has the net effect of adding the elements of water across the double bond. Finally, occurrence of the familiar Hofmann reaction leads to penicillic acid.

The melting point of the synthetic acid is 86–87°, undepressed on admixture with the mould metabolic product; the acetyl and dibromo-compounds likewise give no depression in melting point when mixed with the corresponding derivatives prepared from the natural product. The natural and synthetic acids exhibit identical light absorption properties in the ultra-violet.

The last stages of the above synthesis were carried out during the tenure of an Imperial Chemical Industries Fellowship awarded by the University of London.

Interpretation of the Exchange of Radio-Sodium in Isolated Muscle

KROGH, in his Croonian Lecture[1] before the Royal Society, considered the apparent impermeability of striated muscle to sodium to be due to an active extrusion of sodium ions. Discussing this view, Conway[2] calculated the minimal energy required for extrusion of sodium from the normal frog's sartorius if sodium entered as fast as potassium. The result was that more than the energy available from the metabolism of the resting muscle would be needed.

In our experiments, isolated frog sartorii were equilibrated with radio-sodium, and the washing out of the isotope was followed. We found that the exchange of the sodium of the muscle fibres with that of the outside medium occurs very rapidly. After correcting for interspatial sodium, it turned out that half the sodium of the fibres was renewed in about half an hour. The use of Ringer solution with high potassium content (12·5–30 mmol.) gave similar results. When the sodium content of the muscle fibres is known, it is possible to calculate the absolute amount of sodium entering and leaving the muscle fibres per unit time; and in the experiments with high potassium these two values differ but slightly. Using Conway's formula (*l.c.*) the rate of passage of sodium corresponds to more than 150 cal. per kgm. per hour at the actual ion concentrations of the experiments, if the exchange of sodium were a true measure of the sodium transported out.

There are, however, certain mechanisms which will allow an exchange of sodium ions between two phases at different concentrations without consumption of chemical energy. In the first place, an exchange without change in concentration may, of course, take place if the difference in concentration is maintained by an electric potential difference; for example, in the case of a Donnan equilibrium. But this cannot be the explanation in the case of the muscle, where the sodium moves out against the potential gradient, the interior of the cells being negative relative to the surrounding medium. In search for a reasonable explanation we may, for example, imagine the cell membrane as an oil layer with suspended particles of some 'Permutite' with an especially high adsorption affinity for sodium. The inside medium may contain radio-sodium at a low concentration, and the outside may contain ordinary sodium at a high concentration. We suppose that the Brownian movements bring one of the 'Permutite' particles into contact with the inside medium. Inactive sodium will then be exchanged with active; later, the particle may come in contact with the outside medium, and the active ions may be given off to this medium in exchange for ordinary ions. In this way, the statistical approach to an equal proportion between active and ordinary sodium ions on both sides of a membrane may proceed at a much higher rate than the approach to equal concentrations on both sides. This is only one of several possible mechanisms which will give the same result; as will also, for example, Lundegårdh's concept[3] of the cell membrane containing acid and basic groups which bind ions of the opposite charge and which sometimes turn round so that they are alternately in contact with both surfaces.

The muscle where the sodium passes out against a concentration gradient as well as against the electrical potential represents a case in which a mechanism similar to that outlined above seems the most reasonable explanation of the experimental facts. However, it must be pointed out that, generally, tracers cannot be used to measure the active transport of ions across a membrane without paying due regard to the fact that part of the apparent transport may be simple exchange.

A detailed account of the tracer experiments performed at this Laboratory will be published in the near future.

'Aerosporin', an Antibiotic Produced by *Bacillus aerosporus* Greer

A BACTERIUM isolated from the soil of a market garden in Surrey during February 1946 and afterwards from a Yorkshire soil and from the air has been found to produce an antibiotic of possible therapeutic importance for which, as it appears to be hitherto undescribed, the name 'Aerosporin'* is proposed. The production and properties of aerosporin are under investigation by a group of workers at the Wellcome Physiological Research Laboratories, and the purpose of the present communication is to direct attention to certain aspects of these studies, the results of which will be published in detail elsewhere.

The organism, a Gram-positive, spore-forming rod, has been identified by Mr. H. Proom with that described by Greer[1] from Chicago tap water as *Bacillus aerosporus*. *B. aerosporus* is considered by some authorities to be synonymous with *B. polymyxa* (Prazm.) Migula, and of three cultures so designated from the National Collection of Type Cultures, two (N.C.T.C. 4747, which originated from the Chicago Board of Health as *B. aerosporus*, and 1380) proved to possess similar antibiotic-producing activity, while one (N.C.T.C. 4745, from the United States and originally designated *B. asterosporus* (Meyer) Migula) did not.

The organism grows well in nutrient broth, but more satisfactory yields of antibiotic are obtained from half-strength broth to which sucrose or glucose and a trace of manganese has been added. In shallow layers at 28° C., the organism grows at the bottom of the culture fluid, where more or less mucilage is formed, depending on the choice of strain and medium. The antibiotic titre increases for four to seven days and then declines.

Aerosporin is a base, and methods for its extraction are similar to methods for streptomycin. Because the activity of the culture fluid is reduced by passage through a candle or a Seitz filter, the bacterial cells are removed by centrifugation. A convenient extraction procedure is one developed by Dr. C. G. Pope from the method for extracting streptomycin described by Van der Brook *et al.*[2] by which the aerosporin is adsorbed on to a suitable activated charcoal, the charcoal treated with dilute sulphuric acid, and the antibiotic eluted with aqueous acetone. The crude aerosporin sulphate is precipitated by the addition of dry acetone.

As described below, aerosporin is active against Gram-negative organisms, and the routine method for its assay has been a dilution method using *Escherichia coli* as the test organism. Two variants of the test have been used. In one the tests are read after approximately three hours incubation at 37° C.; in the other, after incubation overnight at 28° C.

Aerosporin is selective in its action against Gram-negative organisms. Among the more interesting of the pathogens against which it has proved chemotherapeutic in experimental infections in animals are *Hæmophillus pertussis*, *Eberthella typhosa* and *Escherichia coli* in the field of human medicine, and *Brucella bronchiseptica* and *Escherichia coli* strains of 'calf scour' in the veterinary field. The antibiotic is bactericidal in action, and, where attempted, cultural methods have failed to produce resistant strains.

Aerosporin is readily produced, is relatively stable, and in addition to its selective action is of high intrinsic potency. Weight for weight it has the same order of chemotherapeutic activity against Gram-negative organisms as has penicillin against Gram-positive.

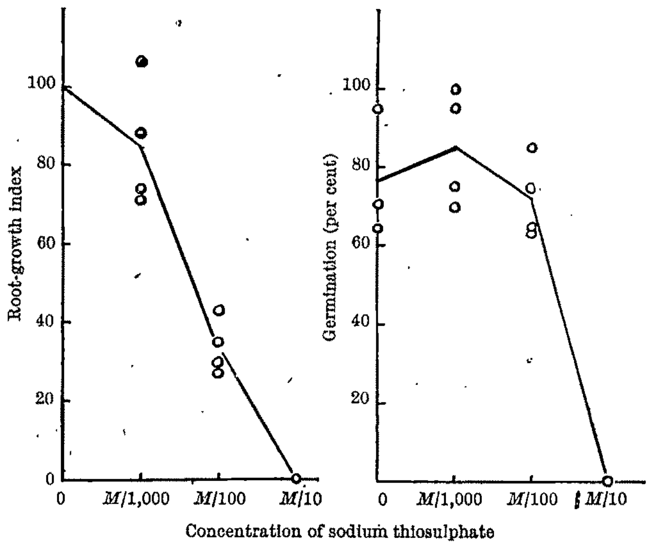
Selective Toxic Action of Thiosulphate on Plants

INVESTIGATIONS have been recently carried out on the effects of low concentrations of sodium thiosulphate on the germination and subsequent root growth of a number of plants. (These investigations were undertaken as a result of earlier work, not yet published, by Quastel, Hewitt and Nicholas, on the effects of thiosulphate on growth of crops in soils.)

The experiments were carried out with sterile seeds grown under rigidly sterile conditions by a technique recently described[1,2]. Three concentrations (namely, $M/1{,}000$, $M/100$ and $M/10$) of thiosulphate, together with controls, were used in normal culture solutions. Concentrations and controls were usually set up in triplicate, samples of 10–20 seeds being used in each tube or set of tubes. After a period of 7–10 days growth at 20–22° C. in artificial light (9 hours per day) the percentage germination and total weight of roots produced were found for each concentration. From these figures the 'root-growth index' (ratio of average weight of roots per seedling in thiosulphate solution to average weight of roots per control seedling multiplied by 100) has been calculated, and this gives a direct indication of root-growth inhibition by thiosulphate. This provides a rigid separation of the two effects (namely, on root growth and on germination).

Results for experiments on cress (*Lepidium sativum*) are seen in the accompanying figure, where root-growth index and percentage germination are plotted against a logarithmic scale of increasing thiosulphate concentrations. The straight lines join the mid-points of the observed values for each concentration. By interpolation, the concentration of thiosulphate necessary for 50 per cent inhibition of both root growth and germination can be roughly estimated. With cress these concentrations are $4{\cdot}7 \times M/1{,}000$ and $26 \times M/1{,}000$ for root growth and germination respectively.



GRAPHS SHOWING EFFECTS OF VARIOUS CONCENTRATIONS OF SODIUM THIOSULPHATE ON ROOT GROWTH AND PERCENTAGE GERMINATION OF CRESS (*Lepidium sativum*)

Similar calculations have been made from graphs constructed for other species investigated. These results appear in the accompanying table. Here the plants are arranged in order of decreasing sensitivity, judged on their root growth. It will be seen that there is a considerable range of sensitivity, from garden pea at the sensitive end of the scale to carrot at the insensitive end. On the whole, much higher concentrations are necessary to produce the same degree of inhibition of germination. Thus thiosulphate shows a considerable degree of selectivity in its toxic action on the growth of plant roots.

Plant	Concentrations producing 50 per cent inhibition	
	Of root growth	Of germination
Garden pea	$4 \cdot 0 \times M/1{,}000$	$31 \cdot 0 \times M/1{,}000$

Mustard	27·0 ,,	15·0 ,,
Carrot	41·0 ,,	38·0 ,,

The effects of two other sulphur compounds, sodium dithionate and potassium trithionate, on cress have been investigated. Neither of these compounds is as toxic as sodium thiosulphate, the concentrations necessary to produce 50 per cent inhibition of root growth being $39 \times M/1{,}000$ for dithionate and $53 \times M/1{,}000$ for trithionate (compared with $4 \cdot 7 \times M/1{,}000$ for thiosulphate).

It is hoped that experiments now in hand may elucidate the mechanism of these inhibitions.

Symbiosis in *Oliarius*

MAHDIHASSAN[1] has recently criticized my interpretation of symbiosis in the Fulgorid insect *Oliarius cuspidatus* Fieb., described by Šulc[2] in 1924. He states that what I interpreted as a mycetome is in fact the testis, the contents being spermatozoa rather than bacteria.

A glance at Šulc's figure, reproduced by Mahdihassan, should be a sufficient demonstration of the untenability of Mahdihassan's position. The object in question, which Šulc unfortunately called the 'interfollicular organ', has no efferent duct and is not composed of follicles. It is formed of a strange syncytium like that found in the bacterial-containing organs of cicad insects, with a low covering epithelium which sends thin septa into the cavity. This cavity is filled with long slender threads with scattered metachromatic nuclei in which all characteristics of sperm are lacking and which, without question, are bacteria.

Moreover, these so-called 'testes' are found in both sexes; and contrary to what Mahdihassan states, they have not been studied in this particular case alone. A pupil of mine, G. Richter[3] was able to study another species, *Oliarius horisanus* Mats., from Formosa, and found precisely the same type of complicated symbiotic arrangements in the female. Another pupil of mine, H. J. Müller, in his large "Monographie der Fulgoroiden-Symbiose", based on not less than 173 species, finds the same organs in both sexes of several species of *Oliarius* *O. panzeri* P. Löw, from Germany, *O. tantalus* Gifford from Hawaii, *O. villosus* F. and other unidentified species, from Brazil.

It was thus scarcely necessary for Mahdihassan to spend months at Brno, where Šulc made his studies collecting material of a very rare species, to prove me guilty of so gross an error.

Inhibition of the Toxicity of 'Gammexane' for Insects

DURING the course of work on the effect of 'Gammexane' (pure gamma isomer of hexachlorocyclohexane) on the metabolism of fat, protein and carbohydrate by fourth-stage mosquito larvæ, it was observed that the concentration of 'Gammexane' tolerated in the presence of fat (olive oil) was higher than that in the presence of protein or carbohydrate. Further experiments with fourth-stage larvæ of *Aedes ægypti* and *Culex fatigens* confirmed this finding, and it was observed that liquid triglycerides in general provide a degree of protection for larvæ against 'Gammexane'. The findings of Buxton[1] and Upholt[2] indicate that this may be a similar phenomenon to that which results in the inactivation of D.D.T. when applied as a larvicide under natural conditions, suggested by Upholt to be due to adsorption by the organic constituents of mud.

The accompanying graph shows the effect of triolein (mixed in 5 per cent concentration on 0·1 gm. of kaolin) in reducing the mortality of larvæ exposed to
